THE REGISTERS OF PHARMACEUTICAL CHEMISTS AND CHEMISTS AND DRUGGISTS, 1894.

Additions during the year:—

Number of persons who have passed the—

Minor ........................................ 524

Major ....................................... 74*

Number of persons restored to the Register on payment of a fine ........................................ 18

Number of persons registered on payment of the registration fee, having been in business before August 1, 1888 ........................................ 3

540

Erasures during the year:—

Deaths .................................................................. 253

Erased at the request of registered persons themselves ........................................ 3

Erased by the Registrar in pursuance of the provision set forth in Section 10 of the Pharmacy Act, 1868, after sending two registered letters, to which no answer has been received ........................................ 246

Increase of numbers on the Register ........................................ 38

540

* These having already been included in the number who passed the Minor, do not increase the numbers on the Register.

Number of Pharmaceutical Chemists on the Register, December 31st, 1894 2,840
Chemists and Druggists ........................................ 19,898

14,898
ELECTION OF ASSOCIATES IN BUSINESS.
The following having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:

Minor.

Baker, William Weaver ....... Brookley.
Coleman, John Harold ....... Wolverhampton.
Davies, David John .......... Swansea.
Bremner, Daniel Thomas ....... Margate.
Fletcher, John .................. Ashby.
Hannah, Henry ................. Palaley.
Hemingway, Edward ........... London.
Hirst, Edward ................. Colne.
Hough, Thomas ............... Northwich.
Johnstone, James ............ London.
Kirkpatrick, James ........... Tunstall.
Lawes, David Llewelyn ....... Ealing.
Moir, David .................. Glasgow.
Otty, William Hare .......... Birmingham.
Peterkin, James .............. Lowestoft.
Richardson, Sylvester ....... Stockton-on-Tees.

Modified.

Bass, Charles Murfreet ....... Ragley.

ELECTION OF ASSOCIATES.
The following having passed the Minor examination, and tendered or paid, as Students, their subscriptions for the current year, were elected "Associates" of the Society:

Bennett, Sidney Bailey ....... Widnes.
Branch, George Thomas ....... Cambridge.
Dancy, Ralph .................. Leeds.
Fisher, George William ....... Stockton.
Gordon, John Alexander ....... Edinburgh.
Green, James .................. Peterborough.
Holroyd, James ............... Ashton-under-Lyne.
Lacy, Arthur Edward ......... Hackney.
Marshall, Gervas Gilbert ....... Cheadle.
Nall, Walter .................. Rochdale.
Smith, Philip .................. Luton.
Thomas, Hugh Wolseley ....... Bisconvile.
Tina, Edgar Orlando .......... Leicester.
White, Alexander Arthur ....... Edinburgh.
Wilkinson, George Henry ....... Dudley.
Williams, George Alfred ....... Shrewsbury.
Wilson, William Wood ......... Glasgow.
Wright, Charles George ....... London.
Wyatt, Frank Leopold ......... Manchester.

ELECTION OF STUDENTS.
The following having passed the "First" examination, and tendered their subscriptions for the current year, were elected "Students" of the Society:

Ashford, Frederick Charles .... Northampton.
Attenborough, H. Langley .... Leamington.
Barnett, Henry ................. Folkestone.
Bastow, Sidney ................. London.
Bignell, John Henry .......... Twyford.
Bramall, George Oliver ....... Burnham.
Burgess, Frederick William .... Bradford.
Cooper, James .................. Leicester.
Doughty, Thomas Herbert ....... Lewisham.
Dyson, Thomas Hatsfield ....... Ilkley.
Eills, John .................... Leicester.
Ellis, Lawrence ............... Norwich.
Forster, Horace Reginald W. ... Chatham.
Fox, Robert ................... Norwich.

Hardcastle, Edward .................. Stockport.
Hardy, Thomas .................. Sutton-in-Ashfield.
Hudson, Sidney Charles ....... London.
Jenkins, Gwilym Rees ......... Swansea.
Jones, John Daniel ........... Aberythwyth.
Lloyd, John Ambrose .......... Chester.
Morrei, John George ........... Stockton-on-Tees.
Roberts, Joseph .............. Kingsthorpe.
Rushton, William Burton ....... Walkden.
Saunders, Alfred Woods ....... Maldon.
Simnett, Herbert Frank ....... London.
Sparks, Percy .................. Lowestoft.
Spencer, William Crubing ....... Wycombe.
Thorpe, Arthur Muxlow ........ Spalding.
Turner, Alfred William ....... Westbury-on-Severn.
Wilson, Harold ............... Bridlington.

RESTORATIONS TO THE REGISTER.
The name of the following person, who has made the required declarations and paid a fine of one guinea, was restored to the Register of Chemists and Druggists:

Thomas Broom, Sunderland Street, Houghton-le-Spring.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a restoration fee of one shilling.

REGISTRAR'S REPORT.
The Registrar's report on the numerical strength of the Society was laid on the table. It is printed at pp. 670, 671.

FINANCE COMMITTEE.
The Secretary read the report of this Committee, which was of the usual character, and recommended sundry accounts for payment.

The President (as Chairman of the Committee) moved the adoption of the report. On the Benevolent Fund £89 had been received as subscriptions, and certain ground rents and dividends, including that on the St. Paul, Minneapolis, and Manitoba Railway bond, presented some time ago by Mr. Burroughs. On the donation account £10 had been received from Professor Michael Foster.

The report was unanimously adopted.

The President added that the Secretary had received a letter stating that the late Mr. Hooper had left a legacy of £100 to the Benevolent Fund. He was sorry to add that Mrs. Hooper had died very shortly after her husband.

BENEVOLENT FUND COMMITTEE.
The report of the Committee included recommendation of the following grants:

£25 to a registered chemist and druggist (51), who had two grants of £25 each in December, 1892, and February, 1894. He is quite unfit for work, his sight and hearing being very defective. He and a daughter of fourteen rely on what the wife can earn by charging and laundry work. (Greenwich.)

£10 to the widow (51) of a member, and former subscriber. She had a grant of £10 in February, 1893, and a similar amount in February last. She is suffering from chronic rheumatic arthritis, and is able to do very little work. (Brixton.)
The further consideration of one case was deferred. Mr. Bottle (as Chairman of the Committee), in moving the adoption of the report and recommendations, said fortunately the applications for relief were very light during the last month. Amongst them was the case of Mr. John Owen, an old friend of many of the Council, and a former colleague, who unfortunately had fallen into such circumstances as to require aid, but by a wise dispensation of Providence he was taken away before the application could have been considered. It would have been a very painful duty for the Committee to deal with such a case, and he really felt glad that they had been spared the task. The other cases did not call for any comment.

The resolution was carried unanimously.

REPORT OF THE LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

Library.

The report of the Librarian had been received, including the following particulars:

<table>
<thead>
<tr>
<th>Attendance</th>

Donations to the Library had been announced (Pharm. Journ., January 19, p. 612), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended that the undermentioned works be purchased:

For the Library in London—
Carnegie, Law and Theory in Chemistry.

For the Library in Edinburgh—
Bemington, Practice of Pharmacy, 3rd ed.
Kerner and Oliver, Natural History of Plants.
Bower and Vines, Practical Botany.
British Pharmacopoeia, with Additions, 3 copies.
Attfield, Chemistry, 15th ed.
Eliot, Laboratory Course of Pharmacy.

Museums.

The Curator's report had been received, including the following particulars:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Donations to the Museum had been announced (Pharm. Journ., January 19, p. 612), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The President, in moving the adoption of the report, said the formal business spoke for itself. There were applications from Pharmaceutical Societies at Sheffield and Inverness for aid, and they had been deferred in order to give the Committee the opportunity of conferring with Mr. Newholme and their friends from the North.

The resolution for the adoption of the report was carried unanimously.

LAW AND PARLIAMENTARY COMMITTEE.

The President announced that this Committee met and, in pursuance of the resolution carried at the last Council meeting, considered and discussed such matters pharmaceutical as came under the Committee's cognizance. In the end it was thought desirable to adjourn the discussion before presenting a report to a future meeting of the Council.

DIVISIONAL SECRETARY.

The President announced that Mr. Dymott, Divisional Secretary for Deptford, who was retiring from business, desired to resign his official position. He begged to move that Mr. W. Baker, of Lewisham High Road, be appointed Divisional Secretary for Deptford, in his place. He thought Mr. Baker was a very suitable man from the credentials which had been sent in.

The resolution was at once agreed to.

LOCAL SECRETARY.

Mr. Frederick Carter, of Carshalton, was appointed Local Secretary for the Carshalton District.

CERTIFICATE IN LIEU OF THE PRELIMINARY EXAMINATION.

The President said the Secretary had received an application from a German gentleman who desired to enter for the Minor examination, and in lieu of passing the Preliminary examination he had sent in a certificate from the Real-lyceum of Gmünden. It was a much superior examination to anything the Council required, and the Board of Examiners were perfectly prepared to accept it, but could not do so without the authority of the Council. He would therefore move that the Council approve of the certificate being received.

Mr. Warren said he presumed one of the subjects included in the examination was English.

The President said it was. The gentleman in question had been some years in England.

The resolution was carried unanimously.

The President then said he had passed over the Benevolent Fund report somewhat rapidly, and Mr. Atkins desired to add a few words with respect to a reference in that report.

Mr. Atkins said he thanked the President and Council for allowing him somewhat irregularly to say that he could not allow the opportunity to pass without paying his tribute of respect to the memory of Mr. Owen, who, when he (Mr. Atkins) came on the Council of this Society, was doing much good and energetic work, particularly as regarded their orphans, and so anticipated the commendable and excellent efforts so ably inaugurated by the generosity of their late friend, Mr. Hyde Hills. The fact that Mr. Owen died in impoverished circumstances was no reason why they should not remember that, when in affluent circumstances, as he once was, to his knowledge he freely dispensed charity, and extended to
many a hospitality and welcome in his home. That he remembered Mr. Owen as a warm-hearted and generous man, who exerted himself in behalf of objects with which they could all sympathise, was his excuse, in presence of the rapidly disappearing number of old members on the Council, for referring with a feeling of respect and sympathy to one who would be to many now present a stranger.

SALE OF DRUGS IN AUSTRIA-HUNGARY.

The President read a letter from the Privy Council, forwarding copy of a letter which the Foreign Office had transmitted to the Privy Council, with copies of the regulations for the sale of pharmaceutical drugs in Austria-Hungary, and asking to be furnished with any similar regulations which might be in force in the United Kingdom. Accompanying this letter was a copy of the regulations in question, and an intimation that the Lord President proposed to send to the Foreign Office, for the information of the Austro-Hungarian Government, a copy of the Register of the Pharmaceutical Society, which, it was presumed, contained all the regulations in force relating to the sale of drugs in Great Britain, and asking for a copy of the latest edition of the Register.

The President said this request would be complied with. Different bodies throughout Europe already had their regulations, and of course they were glad to give any assistance in such matters.

The President also read a letter from the Deputy-Coroner for North Derbyshire, to the effect that he had sent to the Privy Council a recommendation that carbolic acid be added to the list of scheduled poisons. The President added that the letter would be acknowledged, with an intimation that the Privy Council was the proper authority to be appealed to in the matter.

GENERAL PURPOSES COMMITTEE.

The Secretary read the report of this Committee, omitting the legal portion. The Committee had considered the communication from the Medical Council received last month, and recommended that the following gentlemen be appointed a committee to carry out the work in connection with the new edition of the Pharmacopoeia:—The President, Vice-President, Dr. Inglis Clark, Professor Greenish, Messrs. Ekin, Walter Hills, Martin, Martindale, and Charles Umney; Professor Greenish to be requested to act as Secretary of the Committee. The President reported that he had invited Mr. Peter Squire to join the Committee, but owing to pressure of work he was unable to allow himself to be nominated. A case of alleged personation at one of the examinations in Scotland had been reported, and the Committee recommended that the matter be left in the hands of the President to take such action as he might deem desirable.

The President said he should have to move the adoption of the report later on, but before doing so he might say a word with regard to the appointment of the Pharmacopoeia Committee. It would be remembered that the President of the Medical Council, Sir Richard Quain, addressed him a letter which was referred to the Committee for consideration. He had also received a second communication from Sir Richard Quain, expressing his pleasure at what had been done. Although it was a semi-private letter, he thought he might say it was in complimentary terms, encouraging the Council to do what work they could to the best of their ability. The Committee, after careful consideration, felt that, as the first part of the work was the collection of statistics, it was desirable not to have the Committee too large. They consequently appointed the same gentlemen who were appointed the Committee for the preparation of the Addendum to the Pharmacopoeia, with the addition of Mr. Walter Hills in the place of the late Mr. Gale. In recommending these gentlemen, the Committee was quite sensible that later on it would be necessary to strengthen them by the addition of a certain number of excellent men from the country, without whose assistance the work could not be said to be complete.

The reference in the report to Mr. Peter Squire would have been noticed. All at that table would feel that a man who had given so much time to Pharmacopoeia criticism, and who had spent so much time in experiments in connection with the compilation of his well-known work, ought to be invited to join the Committee, and accordingly he had been so invited. But, as stated in the report of the Committee, he felt unable to allow himself to be nominated, in consequence of the continuous personal work involved in the preparation of the 'Companion.' They would all regret that it was not possible for Mr. Squire to act with this Pharmacopoeia Committee, but knowing how much work he had in hand, he could well understand how difficult it would be for him to give the time required for continuous work on such a Committee. He need only add that he hoped this Committee would approach the work in an enthusiastic spirit, and that the result of its efforts and systematic work properly directed, and with the assistance and co-operation of the Medical Council, would be a distinct advance on any previous edition of the British Pharmacopoeia.

With reference to the alleged personation case, obviously personation was one of the things with which they should deal, with the view of punishing offenders. One such case was proceeding, as many of them might have noticed; but judgment was not yet given, and the Committee thought it desirable that, as a precaution, the President should be authorised, with the advice of Mr. Morrison, the solicitor, guiding him, to take such steps as the judgment might possibly make it desirable, though of course any such steps might prove unnecessary.

The Council then went into Committee to consider the legal portion of the report.

On resuming, the report and recommendations were unanimously adopted, and a resolution was passed authorising the Registrar to take proceedings against the persons named.

Twenty-seven certificates were received in lieu of the Society's Examination.

### FIRST EXAMINATION, RESULTS.

A meeting of the Board of Examiners for England and Wales was held on Tuesday, February 5th. Certificates by approved examining bodies were received from the undermentioned in lieu of the Society's examination:—

- Goshawk, Alick Henry...Cheltenham.
- McGhie, John Knowles...Liverpool.
- Walls, Sydney Wilson...Marlow.
- Williams, John Charles...Balham.

The report of the College of Preceptors on the examination held on January 3rd was received. Three hundred and forty-five candidates had presented themselves for examination, of whom one hundred and eighty-seven had failed.

The following one hundred and eighty passed, and the Registrar was authorised to place their names upon the Register of Apprentices or Students:—

- Adams, Ernest Charles...Salford.
- Alexander, William...Banff.
- Arnds, William...Edinburgh.
- Atterbury, William Richard...Hampton.
- Baker, Henry Charles...Lowestoft.
- Barker, Sidney Francis...Cambridge.
- Barber, Henry...Becap.
- Butterworth, John...Truro.
- Beaton, Gordon...Dufftown.
- Benson, Fenwick Alfred...Stockton-on-Tees.
- Beresford, Arthur William...Birmingham.
- Berry, Edward John...Linlithgow.
- Berry, Walter...Halifax.
- Blockley, Frederick George...Leicester.
- Booker, Charles W. F...Hertford.
- Boon, John Harold...Atherstone.
- Boothroyd, Frederick...Huddersfield.
- Bonthwick, George...Thornhill.
- Bowie, John Alexander...Alloa.
- Bowman, Edward...Benkers Hill.
- Brown, Neilson...Loanhead.
- Barohnall, John William...Uppingham.
- Butterworth, Alfred...Stalybridge.
- Campbell, William J. F...Nairn.
- Carter, Charles Edward...Bradford.
- Christie, James...Ayr.
- Clark, John William...Glasgow.
- Clagg, Thomas Cooper...Hull.
- Cleworth, John...Leigh.
- Coles, Sydney Geo. Reading...Birmingham.
- Cooper, Harry Percival...Wimbledon.
- Crooks, Arthur Thomas...St. Helens.
- Davies, John Alfred...Hersfield.
- Day, Victor Moore...St. Augustin.
- Deacon, Charles Henry...Shipley.
- Dring, Tom...Long Sutton.
- Dunford, Albert John...Downsia.
- Fox, Frederick...York.
- Gauld, James Edward...Edinburgh.
- George, Hugh Benjamin...Fisheguard.
- Gilmour, David...Edinburgh.
- Gowans, James Hornal...Belfast.
- Gowland, George...Newcastle-on-Tyne.
- Graham, Robert...Kirkintilloch.
- Grant, George...Grantham.
- Gray, Clement...Melbourne.
- Green, Frederick Charles...Havant.
- Greenwood, Frank...Healey.
- Greenwood, Frederick...Skegness.
- Grieve, William Charles...Nantwich.
- Haig, Henry George C...Edinburgh.
- Harrison, Sarah S...London.
- Heath, Wallace Evans...York.
- Hicks, George...Rothesay.
- Hill, Lionel Watson...Lincoln.
- Hitchen, Clement Farnell...Halifax.
- Horton, Alfred James...Maidstone.
- Houlton, Jose Leighton...Hal.
- Howard, John E...Grimsby.
- Hughes, Albert Inman...Beaumaris.
- Hughes, Charles James Allen...London.
- Hunter, Peter...Haddington.
- Hutcheson, James Cameron...Lochee.
- Irish, Harry Toose...Lowestoft.
- James, Edward Boul...Birkenhead.
- James, Idwal...Forthcawl.
- Johnson, Frank Horace...Birmingham.
- Jones, David Richard...Bridgend.
- Jones, Richard Owen...Clayton.
- Kay, John Hunter...Canmove.
- Key, R. Coll...Barrow-in-Furness.
- Kendal, John William...Sunderland.
- Kinder, John Henry...Manchester.
- Lambeth, Herbert...Southampton.
- Lancaster, Thomas Edward...Carnforth.
- Langburn, Herbert John...Guisborough.
- Lawrence, Edmund William...Kearesborough.
- Lee, Arthur...Scarborough.
- Lee, Henry Cathbert...Skegness.
- Lillie, Robert...Gateshead-on-Tyne.
- Linnet, Louis John...Sevenoaks.
- Lloyd, Margaret Annie...Birmingham.
- Loveless, John Henry Frank...Bristol.
- Lummis, Harold...Chester.
- Maddox, David Crisp...Skipton-u.-Wychoad.
- Mallagh, Thomas Henry...Brentwood.
- Mansfield, Frank...Nottingham.
- Marshall, Gerald Arthur...Barrow.
- Mayson, Edward...Keele.
- Merry, Edward Lee...Dedelham.
- Millar, Benjamin...Darlington.
- Milne, Alexander...Fettercairn.
- Milne, W. Parfquhar...Aberdeen.
- Missen, Frederick James...Cambridge.
- Mitchell, William Charles...Fowey.
- Morgan, Arthur James...Pwllgass.
- Morgan, Richard James...London.
- Morrise, John...Whitby.
- Neill, Ernest Alfred...Didsbury.
- Newey, Walter...Stechford.
- Normansell, John William...Stockport.
- Owen, John Edmund...Aberdare.
- Owen, William Hibbert...Aberdeen.
- Paris, William...Glasgow.
- Paterson, Ernest Livingstone...Woolwich.
- Paul, William...Cowdenbeath.
- Plunmtree, Percy Maln...Southport.
- Pratt, Edgar...Lancaster.
- Price, Edger Alfred...Aberdare.
- Pybus, Frank Whitsales...Kirby Fleetham.
- Rennison, Thomas James W...Kirby Stephen.
- Rigge, Harold...Lancaster.
- Roberts, Alfred Henry...Bath.
- Roberts, Henry...Burnley.
The questions set at this examination were published in the Pharmaceutical Journal for January 12, p. 596. The following is a list of the centres at which the examination was held, showing the number of candidates at each centre and the result:

Proceedings of Societies in London.

ROYAL SOCIETY.

ABOG, A NEW CONSTITUENT OF THE ATMOSPHERE.

The long-expected communication on this subject by Lord Rayleigh and Professor Ramsay at a meeting of the Royal Society, was held on the 31st ult. The theatre of the University of London had been placed at the disposal of the Society by the Senate, as its own rooms in Burlington House would have been totally inadequate to accommodate an assembly which included nearly all the most eminent chemists and physicists of the day. Lord Kelvin, the President, occupied the chair, supported by Lord Rayleigh and Professor Michael Foster, Secretaries.

The abstract which was read by Professor Ramsay, resolved itself into a clear résumé of the whole work done on the subject. In a paper read before the Society last year, "On an Anomaly Encountered in Determinations of the Density of Nitrogen Gas," Lord Rayleigh drew attention to the fact that chemically prepared nitrogen is about \( \frac{1}{4} \) per cent. lighter than "atmospheric" nitrogen. Subsequently, experiments were made with nitrogen liberated from uric acid by sodium hypobromite and from ammonium nitrite purified in the cold. These, with nitrogen prepared from nitric oxide, from nitrous oxide, and from ammonium nitrite purified at red heat, constitute the five sources of the chemically prepared nitrogen on which the authors' data are based. The mean of the five numbers, which were closely concordant, was found to be 2.2990. Now, it had been shown in the paper just referred to, that the mean number of "atmospheric" nitrogen prepared by passing air over red hot copper was 2.3103; therefore, when the presence of a new dense constituent in the atmosphere was suspected, this "atmospheric" nitrogen was passed over ignited magnesium, which absorbed the nitrogen, forming magnesium nitride. By the action of water this compound was decomposed, yielding ammonia, from which the nitrogen was liberated by calcium hypobromite and purified in the usual way. The mean number of the nitrogen so prepared was found to be 2.29918, which, as will be seen, differs but little from that of nitrogen "chemically prepared," but considerably from that of the so-called "atmospheric" nitrogen used for its preparation. This last experiment was modified by distilling off the ammonia, collecting in hydrochloric acid, decomposing the concentrated solution of ammonium chloride formed with calcium hypochlorite, and drying the evolved nitrogen.

This result confirmed the first—that nitrogen prepared from magnesium nitride, obtained by passing "atmospheric" nitrogen over hot red hot magnesium, has the density of "chemical" nitrogen directly prepared. It was also shown that the ammonia produced from the magnesium nitride was identical with ordinary ammonia by converting it into ammonium chloride, and titrating with silver nitrate, which had been standardised with pure ammonium chloride.

From these experiments it was concluded that red hot magnesium withdraws... from "atmospheric"
nitrogen no other substance than nitrogen capable of forming a basic compound with hydrogen. When the discrepancy in the weights of "atmospheric" and "chemical" nitrogen was first noticed, various attempts were made to account for it by the presence of various impurities. The most probable was hydrogen. However, the fact that the intentional introduction of hydrogen into the heavier gas, which was afterwards treated as before, had no effect upon its weight, negated this idea, and it was finally proved that the difference could not be due to the presence of any impurity. Again, it was obviously possible either that nitrogen existed partly in an allotropic, or partly in a dissociated form; that is to say, a difference existing in its atomic and molecular arrangements by which the comparative lightness of "chemical" nitrogen would be due to dissociation, and the heaviness of atmospheric nitrogen to allotropic condensation.

However, the fact that both kinds of gases when submitted to the action of the electric discharge retained their weights unaltered, was convincing enough that the source of the discrepancy had to be sought elsewhere. The theory of dissociated atoms was still further negated by storing a sample of chemically prepared nitrogen for eight months, when the density showed no change whatever. Had this theory been tenable, one would have expected the dissociated atoms to disappear, thus exhibiting an analogy to ozone.

It therefore appeared certain that one or other of the gases must be a mixture. But it was difficult to see how the one of chemical origin could answer this description, except upon the hypothesis of dissociation which had been already negated. Therefore, the most probable explanation was to admit the presence of another ingredient in air, from which oxygen, moisture, and carbonic anhydride had already been removed. The method universally adopted by which it is decided whether a gas is pure or a mixture, is that of diffusion. That experiment was not conducted at this stage of the research, as it would have been of no assistance in isolating the new constituent of the atmosphere. At a later period, however, when results were obtained sufficiently conclusive of themselves to prove the presence of a previously unknown gas in the air, Graham's method was utilized to prove that the diffusive power of "atmospheric" nitrogen indicated the presence of a gas appreciably heavier than pure nitrogen.

The identity of "phillogistated air" with the constituent of nitric acid is due to Cavendish, who distinctly raised, and to a certain extent solved, with the crudest of apparatus, the question now brought forward after the lapse of a hundred and ten years (see p. 664). The existence of a second ingredient in the so-called "atmospheric" nitrogen being admitted, various substances were experimented with in order to decide upon the best absorbent of the nitrogen gas and allow of the examination of the residue. Of the substances tried, magnesium in the form of ribbon was found to be the most effective, the process being to pass "atmospheric" nitrogen over magnesium heated in a hard glass tube until all the metal was converted into nitride. In the earliest attempts made to isolate the gas by sparking air with oxygen in the presence of alkali, a Rahmoff coil of medium size actuated by five Grove's cells was used. When the mixed gases were in the right proportions, the rate of absorption was about 80 C.C. per hour. Finally, a residue of gas remained which no longer disappeared by combination with oxygen and removal by alkali, and constituted about 1/120th of the air used. That this was not nitrogen was argued from its resistance to the prolonged action of the spark. After repeating this experiment several times and with various modifications, it was concluded that the amount of residue was in direct proportion to the amount of air operated upon. A comparison of the spectrum with the airspectrum also proved that at any rate the residue was not nitrogen.

In the course of early experiments on the withdrawal of nitrogen from air by means of red hot magnesium, a preliminary experiment gave the residue of density, 14.88, when the gas was not passed over, but simply allowed to remain in contact with the magnesium. However, by passing "atmospheric" nitrogen backwards and forwards over the metal, at the same time adopting other precautions, the density was increased to 19.09. On sparking this product mixed with oxygen for several hours, the volume was still further decreased, the density of the remaining gas being calculated for 200. After giving full details of the proof of the presence of argon in air by means of analysis, Professor Ramsay proceeded to describe the negative experiments which showed that argon was not derived from chemically prepared nitrogen. Considerable difficulty had been experienced in conducting these quantitative negative experiments, and a long time had been required to bring them to a successful conclusion. In several cases argon was found, but only in a fractional amount of that occurring in atmospheric nitrogen, and its presence was mainly accounted for by leakage of apparatus or contamination. To prepare argon on the large scale, air is freed from oxygen by means of red-hot copper, the residue is then passed from a gas-holder through a combustion tube containing copper, which is heated in a furnace to remove any trace of oxygen. The rising gas is then dried and enters a second combustion tube containing magnesium turnings heated to redness. The process is repeated until all the nitrogen is absorbed by the magnesium, and the unabsobered gas is free from any possible contamination of oxygen, hydrogen, or hydrocarbons.

The density of argon, prepared by means of oxygen and magnesium respectively, has been found to be 19.7 and 20.38. Determinations of the solubility in water of argon prepared by sparking gave 9.84 volumes per 100 of water at 15°. The solubility of the gas prepared by means of magnesium was found to be 4.05 volumes per 100 at 15°. The gas is, therefore, about two and a half times as soluble as nitrogen, and possesses approximately the same solubility as oxygen. All attempts to induce this new constituent to combine have as yet failed. It is, in fact, on account of its absolute chemical inertia that the authors have given
it the name of argon. In conclusion, discussing the probable nature of this gas, or mixture of gases, the authors consider that they are justified in concluding that argon is present in the atmosphere. They are inclined to the belief that argon is a monatomic element: for if it were di- or poly-atomic the atoms would acquire no relative motion, even of rotation, a conclusion exceedingly improbable. An important property of argon is the ratio of its specific heat at constant temperature and constant volume, which has been found to be 1.66, and it is claimed that this figure does not allow of the existence of chemical or other kinetic energy, except such as may suffice for the translatory motion of the molecules. The density has been already mentioned as approximately 20-0, and assuming that the molecule is monatomic the atomic weight would be 40. It seems to be probable that argon may prove to be elementary, but whether one element or a mixture of two is yet uncertain.

Mr. W. Crookes, after congratulating the authors upon their valuable paper, described the spectroscopic peculiarities of argon. His paper was illustrated by photographs thrown on the screen and a map in which the spectral lines of sunlight and other sources were accurately figured.

From these it seems that argon gives two distinct spectra—according to the strength of current employed—and therein resembles nitrogen, but the two are readily distinguished, as one nitrogen spectrum shows bands and the other lines, whilst the argon spectrum consists of sharp lines only at a different position upon the scale. Mr. Crookes' remarks were in favour of the hypothesis that argon is a mixture, and in this respect were opposed to those expressed in the next paper.

This was a contribution from Dr. K. Olzewski, Professor of Chemistry in the University of Cracow, whose investigation on the "Liquefaction and Solidification of Argon" caused him to be opposed to the idea that argon is a mixture, since it has a definite melting point, a definite boiling point, and a definite critical temperature and pressure, and because, on compressing the gas in presence of its liquid, pressure remains sensibly constant until all the gas is condensed to liquid. Professor Olzewski reports that by lowering the temperature of the oxygen by slow exhaustion to 190°, argon froze to a crystalline mass resembling ice. On lowering the temperature still further it became white and opaque, and melted when the temperature was raised, the melting point being determined as a mean of four experiments as 189°6. He also finds that the density of liquid argon at the boiling point (-187°) is much higher than that of oxygen.

Dr. Armstrong, President of the Chemical Society, in the course of his remarks quite admitted the conclusiveness of the evidence for the existence of the new body. At the same time he was of opinion that a good deal of speculation had been indulged in as to its properties, especially as to its inertia, which did not seem compatible with its strong points of resemblance to nitrogen.

Professor Röcker, President of the Physical Society added his congratulations to those of Dr. Armstrong and pointed out the important issues that arise from argon having this particular ratio of specific heat.

After Professor Roberts Austen had made some remarks, Lord Rayleigh made some general observations on the nature of research, and the discussion was concluded by Lord Kelvin.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting was held on Thursday, January 31, when the evening was devoted to the reading of short papers by members. The following papers were read:

NOTES ON FILTRATION.

BY H. G. GUYER.

The paper dealt with filtration, objects and methods, filtering media and means of expediting filtration. The object of filtration is either to obtain a clear liquid, free from solid matter, or to collect a precipitate. Great skill is required in filtration on the large scale, in order to save time and to avoid loss of material by evaporation. Various media are used, such as flannel, calico-muslin, paper, etc., calico and muslin being chiefly used for straining, which is an operation preparatory to filtration in which the liquid is obtained free from the greater portion of suspended solid. Flannel bags are largely used for filtering large quantities of material, and considerable skill is required in order to obtain the filtrate clear and bright, and yet to ensure rapid filtration. Filter papers vary very much; but all should be tested for extractive matter, such as iron salts, etc., and this is best done by extraction with acid and alkali and subsequent neutralisation. The chief method of expediting filtration is by use of a vessel, into which the filtrate can be received, and which is rendered vacuous by vacuum pump. The methods of adding powders, such as silica, pumice, charcoal, etc., to preparations requiring filtration were also described.

WHAT SHOULD BE DISPENSED FOR AQ. MENTH. ?

BY MR. HMAIP.

This question was again raised for discussion, and the author expressed the opinion that aq. menth. pfp. should be dispensed, seeing that it is more universally used than aq. menth. virid.

In the discussion which followed, the opinion was generally expressed that the dispenser should be guided by the custom in the particular locality, in which the prescription was dispensed, and that to save all ambiguity it was desirable that aq. menth. should be a synonym of aq. menth. pfp. in the new pharmacopoeia.

RELATIVE MERITS OF DIFFERENT PILL COATINGS.

BY MR. DYSON.

The author had examined the merits of the following pill coatings with especial regard to their relative solubility. The method employed was to coat a pill containing ferrous sulphate with the par-
ticular coating in question, and then place it in a beaker containing a dilute solution of potassium ferrocyanide at the temperature of the stomach. The following results were obtained:

With silver leaf coating there was a distinct precipitate after twenty minutes.

With sandarco or tolu varnish the coating cracked at certain places, and at those points, after twenty-five minutes, a precipitate was visible, but only at these points. The pearl coating first cracked and separated, but it was apparent that there was a varnish present underneath the pearl coating, and the precipitate appeared after one and a half hour.

With gelatin coating the gelatin at once began to swell, and a distinct precipitate was observed in one minute. The author therefore advocates the use of gelatin coating, since it is easily applied, is transparent, and dissolves readily. The pills can be coated by the pharmacist himself, and the gelatin solution is best made by adding 3 parts of water to 1 part of best gelatin, and melting in a water bath.

The pearl-coated pills are probably the worst, since they are often dried before coating, and the coating also takes a long time to dissolve.

SOME DISPENSING DIFFICULTIES.

BY G. MON.

In dispensing the following prescriptions, certain interactions occurred which are described under each prescription. All the prescriptions occurred in actual practice.

B Tr. ferri perch. .................................. 3/4
Acid carbol. ........................................ ½
Acid sulphuric ....................................... ½
Aquam ad ........................................... ½
M. ft. garg.

The dark colour formed on mixing becomes discharged after a short time.

B Pot. chlor. ........................................ gr. v.
Calo. hypophosph. ................................ gr. v.
Magnes. sulph. ..................................... gr. x
Ferri sulph. ......................................... gr. ½
Liq. strychn. ....................................... ml.
Aq. ad .............................................. ½
M. ft. mist.

Insoluble calcium sulphate and iron hypophosphite are formed.

B Soda salicyl. ..................................... gr. x
Am. carb. .......................................... gr. ½
Sp. eth. nit. ......................................... ml.
Sp. chlorof. ........................................ ml.
Aq. ad .............................................. ½
M. ft. mist.

B Pot. brom. ........................................ gr. x
Antiphon ........................................... gr. v.
Tr. ferri perch. ................................... ml.
Sp. chlorof. ........................................ ml.
Aq. ad .............................................. ½
M. ft. mist.

B Codein ........................................... gr. ½
Add. phosph. dil. ................................ qts.
Add. hydrocyan. dil. .............................. m.x
Tr. iod. ........................................... m.x
Aquam ad ........................................... ½iv.
M. ft. mist.

The brick-red precipitate of alkaloid is dissolved on adding the acid. hydrocyan. dil.

B Liq. hydraz. perch. .............................. 3/4
Liq. arsenicals .................................... m.v.
Sp. chlorof. ......................................... m.v.
Aquam ad ........................................... 3/4
M. ft. mist.

The alkaline solution of arsenic precipitated the mercury salt. The acid solution was substituted, when a clear solution resulted.

B Hydrarg. subchlor. ............................... 3/4
Liq. calc. saoch .................................... ½
M. ft. lotta.

To be added to each pint of water.

This was necessary because the patient required a large quantity of lotion. The decomposition appeared to be the same as in the case of lot. hydrarg. subchlorid, although after some weeks the dark precipitate began to get lighter in colour.

Now while it may be possible to use the saccharated solution of lime for the above, it becomes quite another thing when it is added in a diluted form to mercuric chloride, because in this case, providing the lime solution is added gradually, only the red oxide is precipitated, whereas if the solution of lime be added to the finely powdered mercuric chloride quickly, little, if any, precipitate results; in fact, should a solution of the mercury salt in glycerin and water (grs. v. to 3l.) be used, and then the diluted liq. calc. saoch. added all at once, the solution remains quite clear, but will deposit a blackish precipitate after a few hours.

Provincial Transactions.

PLYMOUTH, DEVONPORT, STONEHOUSE, AND DISTRICT CHEMISTS' ASSOCIATION.

JUNIOR SECTION.

A meeting of the above was held at the Foresters' Hall, Octagon, on Thursday, January 31, among those present being Mr. C. J. Park (President), in the chair, R. F. Roper (Senior Section), Dewdney, Buckner, Barber, Venn, Darre, and O. H. Westcott (hon. sec.). A letter was read from Mr. E. H. Newman resigning his position as junior chairman on leaving the town. The resignat was accepted with regret. The following paper was then read:-

PHARMACY—REAL AND IDEAL.

BY HENRY A. HODGE.

"Comparisons are odious," and especially are they so to those who advocate and promote a system or state of affairs which, when weighed in the balances, is found wanting, and therefore must take the lower level. Pharmacy as a "profession" in this country has advanced in no little degree with regard to its educational requirements of those who would enter its fraternal circle and the commendable process of "shift-
ing" still goes on with great activity at the head-quarters in Bloomsbury Square. On the other hand, pharmacy as a "trade" seems to offer a paradox, in that it appears to be slowly but surely advancing—backwards. Not that the pharmacist is slowly sinking to a lower footing in the hivc of Society, or that those who are just entering the business have less advantages than their predecessors, but one by one the very principles and processes which constitute the practice of pharmacy, fall, perforce of circumstances, to find a place in the every-day routine of a chemist's business. To illustrate; taking the preparations of the British Pharmacopela, the guide and standard of the pharmacist wherever he may be, how many of the tinctures, liquors, infusions, extracts, etc., therein enumerated, are actually made by the individual business man? How much of his time is occupied in real practical pharmacy? Circumstances have altered cases truly, and the outcome of progress has been the dividing of real pharmacy between the "manufacturer" and the "retailer."

With the bulk of the pharmacists of to-day the question is entirely, from a trade point of view, "How best to keep pace with the times?" Time is money, for the most devoted student and highest educationist must acknowledge that even the "mere druggist of this world" is useful at times. Concentration is the order of the day. Space being precious, the need for a more compact method of stocking drugs is supplied by concentrating liquids into one-eighth and one-twentieth of their bulk, and compressing solids into tablet form. The old-fashioned bolus is replaced by the elegant little sugar-coated granule, and the most fastidious of the public may have no bitter pill to swallow. Could a few of our ancestors drop into one of our most modern pharmacists, what a metamorphosis they would find! To see the manipulator at the dispensing counter, the dispatch and style in which the mixture is put up, the coating of pills with sugar, gelatin, keratin, or varnish, the powders being put into cachets and so on, it would be difficult for them to realise that they were really in the modern edition of their ancient dispensaries.

The pharmacy of yesterday, to-day, and to-morrow may differ widely in detail, but the fundamental principles of its study are the same throughout. The methods of our forefathers may appear crude to our latter-day ideas, but they were adapted to and sufficient for the times in which they lived. So the pharmacist of our own time, alied by the journals of pharmacy, which week by week bring before him suggestions and experiences of his fellow-workers, keeps abreast of the times and adapts himself to the circumstances. On pharmacy in the "real"—as it is, most of us will agree that it might be better; in the "ideal"—as it should be, opinions will greatly differ.

One individual's ideal state of pharmacy may be quite contrary to that of another, and the ways and means adopted by one class of pharmacists to reach the "ideal" might be utterly distasteful to the other. All agree, no doubt, that the chemist is and should be the legitimate dispenser, but on the methods to be used to make it so fast accomplished chemists themselves seem to disagree. We hear of suggestions for the better consolidation of those engaged in pharmacy in which the ideal is prominent, but the ways to get at it are diverse. Of course combination of forces exerts the greater pressure, so in matters of pharmaceutical legislation a united effort on the part of the parent Society and kindred local societies would bring about greater success to pharmacy as a whole.

Practical pharmacy is the main study in the training of the chemist, to which the studies of chemistry, botany, and materia mediae come as useful adjuncts in enabling him to become a thoroughly all-round man. It is important to enforce upon the minds of the junior members the necessity of obtaining and retaining all the advantages for study during their apprenticeship, as they will all help them on in their career.

To the man in business "Pharmacy up-to-date" is no burlesque, it is stern reality. Competition is a universal feature, and to him pharmacy as it really is must be far from ideal. The "possibilities" of pharmacy are unlimited, but the "probabilities" of the same are somewhat veiled until we know what steps our leaders are taking towards the betterment of our class as traders. As a profession—a class of men who undergo examination—monopoly should be the reward of the pharmacist, not in the mere selling of poisons only, but in everything pertaining to the importation and preparation of drugs and their compounds. It may seem early to dream of monopolies, but impracticality is not out of the question where ideas coincide. It follows, then, that to reach an "ideal," of whatever kind it may be, ambition combined with effort is essential in the individual. Combination of individuals will form an association, and combination of associations will form a body both influential and representative. When the pharmacists of our country realise to the fullest extent that "union is strength" then that point will be reached in the position of pharmacy where the "real" merges into the "ideal."

Mr. C. J. Park said that in reviewing pharmacy as it existed in this country, it pointed much towards the survival of the fittest, seeing that the conditions required of those who enter it were not so stringent as in other countries; he did not think a good all-round man would ever find much difficulty in making some headway in his profession, and advised the junior members to persevere in their studies.

Mr. R. F. Roper, whilst agreeing in the main with the views expressed in the paper, could not see how any form of monopoly in the drug trade could be brought about to suit all concerned, the progress of pharmacy depended greatly on the rising pharmacists's apprentices and assistants of to-day, who were under much better conditions than those of former years.

Messrs. Westcott and Dewdney, in the course of their remarks, endorsed the remarks of the previous speakers.

On the motion of Mr. Westcott, seconded by Mr. Dewdney, a vote of thanks was unanimously passed, also to the Chairman for presiding.
Scottish Transactions.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

At the meeting on Wednesday, January 30, Mr. Alex. Sutherland, President, in the chair, a debate took place on the question—

SHOULD THE SCOPE OF THE PRELIMINARY EXAMINATION BE EXTENDED?

Mr. George Coull in opening the affirmative side said, on May 11, 1841, at the introductory pharmaceutical meeting of the Pharmaceutical Society of Great Britain, a paper was read by Jacob Bell in which he contrasts the position occupied by those who follow pharmacy in Great Britain with that held in other countries, and especially in France and Germany. He shows us up our deficiencies, and emphasizes the need for education in comparison with the men of scientific acquirements and education who practise pharmacy in France. The paper is explanatory of the objects the founders had in establishing the Pharmaceutical Society. The first one is union of the chemists into one recognized independent body; second, protection of their general interests; and third, the advancement of the art and science of pharmacy. They consider (to use his own words) that their own interest, as well the safety and welfare of the public, demand that no person shall become an apprentice in their business who has not had the advantage of an adequate fundamental education. This shows how these men, the fathers and grandfathers of pharmacy as it is now, saw the necessity for an adequate preliminary education of all those who contemplated pharmacy as a means of livelihood. This subject of education permeates all their actions and sayings and the actions of their successors in the Council even to the present day, besides being the theme of numerous editorial notes, of many addresses by men whose names will live in pharmacy for ever, and of much correspondence in the Pharmaceutical Journal from that day to this.

The Royal Charter of Incorporation was granted on February 18, 1843, to William Allen and divers others of Her Majesty's loving subjects for the purpose (among others) of promoting an uniform system of education of those who should practise pharmacy. The Act of 1852 was a purely educational statute. The Act of 1868 is sometimes contemptuously termed a "mere poisons Act," but it inaugurated a new pharmaceutical era in making it compulsory for those assuming the title of chemist or druggist to have competent skill and knowledge and qualification; that is, to be adequately educated. The question now to be considered is what constitutes an adequate fundamental education, and this question must be treated as a progressive one. It is obvious that what was thought to be sufficient over fifty years ago will not satisfy our requirements now; more especially as the examination was then a voluntary one, and it was, therefore, deemed inadvisable to make it too difficult in order that candidates might not be deterred from coming forward. From an editorial note on the classical examination in the Journal for January 1, 1848, we are informed that the Council do not think it expedient to raise the standard too high in the first examination. The examination then comprised a knowledge of Latin, sufficient to translate the Pharmacopoeia and physicians' prescriptions, and of the simple rules of arithmetic. The editor hopes that it will in course of time be found practicable and expedient to extend the course of study required for this examination, feeling persuaded that an elementary acquaintance with physics and mathematics is of great importance, and that some knowledge of the modern languages might be added with advantage. He concludes, however, that this will be subject for consideration when the examination is enforced by Act of Parliament. Again, in an article, August 1, 1867, the opinion is repeated that a knowledge of the above subjects would be advantageous, and, furthermore, parents are advised not to limit the academical instruction of their sons to what is absolutely required for this examination.

From this it is evident that at that time even as at the present there were those whose only thought was how little do I require to know in order to pass. In October, 1888, when I had the honour of addressing this Association from the presidential chair, I advocated reorganization of the Preliminary examination, increased stringency, and its scope widened by the introduction of elementary mathematics and French or German, giving reasons for adding these. I need scarcely recall to your minds the vigorous article by Mr. J. E. Saul, a member of the London examining board, in the Journal for April 4, 1891. The language of Mr. Saul was rather strong at times, and while agreeing with him in most of his statements, I think he was rather hard on the minor candidates. This article was productive of a vast amount of correspondence on the subject, and elicited an almost complete consensus of opinion that the time had now arrived when the scope of the Preliminary should be widened. Following came the discussion on the Preliminary examination by the London Chemists' Assistants' Association, when a motion was unanimously carried that the Preliminary should offer a better test of a youth's general education and ability. And yet we stand almost where we were when the suggestion of increasing the scope of the examination was made in January, 1848, and it was stated it would be subject for consideration when the examination was enforced by Act of Parliament. This examination was enforced by Act of Parliament in 1868, and the opportunity of making it a real test of a fairly good education was allowed to slip, a thing, I opine, which would not have occurred had Jacob Bell been living at that time. The new regulations altered the Latin required to the first book of 'Cesar's Gallic War,' and added a knowledge of English, and of vulgar and decimal fractions. Lately we have had 'an addition to the schedule of numeration, the metric system, percentages, stocks, etc., with the first book of Virgil's "Enoid" as an option to Cesar, and—there we are.

I have tried, and succeeded very imperfectly, to give
a historical sketch of the Preliminary examination, and
to show that it has been the idea from the beginning
to insist upon a certain educational standard, and to
gradually raise that standard. Why that was not
done in 1888 is a great mystery. I think I once
heard that there was something in the Charter or the
Acts that prevents this being done. While acquainted
with the subtle meaning; that can sometimes be
extracted from Acts of Parliament, I yet think the
matter is plain enough. Charter, line 93: "...
and such associates, apprentices, and students shall
first be duly examined in such manner as the Council
of said Society shall deem proper." Pharmacy Act,
1892, section ii., gives the Council power to alter the
bye-laws after certain formalities have been gone
through. Section viii. mentions the subjects of
examinations, "Latin language, botany, materia
medica, and pharmaceutical and general chemistry,
and such other subjects as may from time to time be
determined by the bye-laws." As to the necessity for
increasing the scope of the examination, and the
advantages that would accrue from so doing, what
can I add to what has been already said?

Speaking generally, a more rigid test of the capa-
bilities of candidates for admission to our ranks
would exclude some whose retiral from pharmacy
would be advantageous to all. It is by education
alone that we can raise the status of the trade,
and with that will come naturally increased
remuneration for our services. Speaking specifically,
I can only repeat what I said before when I advocated
the same cause I am addressing you about now.
That nowadays even an elementary knowledge of
mathematics is of great advantage to the student of
chemistry, while for the proper understanding of
physics it is absolutely essential. In order to read
intelligently a text-book on modern chemistry one
must know a great many things that were not deemed
necessary not so long ago, while a knowledge of
German, though elementary, is of great importance.
As to the precise form the extended examination
should take, it is time to offer opinions when we see
the matter properly under weigh. I think a recom-
mendation for the student in Scotland to obtain the
leaving certificates of the Scottish Education Depart-
ment would be attended with good results. Another
idea is to vary the Latin authors prescribed (giving
due notice, of course), so that a youth may not get
up the whole book, and repeat any portion—parrot-
like—when he gets a cue—a thing that has actually
been done. I can only say that, ceteris paribus, it is
the educated man who succeeds best in this vale of
tears. I leave the case here, and I hope, for the
honour of the Association, that my views will prevail.

Mr. J. McIntosh Cameron, in moving the nega-
tive, said: The subject under discussion is one which
merits the serious consideration of every one of us.
The question is full of difficulties, and is one on which
we should not pass our final opinion till we have
thoroughly exhausted the arguments to be brought
forward on both sides. Mr. Coull has shown us
the advantages. It will be my endeavour to
point out the evident disadvantages which would
arise from an extension of the Preliminary
subjects. One of the greatest disadvantages
would be that an ordinary youth having left school at
the age of 15 or 16 would either waste a year of his
apprenticeship in getting up the additional subjects,
or it would be necessary for him to undergo a special
course of study for at least a twelvemonth to prepare
those subjects, a knowledge of which it is almost im-
possible to obtain in an ordinary school. Take the
suggested subjects. What time is there between the
age of 9 and 15 for anyone to obtain a fundamental
knowledge of these subjects? The result of their in-
roduction would be that at the very commencement
of his career he would undergo a process of cramming
in acquiring a smattering knowledge of at least two
subjects—a lack of the fundamental principles of
which would place him on an artificial foundation.

He would then commence his training for a profes-
sion with his mind full of a lot of notthings and a small
amount of somethings, which might in after life prove
a curse rather than a blessing. What chemist of the
old school can look upon his assistants of the present
day without regret when he contemplates the process
of cramming to be undergone for the all-important
Minor? Then why add to the Preliminary subjects
which would necessitate the introduction of this pro-
cess at the opening of each apprentice's career? Do
the advantages counterbalance the disadvantages?
One of the principal advantages is supposed to be
that a more highly educated class of men would
be introduced into the so-called profession. What
would be the result? They would probably be too
high and mighty for their ordinary duties. A special
staff would have to be engaged for such duties as the
taking down of shutters, cleaning windows, sweeping
floors, swabbing greasy ointment slabs, dusting bottles,
and a thousand and one little items which are con-
idered to be all important in the education of the
apprentice of to-day. The apprentice of the future
would be displaying always a maximum of shirt-
front and a minimum of that knowledge essential
in the carrying on of an ordinary pharmacy.

We then would be looked upon as the old standard
of chemist is looked upon now by some—a hindrance
to the profession; when, truth to tell, they are really
the ornaments thereof. Speaking generally, the
ornaments of our profession are the men of the old
school, whose whole time was spent in obtaining a
thorough acquaintance with practical pharmacy,
rather than hunting for outside knowledge which
would be of no material benefit to them in after life.
Let us do away, once and for all, with that cant and
humbug on the subject of higher education which
has of late years been so conspicuous. Let us have
more time taken up with the consideration of how
rather to fit present pharmacy to the requirements
of the pharmacist of to-day, rather than straining so
far into the future and trying to fit the pharmacist
of the third and fourth generation for that pharma-
cutical position which may never be attained.
What does the future offer to those men possessed
of a standard of education fitting them for a class in
society which the remuneration from their profession
will not permit them to move in? They would become discontented with their lot and seek the earliest opportunity of entering an allied profession which would offer higher remuneration and greater social advantages.

Let us consider the results of the examination as it stands at present. If it is the desire of those anxious for a higher code to debar by this means an excess of successful candidates, surely the present percentage of failures quite justifies my argument that the examination is severe enough. Which of us, on entering for the Preliminary, did not consider it, at that time, a sufficient test of our ability? If there must be a change, rather let it be in the time appointed for the passing of the examination. Make it compulsory for everyone, before starting apprenticeship, to pass the Preliminary, and thus allow him to devote all the spare moments of his apprenticeship to obtaining a gradual knowledge of the subjects necessary for the Minor. To keep the student in touch with his studies and give him a stimulus for future work introduce an Intermediate examination, so that the present gap between the Preliminary and the Minor would be done away with. The days of apprenticeship would thus become one continuous course of study rather than a period of little or no study followed by a terrific grind extending from three to an indefinite number of months, according to the luck of the candidate. It is a thorough intimacy with pharmacy which we as pharmacists require, not a general knowledge of a variety of subjects which are doubtless very useful in their own way. Therefore we should seek to regulate the examinations so that youths immediately on entering their apprenticeship may be compelled to seek after a knowledge of those subjects which are the all essentials in the building up of a modern pharmacist.

Mr. Swanson seconded the affirmative and Mr. Thwaites seconded the negative, and the debate was continued by Messrs. Burns, Hill, Macpherson, McEwan, and Sutherland.

After the replies by Messrs. Cameron and Coull, a vote was taken, and the affirmative was carried by a majority of two to one.

A circular from the Federation of Associations' Committee was remitted to the Committee with powers.

Mr. McEwan gave an interesting sketch of the history of the Association prize scheme, and the following note was then read.

**Correspondence.**

**"TABLOIDS" AND THE NEW BRITISH PHARMACOPEIA.**

Sir,—In your contemporary, the British Medical Journal of February 2, a writer on pharmacology uses laudatory language in regard to compressed "tabloids," and says "it would be useful to have something of this sort" "in the new edition of the Pharmacopeia" (see Pharm. Journ., p. 664). Can the writer be aware that the word "tabloid" is a registered trade-mark of a firm of Americans, who can claim neither originality nor superior excellence for the manufacture of medicines compressed into this form, English houses having been makers of these for nearly fifty years to my knowledge? Is the English word "tablet" or its Latin equivalent not expressive enough, that we need to have a word coined which is a hybrid of Latin and Greek? The use of even the word "tablet" was challenged by them. The way in which prescribers are led by the nose by the advertisements of monopolists, who assume to themselves the right to influence the mode of medical prescribing, is intolerable, as we cannot dispense a compressed tablet of antipyrine if it has been prescribed as a "tabloid" without interfering with the trade-marks of two foreign firms, if we give anything but that of the manufacture of one and the compressing of the other. To give an instance, in my pharmacy-to-day (Feb. 4) a prescription ordering "tabloids"—not in stock—of a drug wanted immediately, was presented. On sending post-haste to the firm referred to above, I learnt such tabloids had never been prepared by them; another maker's "tablets" had, therefore, to be supplied. This instance is not solitary.

From a writer of such eminence as Dr. Lander Brunton we might not expect less tendency to quackery, or rather monopoly, and a closer adherence to our mother tongue than is shown in using the word "tabloid" in place of "tablet." We have "antifebrin," "phae-

**CHROMIC ACID AND COCAINE HYDROCHLORATE.**

**By JAMES MCBAIN.**

Recently the following prescription was handed to me to be dispensed.

Acid. Chromic..........................grs. iv.
Cocaine Hydrochlorate..................grs. vii.
Aqua.....................................3fl.
Solve.

The acid was dissolved in 3 fl. of water, and the cocaine hydrochlorate in the other 3 fl. of water. On mixing the two solutions the whole became thick from the separation of an orange-yellow precipitate. The action seems similar to that of the U.S. Phar-
tended for the use of the medical man. "It is a work
issued by the General Medical Council as a standard and
guide to the members of the medical profession, and only
secondarily to chemists and pharmacists. This is seen by
the fact that the latter have no direct voice in the prepara-
tion of the Pharmacopoeia, and have only been called in to
give advice when required." Is this the fact? If the
medical man, instead of having his prescription dispensed
by the chemist, supplies his own medicines, he may pre-
pare them as he likes. It is only when he writes a pre-
scription that the necessity of a pharmacopoeia becomes
apparent. If we accept the position of being the physi-
cian's cook we may claim at least to be the joint compilers
of the cookery book. If he selects the dishes we must,
if we have to follow his orders, direct how they are to
be prepared. It is time that pharmacists in Great Britain
struck for that conjoint right which they possess in most
civilised countries.

THE MANCHESTER MEETING.

Sir,—I shall be pleased if you will allow me space to
draw more attention to an important resolution passed at
our Manchester meeting on the 23rd ult. than is likely to
have been attracted thereto by your necessarily condensed
report. The resolution dealt with the question of un-
restricted equality on the Council of the Pharmaceutical
Society, and was intended as an indication to the Council
that the proposal of last year respecting the number of
chemist and druggist members on the Council was not
approved by the subscribers to the Society. This is, I
believe, the first time that this point has been raised in a
large and representative meeting of the trade, and the
most pleasing feature in connection therewith, and one
deserving of special note, is that the mover, seconder, and
supporter of the resolution are all Pharmaceutical Coun-
cillors, the last having been a student contemporary with
Mr. Carteigne. That this resolution was carried without
a dissentient voice is a fact that should weigh with our
esteemed members of the Council in future attempts at
legislation. I would add that with one solitary exception
every Pharmaceutical Councillor with whom I have dis-
cussed this question during the past month has approved
most heartily of the suggestion to remove this one single
obstacle to a united Society, a Society having one qualifica-
tion and no disabilities.

Manchester.

HARRY KEMP.

Sir,—I had hoped some able pen than mine would
have been wielded in support of the President's remarks
at Manchester, and am much surprised and disappointed
at the small amount of criticism and controversy his
address has evoked. It may be that we are all so much in
accord with Mr. Carteigne's contentions that we do not
feel called upon to say anything pro or con. But if that
be the case his trouble in giving his address would
amount to little more than expression of per-
sonal opinion, and the chief object of its delivery
would remain unachieved. I gather from the Presi-
dent's remarks that we are in search of some method of
improving the status of chemists as a class, and of making
it possible for them to earn a living by the exercise of
their legitimate calling; that these desirable ends can
only be arrived at by approaching Parliament, and
that to do this successfully we must be
present and present a bold front. How is this union to
be brought about? I, personally, think there ought
to be sufficient esprit de corps in every man who
voluntarily adopts a calling to induce him (without
any consideration of 2 s. d.) to rally round its standard
and do his level best for the general weal. Unfortunately
our calling seems to be an exception to this salutary
proposition. The majority are either loungers and stand
aloof, or they are in more or less active opposition. Minor
men are said to grumble because they are not admitted to
membership, and the existing chemist and druggist mem-
bers because they are not sufficiently represented on the
Council. As a pharmaceutical member I say admit to
membership all who pass the qualifying examination, and
remove the restriction on the number of chemist and
Druggist members eligible to sit on the Council if this will
satisfy the outsiders and induce them to join the Society. I don't think the pharmaceu-
tical chemist members would object to this, provided
it was the means of attaining the desired result.
A few might think it would destroy the distinction in the
eyes of the public between the Major and Minor qualifica-
tions; perhaps to some extent it would, but, for myself,
I am willing to risk that. I think it a great pity that
Major men have not cultivated the title pharmacist in
preference to that of pharmaceutical chemist; it is one of
the titles distinctly reserved by the Pharmacy Act to
Major examiners, and its use since 1868 would long before
this have educated the public to recognise two classes of
dispenser of medicines, the pharmacist and the chemist;
instead of which, we usually find the former title used in
its generic, instead of its specific sense, and applied to the
whole craft, instead of a comparatively small section of it.
There are many other important points in the President's
admirable address one might dilate upon; but these
questions of membership and representation on the
Council seem to be the fundamental difficulties. With
these out of the way we may get into line, so to speak,
become unanimous in the conviction that we want some-
thing, arrange later on what that something shall be,
and then work unitedly to make that something an accom-
plished fact.

St. Mary's Pharmacy, Manchester.

CHAS. SWINK.

A SUGGESTION.

Sir,—It has often struck me that the public are not
sufficiently reminded of the "why and the wherefore" of
our position as an exclusive trade. May I throw out as
a useful suggestion that chemists should keep conspicuously
in their windows and elsewhere the preamble of the
Pharmacy Act, 1868—"Whereas it is expedient for the
safety of the public, &c.," appending thereto a copy of their
certificate of examination, which is of much too modest a
character. If some enterprising printer took up the
idea there is money in it.

209, Caledonian Road, N.

E. WARRELL.

DIASTATIC OR DIASTATIC?

Sir,—As you are aware the expressions "diastatic" and
"diastatic" are both in use among chemists, the latter
being the more common. I have been kindly granted a
conjoint opinion of the Professor of Chemistry and the
Professor of Greek in Edinburgh University, that the
more correct form is "diastatic."

Edinburgh.

THE HISTOLOG OF IPECACUANHA.
BY HENRY G. GREENISH.
Professor of Materia Medica to the Pharmaceutical Society of Great Britain.

The ipecacuanha plant, *Cephaelis ipecacuanha*, is described by Martius as producing a perennial root, simple or divided into a few divergent branches, which enter the earth obliquely, are winding, 4 to 6 inches long, rarely longer, and mostly narrowed a little at base and apex. The stem exhibits a disposition to bend downwards and creep along the ground; here and there it is nodose, and at the nodes it produces roots.

This description agrees well with the appearance of the drug received from Brazil, and from a consideration of the habit of the plant and the manner in which the root is collected it is evident that we must expect to find in the commercial drug, which should consist of root: alone, portions of both prostrate and erect stem. As a matter of fact, almost every bag of Brazilian ipecacuanha that reaches the London market contains both prostrate and erect stem mixed with the root in varying proportion; it is even by no means uncommon to see bags of the drug consisting almost entirely of stem.

The root is usually dark brown in colour; occasionally it is brick red; in this case the colour is partially removable by washing, and is due partly at least to adhering particles of red earth. When well developed, the root is characterised by marked transverse annulations; under a lens the transverse section exhibits a slender wood surrounded by a thick mealy or horny cortex.

The erect stem is paler in colour, uniform in thickness, and longitudinally striated. Its section shows a comparatively thin cortex and a wood enclosing an oval or rounded pith. The prostrate stem is frequently intermediate in appearance between root and erect stem; the colour is sometimes dark and the surface rough.

In the very young root the stele is diarch or, according to Holfert,† sometimes triarch. The pericycle consists of a single layer of cells, and is separated by a well-marked endodermis from the extra-steral parenchyma, which usually numbers about four rows of cells. The primary phloems groups are small, and the primary xylem consists of tracheides. All the cells of the central conjunctive tissue subsequently develop also into tracheides, so that in mature roots there is no trace of pith. During the further growth of the root a phellogen forms in the pericycle (Fig. I.), which now appears to consist of two rows of cells, and the whole of the extra-steral parenchyma, including the endodermis which has then collapsed, is thrown off. A rapid development of parenchymatous tissue now takes place, largely by division of the parenchymatous cells of the medullary rays in the secondary bark. The tissue so produced may remain comparatively limited in extent, in which case the root retains its fibrous character. Such fibres may be found in the ipecacuanha of commerce, although being easily broken, the majority of them are probably lost; occasionally they form a considerable portion of the drug. On the other hand, the parenchyma may increase considerably in thickness, and this it frequently does locally, at points where rootlets have been attached (Fig. II.). In this manner a swelling is developed on one side of the root. Usually a number of such swellings are produced in close proximity to one another and occupying the same position as the rootlets; in a diarch root, therefore, on alternate sides of the root or in a triarch root in the form of a spiral. In this way the annulations of the root are eventually produced. Careful examination of a well-developed root will show that these annulations are not strictly discs, but

Vol. LIV. (Third Series, Vol. XXV.), No. 1236.
rather slightly elliptical wedges, the wood occupying approximately the position of the axis of the thinner ends of the wedges; the latter almost invariably alternate with the thicker ends in which traces of the rootlets can be found.

If a transverse section of a well-developed root be examined under the microscope the whole of the cortical parenchyma and many cells in the wood will be found to be filled with starch grains. These can be removed by clearing and the following structure can then be observed:—

Fig. III. Ipecacuanha; Brazilian Root. Trans. Sect. (Tachirob).

The tegumentary tissue (Fig. III., c.) consists of several rows of thin flattened cork cells containing a brown granular substance to which the normal dark brown colour of the root is due. The cork cells of the red root contain a similar colouring matter. Viewed from the surface they exhibit an irregular polygonal outline (Fig., IX. p.); they are produced by a single phellogen layer formed from the cells of the pericycle.

The parenchymatous tissue that follows the cork consists of rounded or polygonal, frequently axially, elongated cells with few intercellular spaces; here and there a cell filled with raphides is conspicuous; mucilage, in which such raphides are often embedded, I have not been able to detect. This parenchyma is developed partly from the pericycle, partly from the medullary rays of the secondary bark into which tissue it passes without any visible line of demarcation. The phloem forms wedge-shaped groups of cells, the apex of the wedge directed of course, towards the cork. They are not conspicuous, but may be detected by the small size of the cells and the irregularity of their walls. In the phloem parenchyma raphides are frequently found.

The wood consists entirely of small elements. The medullary rays are not conspicuous, all the cells of the wood showing about the same radial elongation. If, however, a fresh section is stained with iodine, more or less regular radiating lines of cells containing starch can be distinguished; these lines of cells undoubtedly correspond to, and perform the function of, medullary rays. A tangential section shows that the cells of which they are composed are much axially elongated, and not strikingly different from the rest of the tissue.

After separation by one of the usual methods into its constituent elements, the wood, including the medullary rays, will be found to consist principally of two forms of cells (Fig. V.). On the one hand tracheids (tr.) with more or less pointed ends, and consequently oblique transverse walls, in which a perforation is commonly to be seen. In these tracheids the pores are usually oval, right, or sometimes left, oblique and areolated (compare

Fig. V.—Ipecacuanha; Elements of Brazilian Root-wood. x160.

Fig. VIII., tr.). Such perforated tracheides are not confined to this drug; they have been recently figured and described by Boodle and Wordsell* from Casuarina, Carpinus, and Gnetum.

On the other hand, fibrous cells (f, c.) are frequent; in these the pores, which are usually right oblique, are less numerous and not areolated. Practically they differ from ordinary wood fibres only in their pores and in the fact that they contain starch, and hence are not solely mechanical in their function. True wood fibres have left oblique pores and never con-

* 'Comparative Anatomy of the Casuarine.' (Annals of Botany, viii., 281.)
tain starch. In addition to these two cell forms, true wood parenchyma cells (par.) can be found, as well as intermediate forms, such as Sanio’s “ersatzfasernzellen,” which Professor Vines translates “intermediate cells (int. c.).” True vessels are invariably absent.

A tangential section shows that the tracheides are the only elements free from starch; the medullary rays are seldom well defined, the elements of which they consist usually exhibiting strong axial elongation (compare Fig. VIII).

The starch grains (Fig. VI.) are mostly compound.

![Fig. VI.—Ipecacuanha; Starch of Brazilian Root. x500.](image)

The component grains number commonly from two to four, occasionally as many as eight or even more, and are most frequently mullet shaped, with one or two flat surfaces. The hilum is usually a distinct point; or its position may be indicated by a simple or triangular cleft. In length they occasionally reach 0.0125 Mm., but never exceed 0.015 Mm. These figures are derived from measurements of grains in several roots of each of about twenty samples. Swollen grains are frequently to be found, and indicate the use of artificial heat, probably in drying the root.

The alkaloids are said to reside principally in the parenchymatous tissue near the phloem. On account of the starch with which the tissues are loaded, its detection microscopically is very difficult. The two precipitants usually employed, potassium bichromate and picric acid, have yielded in my hands unsatisfactory results. I have endeavoured to turn to account the only definite colour-reaction of emetine, that with chlorine, by allowing the gas evolved from a crystal of potassium chlorate and strong hydrochloric acid to impinge on a moist section. By this means emetine solutions are coloured brown or deep yellow. Sections of ipecacuanha root treated in this way are cleared of starch by the hydrochloric acid vapour and the parenchymatous cells, especially those near the cork assume a decided yellow or yellowish-brown colour. The wood is comparatively slightly effected. From results with dried roots, however, no con-

![Fig. VII.—Ipecacuanha; Brazilian Stem. Trans. Sect. x350.](image)

orclusions can be drawn as to the localisation of the alkaloid in the fresh root, since it has been repeatedly shown that during the process of drying alkaloids escape from the cells in which they were originally contained and pass into the neighbouring tissue.

Having dealt at some length with the histological features of Brazilian ipecacuanha root, the anatomy of the erect stem may be discussed more briefly.

In this the cork, which is similar in structure to that of the root, is of subepidermal, not pericyclic origin. The extra-stelar parenchyma (Fig. VII., par.), which is very narrow in comparison with the secondary bark of the root, frequently contains
starch grains and raphides. The endodermis is distinct; a portion of the middle lamella running axially and tangentially around each cell is lignified, and hence can easily be rendered conspicuous by the usual lignin reagent (Fig. VII, end.). Within the endodermis the cells of the pericycle very frequently thicken and lignify, and thus form a more or less complete ring of sclerenchymatous cells one, two, or even three deep (Fig. VII, scl.). In transverse section they appear more or less tangentially elongated; sometimes, indeed, the tangential axis is longer than either of the others. They are provided with unbranched pores and vary in diameter from '01 to '12 Mm., commonly ranging from '03 to '06 Mm. (Fig. VII, scl.). In the erect stem this ring is usually well developed; in the prostrate stem it is much reduced, whilst from the root it is completely absent. Hence intermediate cells (int. c.) are also present; all these resemble the corresponding elements in the root wood. Further, the sclerenchymatous cells (scl.) from the pericycle are very characteristic and easily found. The cells of the pith (p.) are usually nearly cubic, and distinguished from cells of the extrastellar parenchyma (and of the cortical parenchyma of the root) by their distinct pores and by the lignin reaction, which they yield with any lignin reagent. Lastly, here and there can be found a portion of a spiral vessel (sp.) an element present in the protostele, but not in the secondary wood.

Hence it will be seen that there are three elements which characterise the stem and distinguish it from the root, viz., the sclerenchymatous cells of the pericycle, the lignified cells of the pith and the spiral vessels of the primary xylem.

Cultivated ipecacuanha from Singapore occasionally finds its way into the London market. It is identical in physical character, in structure, and in the size of the starch grains with the Brazilian root, and is practically indistinguishable from it. It appears to be unusually free from stem and to show well-developed annulations.

A small parcel of Madras cultivated root offered for sale in January was remarkable for its strong annulations and its freedom from stem; no striking difference from Brazilian root could be detected. During the last few years an ipecacuanha has been imported in large quantities from Carthagen, the botanical source of which is unknown. It differs from the Brazilian by its size, which is usually greater, by the annulations, which are usually less marked—in fact, they are often represented by little more than raised ridges—and by the steams, which are commonly thicker. It is the "ipecacuanha annelé majeur" of Guibourt ("gris blanc" of Merat), who says in 1820 that it occurs...

Fig. IX.—Ipecacuanha; Elements of Brazilian stem. *Scl.* scl. cells; *p.* pith cells; *p,'* cork cells. X160.

It is possible to find portions of stem with a tolerably complete ring at one end and no sclerenchymatous cells at all at the other.

The phloem and the conjunctive parenchyma is far less developed in the stem than it is in the root, but the wood presents much the same appearance. In the centre, however, is a fairly large pith, the cells of which have slightly thickened, porous lignified walls (Fig. IX., p.).

As an accurate knowledge of the distinguishing anatomical details of the stem is important, it is necessary to separate this also into its component elements (Fig. X.). Both tracheides (tr.) and fibrous cells (f.c.) will be found, the latter in this case predominating. Wood-parenchyma (par.) and inter...
only very sparingly. I have examined an original specimen of Gubourt's preserved in our museum and find it to be undoubted Carthagena root.

This Carthagena ipecacuana occurs both in red and brown or dark greyish-brown varieties, a difference due mainly to the soil. In structure, both of root (Fig. XI.) and stem (Fig. XII.), it is practically identical with the Brazilian drug. In the stem, which is usually erect, seldom prostrate, the same ring of sclerenchymatous cells can be found, and the extent to which this is developed may vary in one and the same piece.

![Fig. XI.—Ipecacuana; Elements of Carthagena Root-wood. x160.](image)

The most characteristic feature that can be found is the size of the starch grains (Fig. XIII.). The largest of the single grains frequently reaches 017 to 022 Mm., but rarely exceeds the latter figure. They vary, however, in size in roots from one and the same bale, and even in a root and its branch. They are usually largest and least compound in roots with a thick cortex, smallest and most compound in the stem. These particulars are also derived from the examination of roots from at least twenty different bales. As regards size, therefore, the starch grains are liable to variation, and some caution is necessary in employing such a character for the purposes of diagnosis. The same is true of the elements of which the wood of Brazilian or Carthagena ipecacuana is composed.

It has been suggested by Professor Hartwich* that the Carthagena ipecacuana which reaches the market is derived from two distinct plants. This opinion he bases on the difference in colour, in the number of component grains in the compound starch grains, in the presence or absence or sclerenchymatous cells, and in the greater or less distinctness of the medullary rays. I have endeavoured to show that the red colour, at least in the samples I have examined, is partly due to adhering soil, and finds a parallel in the Brazilian root; that the compound starch grains vary in the number of their component grains in one and the same root; that sclerenchymatous cells may similarly be present in or absent from different points in one and the same stem. Certainly the medullary rays in some roots do appear to be more distinct than in others,

![Fig. XII.—Ipecacuana; Elements of Carthagena Stem. x160.](image)

but I do not think that there is sufficient evidence to support Professor Hartwich's opinion.

From the foregoing details it will be gathered that as distinctive characters of ipecacuana root, either Brazilian or Carthagena, by which it may be recognised as such in the form of powder, there may be mentioned (a) the form and size of the starch grains; (b) the absence of vessels, presence of perforated tracheides; (c) the acicular raphides; to these may be added (d) the emetic reaction with chloroform.

The stem may in either case be distinguished from the root (in powder) by (a) the presence of sclerenchymatous cells; (b) of lignified cells of the pith; (c) of spiral vessels.

Lastly, Carthagena ipecacuana may in most cases be distinguished from Brazilian by the larger

---

size attained by its starch grains. In this respect it must be carefully remembered that Carthagenan roots with small starch grains occur, which are practically indistinguishable when powdered from Brazilian roots with large grains. Possibly during the investigation now in progress, of the quality of the powdered ipecacuanha supplied to retail pharmacists by wholesale druggists, other characters may be brought to light that will facilitate the identification of these two varieties of ipecacuanha.

THE CHEMISTRY OF IPECAUANA.

BY DR. S. H. PAUL AND A. J. COWNLEY.

In some papers published conjointly by us previously, in the Pharmaceutical Journal, it has been shown that the descriptions generally given of the alkaloid, to which the medicinal action of ipecacuanha is attributed, are for the most part erroneous. It is stated that this constituent of the drug as hitherto obtained, is chemically an individual substance; but the accounts given of its physical characters are remarkably discordant. We have, on the contrary, shown that ipecacuanha resembles cinchona bark—a product of the same natural order—in containing at least two alkaloids, and probably other alkaloids in smaller proportions.

Of the two alkaloids which we have isolated and examined, one is uncrystallisable but capable of forming salts which are crystallisable, though for the most part very freely soluble. This base is readily soluble in ether, alcohol, or chloroform, very sparingly soluble in water or petroleum spirit, and insoluble in solutions of caustic alkali. We have retained for it the name of emetine.

The other alkaloid—cephasine—is crystallisable, less soluble in ether than emetine, but freely soluble in alcohol or chloroform, much more soluble than emetine in hot petroleum spirit, and ready soluble in solutions of caustic alkali.

By these characters the difference between the two alkaloids is very distinctly marked. There are also differences in their melting points—emetine melting at 68°C, cephasine at 102°C—and in their percentage composition, as is shown by the following comparison:

<table>
<thead>
<tr>
<th></th>
<th>Emetine</th>
<th>Cephaseine</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbon</td>
<td>72:01</td>
<td>71:28</td>
</tr>
<tr>
<td>Hydrogen</td>
<td>8:86</td>
<td>8:69</td>
</tr>
<tr>
<td>Nitrogen</td>
<td>5:75</td>
<td>6:24</td>
</tr>
<tr>
<td>Oxygen</td>
<td>13:38</td>
<td>13:79</td>
</tr>
</tbody>
</table>

These figures give as their most simple expression the following formulae:

- Emetine: \( \text{C}_16\text{H}_22\text{N}_4 \text{O}_6 = 248 \)
- Cephaseine: \( \text{C}_16\text{H}_24\text{N}_4\text{O}_6 = 234 \)

Analysis of the neutral hydrochloride salts has shown that the quantities corresponding to these formulæ are respectively equivalent to one molecule of hydrochloric acid.

The very marked peculiarity, common to both alkaloids, of forming crystalline salts more readily in the presence of excess of acid than when neutral solutions are slowly evaporated, led at first to the erroneous conclusion that neutral cephasine salts were uncrystallisable and that the crystallisable salts of both emetine and cephasine were acid salts. It has since been ascertained that cephasine hydrochloride can be obtained in well-defined prismatic crystals when a slightly acidified salt is slowly evaporated on the plate, and that this salt contains an equal molecular proportion of alkaloid and acid.

In the case of emetine the influence of an excess of acid in determining the formation of a crystalline salt is still more marked. On adding a drop of moderately strong hydrochloric acid to a particle of emetine, a mass of acicular crystals is at once formed.

Both emetine and cephasine are very sensitive to the influence of light. Though perfectly colourless when pure and in a free state, they rapidly acquire a yellow colour when exposed to sunlight.

Solutions of the alkaloids in alcohol, chloroform, benzene, or ether, also become coloured on exposure to light with formation of a reddish-coloured deposit. The salts of both alkaloids on the contrary do not appear to undergo similar alteration; but in a pure state remain perfectly colourless when exposed to light.

Since the publication of the last paper on ipecacuanha a third alkaloid—the probable existence of which has already been indicated—has been isolated in small quantity. It exists in the drug in very small amount relatively to emetine and cephasine, and it differs from those alkaloids in being very sparingly soluble in ether. This alkaloid is soluble in alkaline liquids, and it remains in the ammoniacal liquor from which emetine and cephasine have been extracted by shaking with ether. It was extracted from that liquor by shaking with chloroform. The quantity obtained as yet was too small to admit of complete examination, but the physical characters of this alkaloid distinguish it in a very definite manner. It is a crystallisable substance obtainable by slow evaporation of an ether solution in well-defined transparent prisms of a pale lemon-yellow colour. It melts at about 138°C, neutralises acids, and apparently has a much higher molecular weight than emetine or cephasine. It dissolves readily in alcohol or chloroform. Its solutions becoming dark coloured on exposure to light and depositing a dark brown substance.

The failure of most previous observers to arrive at correct conclusions in regard to the alkaloids of

* Ph. J., iii., 61, iv., iii., 873.
Ipecacuanha presents some collateral features of interest, inasmuch as it shows how largely the results of such investigation may be determined by accidental circumstances. The extraction of ipecacuanha with chloroform in the presence of caustic potash adopted by Ledfort, naturally furnished a product consisting of a mixture of all the alkaloids, and in the absence of any ascertained distinction between them their separation was impossible. Hence the formula assigned to emetine by that observer, on the basis of Dumas' analysis, was inaccurate. In the subsequent investigation by Lefort and Wurtz the result arrived at was defective for the same reasons, although the mixed alkaloids were then obtained in a condition of greater freedom from impurity by extracting the drug with ether in presence of lime.

The result obtained by Podwysosiitzki by using ferric chloride to get rid of the tannic constituent was vitiated by the use of petroleum spirit for extracting the drug. While the product thus obtained was an indefinite mixture of cephaline and emetine as a consequence of the action of that solvent on both the alkaloids, probably the greater part of the emetine was not extracted at all by the petroleum spirit.

In the investigation by Kunz petroleum spirit was also used for extraction with a similar result, as shown by the fact that the alkaloid obtained is described as (partially) soluble in caustic alkalis. The formula deduced from analysis by Kunz was, therefore, necessarily incorrect, as the material operated upon by him must have been of a mixed nature. The experiments made by Kunz for the purpose of ascertaining the constitution of emetine were also for the same reason fallacious, and, therefore, no importance can be assigned to the conclusions arrived at by him in 1867, or to those which he has more recently put forward on the same basis.

The investigation of the alkaloid of ipecacuanha by Glénard was, however, more fortunate in its result. That circumstance was due to the care taken in obtaining the alkaloid in the state of a crystallised neutral hydrochloride, after extracting it from the drug by treatment with lime and ether. As a natural consequence of this mode of operating, the cephaline was eliminated, and emetine was isolated in a pure condition, as shown by the results of Glénard's analyses, which correspond very closely with our own. Indications of the existence of another alkaloid were observed by Glénard, but they were not followed up by him.

Glénard's observations appear to have received little notice, however, and in most chemical works the formula assigned to emetine by Kunz has been adopted as the most satisfactory. That view must now be abandoned since the data already published in our previous papers prove that the substance to which it relates could not have possessed chemical individuality.

It is satisfactory in connection with this point to be able to refer to results obtained by Messrs. E. Merck, of Darmstadt, in following up our observations on the alkaloids of ipecacuanha. In the Bericht, for 1884, recently published by that firm, it is stated that on repetition of our work in their manufactury, our descriptions have been fully confirmed, while the statements of Dr. Kunz-Krause could not be adopted. Following the indications given in the papers already published by us, Messrs. E. Merck now manufacture emetine and cephaline and their salts, and announce that they are prepared to supply these substances for medicinal use. We understand that they are already receiving orders from England.

The reputed value of ipecacuanha in the treatment of acute dysentery gives a great importance to this drug, but its emetic action has been found an inconvenient objection. Acting upon the assumption that the emetic action is due to the alkaloid, it has been proposed to make use of the drug from which that constituent has been removed. The successful results obtained by some medical men in India with de-emetine ipecacuanha suggest the possibility that the value of the drug as a remedy for dysentery may be due to some other treatment than the alkaloid.

Some attempt was therefore made to isolate and study another constituent of ipecacuanha which has been described by Willigk, under the name of ipecacuanhic acid, as analogous to tannic acid and having a composition represented by the formula C_{6}H_{8}O_{5}. Following on the lines of Willigk's process an alcoholic extract of ipecacuanha was mixed with basic lead acetate until no further precipitate was formed. The lead precipitate, collected and thoroughly washed, with strong alcohol, was treated with weak sulphuric acid not quite sufficient to convert the whole of the lead into sulphate, and the clear alcoholic liquid was evaporated to dryness. In that way a reddish-brown amorphous material was obtained amounting to about 22 per cent. of the drug, and corresponding to Willigk's description,—very soluble in water, or alcohol, of bitter taste, and giving a green coloration with ferric salts, but not precipitated by gelatin. It was found to have no emetic action in doses of 4 or 5 grains. After boiling with acid it reduces Feuling's solution. The product so obtained was, however, a crude material, and probably of a mixed character. By treatment with absolute alcohol it was almost entirely dissolved, leaving about 5 per cent. of residue. The solution mixed with dry ether, gave a white precipitate amounting approximately to 20 per cent., which darkened on exposure, and presented some resemblance to saponin, and after boiling with acid it reduced Feuling's solution. On evaporating the ether alcohol solution a residue was obtained amounting to about 60 per cent., which was soluble in water, and gave a dark green colour with ferric chloride. The water solution did not froth on shaking, but after boiling with acid it reduced Feuling's solution.

These characters point to the probability that Willigk's ipecacuanhic acid was not a definite substance, but a mixture, and further examination will be requisite for ascertaining its true chemical nature. That appears to be of importance as regards the medicinal action of ipecacuanha, since it is stated on good authority that the utility of the drug in the treatment of dysentery is augmented by the removal of the alkaloids.

The two alkaloids, emetine and cephaline, are contained in the ipecacuanha of New Grenada, as well as in that of Brazil, the only difference in this respect being the larger relative proportion of cephaline in the New Grenada drug. So far, therefore, as the medicinal effects of the drug are due to these alkaloids jointly, there would appear to be but little
difference between Brazilian ipecacuanha and that of New Grenada, so that the latter might without disadvantage be made official in the Pharmacopoeia. The medicinal properties of ipecacuanha are due to the alkaloids emetine and cephaline, it may be inferred from the characters of these substances that in making galenical preparations of the drug, a process which would ensure their conversion into salts would be preferable to one furnishing a product in which the alkaloids were in a free state and liable to alteration under the influence of light. In that respect the acetic acid extract used in the preparation of the official B.P. wine would seem to be well adapted. A down process with solutions of the salts do not appear to undergo alteration when heated, unless it be that the acetic extract is too mixed a product containing some constituent which helps to destroy or remove the alkaloids. Mr. John C. Umney's observations on the loss of alkaloid in ipecacuanha wine to the extent of one-fifth seems to point in that direction. But now that the alkaloids or their salts are obtainable in a pure state, a very excellent ipecacuanha wine, suitable for administration as an expectorant, can be made by dissolving half a grain of emetine hydrochloride in four ounces of sherry.

**WAX AND ITS IMPURITIES.**

B. S. PROCTOR.

In view of the repeated instances in which tradesmen have suffered annoyance, if nothing worse, from its being found that wax which they have sold has not been pure beeswax, it is well that pharmacists should again have their attention drawn to the facility with which they can put a sample to two of the most important tests.

A sample of beeswax, white or yellow, should sink if thrown into B.P. solution of ammonia, 959 sp. gr. When first immersed it is liable to have air bubbles attached, which bring it to the surface, but if rubbed with the solution and immersed again it will if pure go to the bottom.

The B.P. gives the sp. gr. of wax as 960 to 970. In Watts' Dictionary of Chemistry, 1894, the gravity is given as 965. In the Pharmaceutical Journal, March, 1887, Dietrich says it should be 962 to 964. My own observation, from clear honeycomb and beeswax, agrees with the latter figures, and I think the Pharmacopoeia allows more latitude than necessary. If it be desired to take the exact gravity of a specimen which does not correspond closely with that of the solution of ammonia it is very conveniently done by adding a little water, or a little strong solution of ammonia (880) till the gravity of the solution and the fragment coincide, and then determine that of the liquor with the specific gravity bottle.

Of course a correct density does not prove that the wax is pure, but it is fair evidence that there is no large admixture of paraffin wax, the most probable adulterant.

The next most important characteristic is the tough plasticity which a fragment shows with the warmth of the hand, it is best observed by rolling 2 or 3 grains like a pill between finger and thumb, then with strong pressure drawing the finger from the tip of the thumb towards the joint. Under this treatment, good wax should curl up towards the tip of the moving finger, while adulterated samples usually spread like salve on the ball of the thumb, or crumble with the friction.

I do not bring these forward now as novelties, for I have elsewhere drawn attention to them, nor as superseding more elaborate examination, but simply as having value at the moment from the readiness with which they can be applied.

**NOTES ON RECENT SCIENTIFIC INVESTIGATION.**

**SALTS OF ARSENIOUS ACID.**—Up to the present time only a few of the salts of ortho-arsenous acid As(OH)₃ have been obtained, and the existence of some of these has been doubted. The whole question has, however, been reinvestigated by Stavenhagen, who has prepared several new salts and confirmed some of the previous observations. Only the ortho-arsenites of calcium, magnesium, zinc, and silver were known, and possibly the Lead, chromium, and nickel salts. The salts of the alkali metals have been prepared in a similar manner to that of the potassium salt, which is as follows:—"Alcoholic potasb and arsenic acid are mixed and boiled for a long time. After evaporation the syrup mass is crystallised from absolute alcohol, when potassium ortho-arsenite, K₃AsO₃, is obtained in needle-shaped crystals. The sodium and ammonium salts are non-crystalline, and are obtained in a similar manner. By means of the potassium salt, the corresponding salts of the other metals as strontium, barium, cadmium, tin, gold, platinum, etc., were able to be isolated and examined. The general method of preparation was as follows:—The salt of the metal, generally the chlorides, was mixed with an aqueso or alcohollosolution of potassium ortho-arsenite, when the arsenite of the metal is precipitated and separated by filtration and purified if necessary by suitable methods. The complete series of metallic orthoarsenites were obtained with the exception of those of chromium, nickel, and possibly copper.

The salts of meta-arsenous acid, H₂AsO₃, and of pyroarsenous acid, H₂As₂O₅, were also examined and prepared, but this work was chiefly a confirmation of that of previous workers (Journ. fur prakt. Chem., Li. 1)."
when there is a great excess of nickel, some cobalt remains in solution. Ammonium salts should be absent, as well as metals precipitable by sulphuretted hydrogen in acid solutions or by ammonia in the presence of ammonium chloride. As a general rule in the separation of the metals, the filtered liquid separated after adding sulphuretted hydrogen, and ammonia should be treated with fresh ammonium sulphhydrate, avoiding excess. The precipitate must then be treated with very dilute hydrochloric acid, and boiled. The black residue should be dissolved in a little aqua regia, and the solution tested for nickel and cobalt as already described, after evaporating off the greater part of the excess of acid. Care must be taken when but little cobalt is present to avoid too great dilution of the liquid, or the metal may remain in solution and colour it brown, in the absence of nickel. The addition of a large excess of soda, however, will completely precipitate the cobalt and leave the liquid colourless.

CHEMISTRY OF PHOTOGRAPHY.—Seyewetz and Chisandand have endeavoured to explain the results ensuing from the decomposition of sodium hyposulphite in fixing photographic images (Bulletin de la Société chimique de Paris [5], xiii., 11).

When an excess of acid reacts in the cold upon the hyposulphite, the reaction is as follows:—

\[ \text{Na}_2\text{S}_2\text{O}_3 + 2\text{HM} = 2\text{NaM} + \text{NaHSO}_3 + \text{SO}_2 + \text{H}_2\text{O} + \text{S} \]

It may be that hyposulphurous acid is first liberated and immediately decomposed, thus:—

\[ \text{H}_2\text{SO}_3 = \text{SO}_2 + \text{H}_2\text{O} + \text{S} \]

If the hyposulphite be in excess, sulphuretted hydrogen, sulphurous acid, and a sulphate are formed. This may be explained by supposing that the nascent hyposulphurous acid, in the presence of the excess of hyposulphite, gives rise to a very unstable acid sodium hyposulphite, which ultimately decomposes into sodium sulphate, sulphuretted hydrogen, sulphurous acid, and sulphur, thus:—

1. \[ \text{Na}_2\text{S}_2\text{O}_3 + 2\text{HM} = 2\text{NaM} + \text{NaHSO}_3 \]
2. \[ 2\text{NaHSO}_3 = \text{Na}_2\text{SO}_4 + \text{H}_2\text{S} + \text{SO}_2 + \text{S} \]

or, representing the reaction in one equation, thus:—

\[ 2\text{NaHSO}_3 + 2\text{HM} = 2\text{NaM} + \text{Na}_2\text{SO}_4 + \text{H}_2\text{S} + \text{SO}_2 + \text{S} \]

The sulphurous acid and sulphuretted hydrogen, in turn, are capable of decomposing sodium hyposulphite, besides reacting upon each other. In the case of an excess of sulphurous acid, the equation representing the result is as follows:—

\[ \text{Na}_2\text{S}_2\text{O}_3 + \text{H}_2\text{SO}_3 = 2\text{NaHSO}_3 + \text{S} \]

With but excess of the hyposulphite it would be—

\[ 2\text{Na}_2\text{S}_2\text{O}_3 + \text{H}_2\text{SO}_3 + \text{H}_2\text{O} = \text{H}_2\text{S} + \text{Na}_2\text{SO}_4 + 2\text{NaHSO}_3 + \text{S} \]

Sulphuretted hydrogen gradually decomposes sodium hyposulphite into sodium bisulphite and acid sulphide, and sulphur, thus:—

\[ \text{Na}_2\text{S}_2\text{O}_3 + \text{H}_2\text{S} = \text{NaHSO}_3 + \text{Na}_2\text{SO}_4 + \text{S} \]

whilst with sulphurous acid it forms pentathionite acid, which in turn reacts with sodium hyposulphite to form sodium pentathionate and hyposulphurous acid, the latter again forming, with excess of hyposulphite, an acid hyposulphite which splits up as already described, thus:—

1. \[ 5\text{H}_2\text{S} + 3\text{SO}_2 = 4\text{H}_2\text{O} + \text{H}_2\text{S}_2\text{O}_3 + \text{S} \]
2. \[ 2\text{Na}_2\text{S}_2\text{O}_3 + \text{H}_2\text{S}_2\text{O}_3 = \text{Na}_2\text{S}_2\text{O}_4 + 2\text{NaHSO}_3 \]
3. \[ 2\text{NaHSO}_3 = \text{H}_2\text{S} + \text{SO}_2 + \text{Na}_2\text{SO}_4 + \text{S} \]

Thus, the action of an acid, in the cold, upon an excess of hyposulphite gives rise to sulphurous acid sulphuretted hydrogen, a salt of sodium corresponding to the acid employed, sodium sulphate, and sulphur, whilst secondary reactions result in the formation of sodium bisulphite, pentathionate, and acid sulphide.

The action of aluminium sulphate upon an excess of sodium hyposulphite on boiling, results as follows:—

\[ 3\text{Na}_2\text{S}_2\text{O}_3 + \text{Al}_2(\text{SO}_4)_3 = \text{Al}_2\text{O}_3 + 3\text{Na}_2\text{SO}_4 + 3\text{SO}_2 + \text{S}_2 \]

In the cold, however, sodium sulphate and aluminium hyposulphite are first formed:—

\[ 3\text{Na}_2\text{S}_2\text{O}_3 + \text{Al}_2(\text{SO}_4)_3 = 3\text{Na}_2\text{SO}_4 + \text{Al}_2(\text{S}_2\text{O}_3)_3 \]

but the latter, being very unstable, splits up into aluminium sulphate and sulphuretted hydrogen:—

\[ \text{Al}_2(\text{S}_2\text{O}_3)_3 + 3\text{H}_2\text{O} = 3\text{H}_2\text{S} + \text{Al}_2(\text{SO}_4)_3 \]

and the sulphuretted hydrogen, in the presence of excess of sodium hyposulphite, converts the latter into sodium bisulphite and acid sulphide, whilst sulphur is liberated thus:—

\[ \text{Na}_2\text{S}_2\text{O}_3 + \text{H}_2\text{S} = \text{NaHSO}_3 + \text{Na}_2\text{SO}_4 + \text{S} \]

All the reactions take place very slowly, and this explain why fixing agents containing hyposulphite and alum deposit sulphur during a length of time, although they retain their property of hardening gelatin on account of the gradual regeneration of aluminium sulphate, and the formation of aluminium bisulphite which acts in a similar manner.

With regard to the action of sodium sulphite and bisulphite when added to prevent the decomposition of hyposulphite by acids or alum, the bisulphite has no such effect in the case of acids, though the sulphite is converted in bisulphite, and thus slightly retards the decomposition. The effect is more marked in the case of alum, however, the bisulphite or sulphite reacting with it to form the corresponding salt of aluminium, without affecting the hyposulphite present, thus:—

\[ 6\text{NaHSO}_3 + \text{Al}_2(\text{SO}_4)_3 = \text{Al}_2(\text{SO}_4)_2\cdot 3\text{Na}_2\text{SO}_4 \]

The aluminium bisulphite does not act upon sodium hyposulphite, which is only altered by free sulphuric acid, and as the action of alum upon hyposulphite is very slow, it is not surprising that the presence of sodium bisulphite or sulphite considerably retards the decomposition. If the proportions employed be one of alum to twenty of hyposulphite, the weight of commercial bisulphite (40 per cent.) employed should be one-fifth that of the alum. But with a mixture of fifteen grammes of hyposulphite and sixty grammes of alum, the bisulphite should not exceed one-hundredth part the weight of the latter.

ACTION OF AMMONIA ON ACETO-ACTIC ESTER.—The exact constitution of the product obtained by the action of ammonia on aceto-acetic ester has been investigated by Thomas Mamert (Bull., xiii., 68). Two views have been held as to the constitution of this compound: (i.) that it is an imido-derivative, i.e., contains the group \(-\text{NH} \), replacing the carbonyl oxygen in aceto-acetic ester; (ii.) that it is an amido-compound, and thus contains the group \(-\text{NH}_2 \), which replaces carbonyl oxygen, and results in an ethylene linking in the molecule. The formula are—

1. \( \text{CH}_2\text{C} = \text{CH}_2\text{C} = \text{O} \text{Et} \) or (ii.) \( \text{CH}_2\text{C} = \text{CH} = \text{CO} \text{Et} \)

\[ \text{NH} \]

\[ \text{NH}_2 \]
From this it will be seen that according to (ii.) the substance is the ethyl ester of amido-crotoneic acid. This view is supported by Collie and by the physical properties as determined by Bruhl and Perkin. The work of Thomas Mamert also supports this view. The ethyl ester of the β-chlorocrotoneic acid was prepared by the action of phosphorous pentachloride on ethyl acetoacetate. By this method, however, a mixture of the two stereoisomeric β-chlorocrotoneic esters was obtained, so the mixture was boiled with a little iodine, when the whole was converted into the β-chloroanilicrtonic ester, the formula of which is

\[ \text{CH}_2\text{C}-\text{Cl} \]
\[ \text{H}_2\text{C}-\text{CO}_2\text{Et} \]

This salt was now treated with alcoholic ammonia, when a product, identical with that formed by the action of ammonia on ethyl acetoacetate, was obtained. The body thus obtained must contain NH₃ in place of Cl, and on reference to the formula it will be seen to be identical with the formula (ii.) given above. The product of the action of ammonia on ethyl acetoacetate, the corresponding ester is therefore of amido-crotoneic acid.

**Calcium Carbide.**—The decomposition of this compound by water into pure lime and acetylene has recently been made use of on a large scale in the United States for the formation of acetylene gas, which it is proposed to use as an enricher of coal gas. As calcium carbide at present can only be prepared by means of the electric furnace, the electricians are pleased to find that they can be of service to the manufacturers of coal gas, and consequently the subject is one which is of considerable interest at the present time. According to Moissan, calcium carbide can be obtained by placing an intimate mixture of 120 grammes of calcium oxide from marble and 70 grammes of carbon from sugar in the crucible of the electric furnace, and subjecting it to the action of a current of 350 amperes and 70 volts for 15 or 20 minutes, when a yield of 120 to 150 grammes of the carbide is formed. Although in the United States the process adopted is somewhat different to that used by Moissan, the yield cannot be any better, seeing that, theoretically, 56 parts of lime can only produce 64 parts of the carbide, and the amount of electrical energy required must also be very similar. It is therefore evident that the process is one which will depend for its ultimate success upon the cost of production, and although the carbide is at present quoted at £4 per ton when manufactured in the States, using water-power as the source of the electrical energy, its cost of manufacture would be much higher when steam is employed. Although the high illuminating power of acetylene when burnt renders it eminently suitable for use as an illuminant, it will be seen that from its cost it is not at present likely to be adopted to any large extent in this country. Since, however, the gas may be compressed and stored in the liquid condition in cylinders, it may be found of service in this form, as a substitute for petroleum or candles in country houses and in districts where coal gas is not available, or where the conditions do not warrant the expenditure of a large amount of capital in electrical or other permanent fittings. Since from acetylene nearly the whole of the synthetic organic compounds can be readily obtained, as a source for the preparation of pure pharmaceutical preparations it may have a new future before it. The difficulty of obtaining pure materials has militated against the use of some of these newer synthetic remedies in the past, and as it is essential that organic compounds for medicinal use shall be of absolute purity, preparations derived from pure acetylene which amongst other advantages must necessarily be free from sulphur, ought to be of considerable value.

**Novel Laboratory Devices.**

**Extraction Apparatus.**—This apparatus, devised by Cha. E. Parker (Am. Drugist, xxx., 391), is intended for use in extracting alkaloids, etc., from drugs. The solvent is placed in A, and the maro in B, the two tubes E and D passing into an inverted condenser. On heating, the vaporised solvent passes into D, where it is condensed, then runs into B, and slowly percolates through the maro. Before commencing operations sufficient liquid must be placed in B to cover the lower end of the tube C, through which the saturated solvent is siphoned back to A.

**Constant Level Apparatus.**

—in the apparatus designed by J. C. Olorley, Analyst, xx., 16. for maintaining a constant level of liquid in a distillation flask, the small bulb at the lower extremity of the long thin tube inside the flask floats on the surface of the liquid. The upper end of the same tube is ground to fit into the thickened part of the larger tube surrounding it and prevents the water in the large bulb on top from flowing into the flask, except when the level of the liquid falls in the latter.
SUPPLEMENT TO THE CODEX MEDICAMENTARIUS.

The last edition of the 'Codex Medicamentarius,' or French Pharmacopoeia, was published in 1884, and there seems no immediate prospect of a reissue for some time to come, but the increase in the number of new remedies in recent years has been so great that it has been found necessary to publish a Supplement, since the need of official guidance with regard to many substances was too pressing to admit of delay until the publication of a new edition of the complete work. The Supplement has been prepared by a commission of twelve medical men and pharmacists, the president being M. Bouardel, and the vice-president, M. Plancon. It contains both additions and corrections to the Codex, the order adopted being the same as in that work, and occupies one hundred and ten pages. In the first place, the tables of densities of mixtures of alcohol and water, published in accordance with the decree of September 27, 1884, is reproduced in extenso. Then follow the lists of additions, etc., to the four parts of the Codex—crude vegetable drugs, chemicals, galenicals, and veterinary preparations. The novelties in the first list are the bark of Rhamnus purshiana (D. C.); the bark of Euonymus atropurpureus (Jacq.); Sarothamnus scoparius (Koch); the bark and leaves of Hamamelis virginica (L.); the rhizomes of Hydrophis canadensis (L.); the seeds of Sterculia acuminata (Beauv.), and of Strophanthus kombe (Oliver). The list of chemicals is remarkable for the number of synthetic and proprietary remedies included. Thus, antifebrin (actiarnide), sulphonal (acetone-diethylsulphonf), phenacetin (acet-phenetidine), ascorbin (acido anhydro-orthoureaasbenzoique), antipyrine (analgesine), benzoaphtolph (bensoate de naphthol B), aristol (diiododithymol), dermatol (gallate basique de bismuth), exalgin (methylactanilide), salipyrine (salicylate d'analgesine), and salol (salicylate de phenol), all find place. Other additions are bismuth sub-benzoate and sub-salicylate; caffeine hydrobromate and hydrochlorate; homatropine and its hydrobromate; strontium bromide, carbonate, and lactate; a combination of cannabirin and osaeus potash (cannabirin de potasse) in crystals; cocaine and its hydrochlorate; neutral quinin hydrochlorate; crystallised ergotin; eucalyptol (from Eucalyptus globulus); guaiacol; hydristine; hydristinine; menthol; a- and b-naphthol; hydrated bismuth oxide; paraldehyde; crystallised quassia; resorcin; cresol salicylate; cesserine salicylate; b-naphthol salicylate; strophanthin (from Strophanthus kombe); sparteine sulphate; tarpin (from recently rectified Bordeaux oil of turpentine); and trional (dithylethylene-methylthyl-methane). Corrections are inserted with respect to acid boric, caffeine, and sodium iodide and salicylate.

Under the heading of galenic pharmacy are found formulae for collodion with iodiform (1 in 10); purified cotton (cotton hydropaede or xylum preparatum); medicated cottons; maltino (dicateae); creosote elixir (creosote, 15 Gm., rum, 95 Gm.); soft extracts of cascaras sagrada, hamamelis, hydrastis, kola, and strophanthus (prepared by exhausting 1000 Gm. dried drug with 6000 Gm. 60 per cent. alcohol, and distilling off excess of liquid); powdered extract of euonymus (extract root bark with 60 per cent. alcohol, evaporate, and mix powdered residue with sugar of milk); medicated gauzes—acid boric, iodiform, phenol, phenol salicylate, and corrosive sublimate; strophanthin granules (containing 0-1 Mgm. each); cod liver oil with creosote (creosote, 15 Gm., oil, 95 Gm.); pancreatin; paper impregnated with mercuric and sodium chlorides, for preparing an antisepctic solution; peptone (a mixture of soluble compounds resulting from the action of peptic upon beef); sodium sulphorinicate (topique sulfuriat or iummentum sulforicinatum, prepared by acting upon castor oil, 1000 Gm., with sulphuric acid 250 Gm. washing the product with solution of sea salt, partly neutralising with soda lye, and afterwards adding potassium carbonate, 30 Gm.). Sulphorinicates of phenol, creosote, and phenol salicylate (prepared by dissolving phenol, creosote, or phenol salicylate, 30 Gm., in sodium sulphurinate, 80 Gm.), are also official; together with creosote pills (creosote 10 Gm., dried almond soap, q.s. to make 100 pills); aconitine powder (cryst. aconitine, 1 Gm., powd. sugar of milk, 96-5 Gm., carmine, 2-5 Gm.), and digitoxin, aconitine nitrate, and strophanthin powders prepared in the same way. Other galenical preparations added are cascaras sagrada powder; corrosive sublimate and tartaric acid powder (mercurio chloride, 2-5 Gm.; tartaric
acids, 10 Gm.; 5 p.c. alcoholic solution of indigo carmine, 10 drops; syrup of morcin (1 p.c.); hypodermic injections of caffeine, caffeine hydrochlorate, and basic and neutral quinine hydrochlorate; traumaticin (solutio chloroformique de guutta-percha, 10 p.c.); solution of crystallised digitalin, 1:1000; solution of hydrogen peroxide, 10 p.c.; solution of ferro-potassic tartrate (tinctura Martis); tinctures of cascara sagrada, hamamelis, hydragia, kola, and strophantus (1 to 5 of 60 p.c. alcohol in each case). Terpinol is directed to be prepared by acting on terpin, 100 Gm., with sulphuric acid, 10 Gm., mixed with water, 500 Gm., and distilling. Boric acid with vaselin (1 in 10); mercuric chloride with vaselin (0.1 Gm. to 100 Gm.); and wine of kola conclude the list. The directions for preparing wood-tar creosote (which should contain guaiacol, 20 p.c., creosol, 40 p.c., and monatomic phenols, 40 p.c.), chlorine fumigation, and granules of crystallised aconitine, digitalin, and aconitine nitrate, are corrected.

The additions to the veterinary preparations are but few. They are: Collodion with iodiform, already referred to; glycerols of starch, phenol (5 p.c.), and lead acetate (extrait de Saturne, 10 Gm., in 30 Gm.); solution of calcium lactophosphate; lotion of nicotine sulphate (10 p.c. in infusion of tobacco); β-naphthol ointment (10 p.c. with lard or vaselin); astrigent powder (poudre astringente de Knaup), consisting of ferrous sulphate, 500 Gm.; potash alum, 500 Gm.; ammonium chloride, 30 Gm.; zine sulphate, 30 Gm.; finely powdered copper oxide, 30 Gm.; diarrhoea powder for calves (tannin, 5 Gm., acid salicylic, 5 Gm.); tincture for l'antémie vermineuse, composed of tincture of male fern, 25 Gm., extract of male fern, 5 Gm.; and carbolated vaselin (5 p.c.).

THE ANTITOXIN TREATMENT OF DIPHTHERIA.

According to the Lancet of February 9 the death-rate in London from diphteria during the previous week had risen to 45 from being 34, 31, and 29 in the three weeks before that. Thus the interest in the newly adopted measures for treating the disease is by no means diminished. The reports of cases treated by antitoxin still continue to be decided in favour of the treatment. Two cases reported by Mr. Jassor to the Ophthalmological Society may be mentioned as examples of a rare form of the affection—a form in which the effect of the antitoxin had not previously been tried. One child, aged 19 months, had membrane on the inner surface of the left lower eyelid and on the uvula.

Typical bacilli were found in the membranes, and albuminuria and glandular enlargement were among the symptoms. Thus the diagnosis of the case was established beyond doubt. Three half-drachm injections of Klein's antitoxin were given, and the membrane disappeared in five days, though no local treatment beyond the application of distilled water had been employed. In the second case both eyes were affected. The membrane disappeared in four days after the injection of two half-drachm doses of the same antitoxin.

Dr. Hayward, who made the bacteriological investigation, considered that the complete and rapid disappearance of the membrane should be attributed to the antitoxin, since no other similar cases had been recorded in which the membrane had disappeared so rapidly and completely. Careful records of the after-effects of the remedy also continue to be published. Urticaria and pains in the limbs are the more common effects, and these appear to be due to the employment of excessively large doses of the serum.

Ganghofer (Prag. Med. Woch., 1896) observed that the injections seemed to diminish the amount of albuminuria. A similar observation was made in a case published by D. Macdonald, of Carlisle (Brit. Med. Journ., February 9, 1896). In one case only were serious symptoms noticed after the treatment. Dr. A. Seibert (N.Y. Med. Rec., January 19, 1896). A girl of 6½ years, on the second day of illness, was injection with 20 C.cm. of antitoxin prepared at the New York Pasteur Institute. This dose was repeated the next day. In three days she was cured of the diphtheria, but five days after her recovery she was taken ill with a rash, which was followed by high fever and swelling of the lymphatic glands. This attack subsided, and again recurred. The secondary illness lasted seven days. The time of the appearance of the rash, etc., corresponds with that observed by others after the use of antitoxin. The important conclusion to be drawn from this case is that 20 C.cm. of serum is about four times as much as should be given as a first dose.

ARGON.

In the Chemical News for February 1, Dr. G.J. Stoner suggests that argon may turn out to be a compound of one of the six missing elements that lie between hydrogen and lithium, which “seem not to have been able to enter into, or remain in, combination under the conditions that prevailed at some stage of the earth’s past history.” Of these, argon is most probably a compound of “infra-carbon,” and, assuming the atomic weight of the latter to be 2½ or 3, and that the element forms compounds similar to those of carbon, the new gas may be analogous to one of the paraffins, C3H6, C4H10, C5H20, or to some other hydro-carbon of the fatty series, or to hydro-carbons of the benzene series, or to napthalene, diphenyl, terpentine, a monatomic carbon, or other compounds, and its inertness may be such that even substitution derivatives may be very difficult to produce.
Transactions of the Pharmaceutical Society of Great Britain.

DONATIONS.

At a meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 6th inst., the Librarian and Curator presented the following report of donations to the Society's Library, Museum, and Herbarium.

To the Library.

Mr. G. Barber, Antigua, M.A. (Corresponding Member):
Agricultural Journal of the Leeward Islands, no. 2.
Supplement to the Leeward Islands Gazette, no. 32.

Mons. A. Harlant:
L'anayse du poivre de Clusius.

Mr. E. W. Giles, London:
Culpeper's Complete Herbal and English Physi- cian Enlarged.

Pharmaceutical Society of Ireland:
Calendar, 1896.

To the Museum.

Mr. T. Hanbury, F.L.S., Ventimiglia.
Fruits of the myrtle-leaved and of the Chinetto Orange, and of Hakea eucalyptoides.

Mr. H. E. Ridley, M.A., Botanic Gardens, Singapore.
Extract of Nerary bark (Casquea molucencis).

Specimen of a Polyergusus used in native medicine, and of the fruits of Strychnos spinosa.

Messrs. Lewis and Peat, London.
Specimen of sterilised Ipecacuanha.

To the Herbarium.

Professor H. H. Busby, M.D., College of Pharmacy, New York.
Fifty specimens of American medicinal plants.

Specimen of Solanum dulcisinautum and K. Thyspyi.

EVENING MEETING IN LONDON.

The third evening meeting of the session was held at 17, Bloomsbury Square, W.C., on Wednesday, the 13th inst., the chair being taken at 8 o'clock by Mr. Michael Carter, the President. Two papers were read—the "Histology of Ipecacuanha" by Professor H. Greenish, and the "Chemistry of Ipecacuanha" by Dr. B. H. Paul and A. J. Cownley. They are printed at pp. 686-692, and gave rise to the following discussion.

Mr. Holmes said it appeared from the first paper that the Carthagenas and Brazilian ipecacuanhas were practically the same, and that conclusion seemed to be supported by the chemical investigation. Another point seemed to be that the two plants were different varieties, not distinct species. There was on the table a specimen of the flower of one variety. Mr. Cownley's results were very interesting from the therapeutic point of view. It was well known that the drug from which the emetine had been removed was efficacious in dysentery, and as it now appeared that both emetine and cephaeline had an emetic action, the anti-dysenteric power was probably due to the third alkaloid. It was known that collectors of this plant were subject to an affection of the skin very similar to that which would be produced by saponin. The question arose from this paper whether when ipecacuanha was dispensed with caustic potash the emetine would not be thrown out, and only cephaeline remain and cause the expectorant action.

Mr. Martindale asked the proportion of the two main alkaloids in the drug and if it was known whether the anti-dysenteric power was due to either of the alkaloids or to something else.

Mr. Elsbrook remarked that the Carthagenas plant seemed likely to become of more importance. It struck him that the annulated rootlets were of the nature of tubers, in which starch grains were stored up for the future nourishment of the plant, and he should like to know what became of them in succeeding years. The action of light on one of these alkaloids would furnish ground for an interesting spectroscopic research, in which might be found a test for the alkaloid. He did not gather that the drug on which Dr. Paul and Mr. Cownley had been working was identical with what Professor Greenish had described, and that led him to suggest that in any such researches, if possible, a sufficient quantity of the actual drug operated on should be preserved in some central museum for the use of future investigators.

Mr. J. C. Unney said, as far as he understood, the powdered root and liquid extract used for dysentery were those from which the alkaloids had been removed, and it was quite possible that the action was due to the acid. He was glad to learn that at any rate one crystalline salt had been obtained from cephaeline, and that the process was so successful that Messrs. Merck had been able to work it on a commercial scale. It now remained to have a therapeutic investigation made in order to ascertain whether preparations should be standardised in relation to emetine, to cephaeline, or to the total alkaloid, as it had been done up to the present; but as it had been shown that Kunz's formula was incorrect, and was made for a dibasic instead of a monobasic alkaloid, the quantity of Meyer's reagent used would probably be wrong. He had on several occasions examined the acetic extract of ipecacuanha root, and found that the whole of the alkaloids were extracted, but that in heating the extract to reduce it to dryness, 15 to 20 per cent. of the alkaloids was lost.

Mr. Martindale said he understood that the so-called ipecacuanha sine emetine was not completely exhausted of the alkaloid.

Mr. Chas. Unney said these papers were very interesting from several points of view. The whole subject had been for a long time in a state of mystery, owing to their ignorance of the facts which had now being brought forward. From the pharmaceutical aspect these researches came just at the right time; it was clear that the present method of preparation was wrong, the extract being spoiled by the cooking process to which it was subjected, and he hoped in the new Pharmacopoeia the results of these researches would be embodied. Commercially, again, it was of great importance to know that the Carthagenas root, which was not admitted into New York at all, and which fetched on the market about 25 per cent.
less than the Rio, was equally good, and there seemed no reason why it should not be recognised. He had been surprised to see in a medical paper the wonderful results in dysentery of the root which had been exhausted of the alkaloid, and he felt little doubt that its efficacy was due to the ipecacuanbic acid.

Mr. C. E. Sage said he had worked on large quantities of both Brazilian and Carthagena root, and found that in respect of total alkaloid the latter was as good as a poor Brazilian. It was quite reasonable that it should be recognised. He saw no reason why the acetic acid preparation should be spoiled by so much heating.

Mr. Martin, having spoken in high terms of both the papers, said he hoped one of the results would be that in the next Pharmacopoeia they would have another standardised preparation. He could never understand why extracts containing alkaloids should be so tortured by heat, as you did not know how they might be split up. If acetic acid were properly used it might play a much more active part in the extraction of vegetable alkaloids.

Mr. E. J. Parky said it appeared from the last number of the Chemical Society's Journal that in Dr. Kunz's opinion the formula for emetine given by Messrs. Paul and Cowley was an impossible one, as it broke the law of so-called even atomicity.

Professor Attwood said it was very satisfactory to see that the Pharmaceutical Society was endeavours to focus the results of individual workers, and to bring to the medical world all that could be discovered with regard to the chemistry, pharmacy, and physics of drugs, but there was still required a great deal more light on the pharmacological side. He often wished that there were in this country a society for doing such work, so that when the Pharmaceutical Society had done its work on drugs, their medicinal action could be ascertained. It must be remembered that only those drugs whose remedial action was known could be included in the Pharmacopoeia. The compilers of the Pharmacopoeia would, of course, do all they could, but individual pharmacists would do well to experiment in the way of making galenical preparations and then publish their results, which would be of great assistance.

Mr. Cowley, in reply, said there was more cephaline in Carthagena root than in Brazilian, and more in the Brazilian stem than in the root. They had been in hopes of having some results as to the practical action of these alkaloids, but they had not come to hand in time. He could not say for certain whether the anti-dysenteric action was due to the alkaloids or not, but the de-emetinesed root generally met with did contain some alkaloid. The total amount of alkaloid in Carthagena root was generally about 2 per cent., of which about 30 per cent. was cephaline, nearly 70 per cent. emetine, and a very small quantity of the third alkaloid. It might be found that cephaline acted better than emetine, and, if so, the amount present would be of the highest importance in fixing a standard. Dr. Kunz was probably annoyed that they had found that his emetine was composed of at least three alkaloids, and he was thus led to raise a side issue about the formula. If any one objected to C6H5NO4 on the ground that the perisaid elements did not make an even number, they had only to double the numbers and the objection was gone. Various formulae had been given by different investigators, and they had simply adopted Glénard's. Kunz had never been able to get a crystalline hydrochloride.

Mr. Hills asked if there were any reason why, when the original work was done here, the alkaloids should not be manufactured in England.

Mr. Martin said he had been over Messrs. Merck's factory, and saw there something like 2,000 gallons of rectified spirit being used on which no duty was paid. Englishmen could manufacture alkaloids as well as Germans if it were not for the spirit duty.

Votes of thanks having been accorded to the authors of the papers,

Mr. Stillingfleet Johnson then gave a demonstration of the method of ascertaining the quantity of sugar in urine, devised by his father, Sir George Johnson, as recently described in the Journal (ante, p. 604). The "picro-saccharometer" used on the occasion was furnished by the makers, Messrs. C. E. Müller and Co., High Holborn, W.C.

The President proposed a vote of thanks to Mr. Johnson, which was carried unanimously, and the meeting then adjourned.

Proceedings of Societies in London.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting was held on Thursday, January 31, Mr. Sidney Davis in the chair. A paper entitled "Some Dartmoor Flowers" was read by Mr. D. P. Fuge.

The author prefaced his paper by a few remarks upon the physical aspect of Dartmoor.

He reminded his audience that the "Moor" comprised nearly the whole of central and south-west Devonshire, a county producing a very large and varied flora, and whose bluffs rock, cliffs, and sands running right away into fertile pasture ground afford habitat for most of the plants found elsewhere in Britain.

The Moor proper is bounded by downs of gorse and heather, and is itself a vast stretch of granite covered by a thin stratum of black soil, the continuity of which is broken by rugged boulders and "tors" or granite hills.

The abundance of thyme and heather was noted, and the property they had of imparting flavour to the mutton fed thereon.

The devil's bit and eyebright grow freely, and local legends connected with them were related in detail whilst those connected with St. John's wort and the royal fern were referred to incidentally. The stunted growth of the rowan and other trees was described and accounted for.

In the discussion which followed the Chairman, Miss Buchan, Messrs. Walker, Bastow, Jealors, Woodruff, and the Secretary took part.
ROYAL INSTITUTION OF GREAT BRITAIN.

THE INTERNAL FRAMEWORK OF PLANTS AND ANIMALS.

In continuation of his lectures on the internal framework of plants and animals, Professor Stewart dealt on Tuesday, February 5, chiefly with the means by which sponges are provided with the necessary support. Drawing attention to the calcareous spicules found in many sponges, he pointed out that although these are formed by the protoplasm, when examined with the polariscope they behave exactly as if they had been carved from a solid piece of calcite. In hexactinellid sponges the spicules, he observed, were six rayed as in the glass rose sponge. In this species, which lives at great depths in the sea, the spicules are not fused or cemented together, but simply entangled. By means of spiral bundles of spicules driven into the globigerine ooe, the creature anchors itself to the bottom; these spicules may attain a length of two or three feet. A common sponge, *Elastochorda penicula*, was selected to exemplify the structure. Here branched canals excavated beneath the ectoderm communicate by ciliated chambers at the terminations of their ramifications with the branches of similar cavities proceeding from the endoderm. By the flagella in the chambers circulation of water is maintained. In the siliceous and horny sponges these flagellate cells are much smaller than they are in the calcareous. Tetractinellid sponges have four-rayed spicules; in the *thetid* group of these the spicules are held together by the interlocking of the ramifying terminations of the rays or by claspers with which one ray encroles its neighbour. In *Discoderma* the spicules develop into protective plates. Bundles of spindle-shaped spicules form the supporting structure of monaxonon sponges; they are frequently held together by a horny material—sponglin.

The higher of the horny sponges, *e.g.*, *Busoporia*, are free from spicules and form the sponge of commerce. Horny fibres are produced by the co-operative action of a number of mesoderm cells which deposit the material of the fibre, and thus both the thickness and length increase. In the curious sponge, *Dorivina*, spicules of horny material are found. Horny sponges growing on rocky shores may consist of sponglin alone, but the same sponge on a sandy shore may accumulate sandy particles on its adhesive surface to such an extent as to conceal the sponglin almost entirely.

Finally, Professor Stewart drew the attention of his audience to cases of symbiosis between sponges and hydroids, in which, as in symbiosis in the plant world, mutual advantage results from such cooperation. Symbiosis, he said, might also occur between sponges and seaweeds.

The objects exhibited under the microscope were chiefly sponge-spicules, as for instance the hooked spicules of *Hymedesmia*, plate spicules of *Discoderma*, articulating skeleton spicules, tetractinellid spicules, etc. Specimens were also shown of *Ephydatia fluviatilis*, *Dendrilla rosea*, *Marchesetta spongiformes*, *Dysoidea*, etc.

THE ANTITOXIN TREATMENT OF DIPHTHERIA.

A goodly audience assembled on the 8th inst. to hear Dr. Sims Woodhead discourse upon the "Antitoxin Serum Treatment of Diphtheria." At the outset the microscopic characters of the diphtheria bacillus were figured and described. The organism seems often to assume a more or less oblong shape, more developed at the extremities than at the periphery, but modifications often occur by which it becomes wedge-shaped, pointed, or curved. The diphtheria bacillus, which is characteristic of the disease, is always found upon the leathery or false membrane of the throat. Dr. Woodhead stated that, although he had investigated about 600 cases during the last five weeks, yet in nearly every instance these typical bacilli had been present, and always in the same position, that is to say, confined to that part of the throat where the local lesion, which follows the soreness, had taken place.

Reference having been made to the investigations of Klein in the bacteriological, and Martin in the chemical, departments of the subject, the formation of the diphtheria toxin was described. The inflammation of the mucous membrane of the tonsils and the upper part of the gullet and windpipe is, in fact, caused by the presence of the bacillus, already alluded to. As a result, an intensevulnent compound called the diphtheria toxin is formed, which afterwards becomes changed, being broken down into two less poisonous compounds, the first of which is still confined to the throat, the other being found in the spleen. On injecting a certain amount of this diphtheria toxin into the subject selected for experiment, certain disarrangements of the system will be observed, including rise of temperature, change of pulse, general fever, and also in many cases a peculiar form of paralysis which is due to the action of the less poisonous variety of the toxin, formed at a later stage.

Several photographs were shown on the screen to illustrate the appearance of nerves of animals poisoned with the toxin produced by the bacillus in the spleen. Now when the toxin is injected into an animal the effects, of course, vary with the dose. Normally they include the characteristic sore throat and inflammation of the surface of the mucous membrane. Obviously some method had to be devised of regulating the dose. This was effected by modifying or diluting the toxin so that the first dose did not produce a fatal result, but only caused a disturbance of the system. It was found that by using an old culture of the toxin, or one that had been treated with iodine and potassium iodide, a modified poison was produced which answered the purpose. Then the dose was gradually increased, the animal experimented upon gradually becoming immune to enormous doses just as a victim to the morphine habit does. This condition is supposed to be due to the power which certain cells of the organism have of accommodating themselves to the action of the toxin, in virtue of which the patient is protected from further action on the part of the poison. The cells form or secrete a substance which is antagonistic to the action of the toxin or assume a condition which enables them to secrete it. The antitoxin serum is specially formed in the connective tissues or white blood cells.
Dr. Woodhead stated that he was very reluctant to accept the antitoxin treatment when it was first promulgated, having a very lively recollection of the disastrous results which attended a system of treatment which had been previously advocated for the disease. He was therefore enabled to approach the subject without any enthusiastic bias in favour of it. Various subjects were selected for trial of the treatment, and after rabbits and sheep had been discarded it was found that horses were by far the most suitable, as they were comparatively unaffected by moderate doses of the toxin, only local action ensuing. Independently of that, the serum obtained from horses does not change—it mixes well with diluents, it does not form albumin when excess is used. After the first local action has subsided the horses have splendid health; in fact, Dr. Woodhead caused some amusement by stating the difficulty they had had with them during the severe weather, as since they could not be exercised sufficiently they had become almost unmanageable.

The toxin is made by the following process:—The diphtheria bacillus, prepared artificially, is grown in a "broth" composed of 4 per cent. sodium chloride and 2 per cent. peptone. This "broth," which must be faintly alkaline (as the bacillus will not grow in acid media), is contained in a flat-bottomed flask which has been sterilised. The mouth, which is about half-inch in diameter, is plugged with sterilised cotton-wool and fitted with a cork provided with tubes, also plugged at the ends with sterilised wool, to allow of the passage of a continuous current of sterilised moist air through the flask. The flask is then placed in a chamber kept at the temperature of the body. If air were not passed through only a small amount of toxin would be formed, but by its agency the fluid becomes cloudy at the end of twenty-four hours, indicating the formation of the poison. The toxin, though very virulent at first, gradually loses much of its activity. The lecturer then described briefly the method of administering the toxin to horses.

With regard to fixing some strength of the antitoxin serum, the English standards are made by comparison with the poisonous dose of the toxin itself on a standard guinea-pig. Thus an antitoxin serum of "100 strength" is such that 1/5 C.c. of it would theoretically counteract 10 times the poisonous dose of diphtheria toxin administered to a guinea-pig of fixed weight.

After alluding to the good results which had attended Klein’s investigation on the action of the serum as a prophylactic, Dr. Woodhead dealt with the statistics bearing on diphtheria. These showed an alarming increase in the number of cases and deaths during the last few years, the majority of cases of fatal results being amongst children.

Dr. Woodhead is sanguine of the success of the treatment, both as a preventive and curative agent. He alluded to the good results met with in its use in the wards. The patients, and especially the children were cheerful and presented a marked contrast to the old method of treatment. In conclusion, he deprecated the statement that the rash sometimes met with during the course of treatment was caused by the serum; it was rather a natural outcome of the disease itself.

CHEMICAL SOCIETY.

A meeting was held on Thursday, February 7, the President, Professor Armstrong, F.R.S., in the chair. The following papers were read:—

THE ACTION OF HEAT ON ETHYLIC
β-AMIDOCRUCONATE.

BY DR. N. COLLIE.

Ethyllic β-amidocrotonate is the salt formed by the action of ammonia on ethyl acetoacetate and has the formula C₂H₅C₂H₄CHOOC₂H₅ and it has been shown that it yields on condensation pyridine derivatives. When ethyl β-amidocrotonate is purified by distillation in vacuo, there is always a small amount of a crystalline residue left in the distilling flask, which was shown to be ethyl dimethylpyridinemonocarbonyl of the formula—

\[ \text{CH}_₃\text{C} - \text{NH} - \text{COH} \]

\[ \text{COOCH} - \text{CO} - \text{CH} \]

When the operation of heating is performed at the ordinary pressure, i.e., in an open dish, about 50 per cent. is converted into a resin, which on distillation yielded a product from which three substances were separated, examined and identified.

The largest portion was found to be a pyridine compound, the ethoxy-derivative of 2,4-dimethylpyridine—

\[ \text{CH}_₂\text{C} - \text{N} = \text{C} \text{OEt} \]

\[ \text{C} - \text{C} \text{(CH}_₃)_₂\text{CH} \]

since on reduction with hydrogogen iodide it yielded ethyldihydropyridine and hydroxylutidine. The original substance was obtained from hydroxylutidine by chlorination with phosphorus pentachloride and subsequent treatment with sodium ethoxide. The following equations represent the reactions:

(i) \[ \text{C}_₂\text{H}_₅\text{N(CH}_₃)_₂\text{OH} + \text{HCl} = \text{C}_₂\text{H}_₅\text{N(CH}_₃)_₂\text{OH} + \text{CH}_₃\text{I} \]

(ii) \[ 2\text{CH}_₂\text{H}_₅\text{N(CH}_₃)_₂\text{OH} + \text{PCl}_₃ = 2\text{CH}_₂\text{H}_₅\text{N(CH}_₃)_₂\text{Cl} + \text{POCl}_₃ + \text{H}_₂\text{O} \]

(iii) \[ \text{C}_₂\text{H}_₅\text{N(CH}_₃)_₂\text{Cl} + \text{NaOH} = \text{C}_₂\text{H}_₅\text{N}\]

\[ \text{(CH}_₃)_₂\text{OC}_{₂}\text{H}_₄\text{NaCl} \]

The ethylolutidine is formed by condensation of two molecules of ethyl β-amidocrotonate and elimination of water, ethylene, carbonic anhydride and ammonia.

\[ 2\text{CH}_₂\text{C(NH}_₃)_₂\text{CH} - \text{COOC}_₂\text{H}_₅ = \text{CH}_₂\text{N(CH}_₃)_₂\text{OC}_₂\text{H}_₅ + \text{H}_₂\text{O} + \text{NH}_₃ + \text{CH}_₃\text{OH} + \text{CO}_₂\]

The second substance examined was obtained from the resin by treatment with aqueous hydrogen chloride, when the substance is left as an insoluble oil. It proved on examination to be a derivative of dimethylpyrrol, \( \text{C}_₄\text{H}_₈\text{(NH)(CH}_₃)_₂\text{NH} \).

The remaining substance, which was only found in small quantity, was obtained crystalline from acetone, and is probably a true amidohydroxy-pyrilid. It has the formula \( \text{C}_₄\text{H}_₆\text{N}_₂\text{O} \), and yields methylpyridine with zinc dust, and is a monacidic base. An endeavour was made to prove the presence of the

* Vide J. C. S., 1891; Trans., p. 172, Part I.
amidogen group by disossiating, but decomposition occurred.

Four substances have thus been identified amongst the products of condensation by heat of ethylc \( \beta \)-amidoacronate, namely (1) ethyl dimethylpyr- 

demonoacbarboxylate \( C_4H_7NO_3 \); (2) ethoxylutidine, \( C_8H_7(CH_2)_2(OEt)N \); (3) dimethylypyrrol, \( CH_3NH(CH_2)_2 \); 

(4) probably amidoxydroxy - plocolina, \( CH_2N(NH_2) 

\( (CH_2)(OH)(2,4,6) \).

THE ACIDIMETRY OF HYDROFLUORIC ACID.
BY PROFESSOR HAGA.

Experiments were made to determine the most suitable indicator to use in the titration of hydrofluoric acid. It was found that phenol - phthalein answered admirably with potash or soda, the colour being distinctly seen in the platinum dish. Roscoio acid answers as well as phenol - phthalein, and has the additional advantage of being able to be used with amonnia.

Cochineal and brazil wood answer fairly well, but methy1-orange is useless.

With litmus the colour change is somewhat complicated, though accurate results can be obtained by an experienced worker; the author, however, does not recommend the use of litmus. From experiments on the behaviour of the acid with litmus and alkali, it is probable that the molecule of hydrofluoric acid is polymeric and may be \( HF_2 \) or \( HF_4 \).

REMARKABLE MOLECULAR CHANGE IN A SILVER AMALGAM.
BY MISS LITTLETON.

When silver amalgam is heated, swelling occurs, there is a notable increase of volume, and gas appears to be given off. It was found that the greatest increase of volume occurred when the amalgam was made of silver and mercury in the proportion required for \( AgHg \). By heating in a vacuum it was found that no appreciable amount of gas was given off, and thus the change in volume and other appearances noted must be due to molecular change. A similar effect is noticed on heating potassium or sodium amalgams, and hence silver behaves in a similar manner in this respect to other metals in the same series in the periodic table.

THE COMPOSITION OF ANCIENT SILVER ORNAMENTS FROM PERU.
BY MISS WALKER.

Certain silver ornaments from graves in Peru were examined and the metal analysed. The metal consisted of about 85 per cent. silver, 13 per cent. copper, and 1.15 per cent. of gold. Hence it is inferred that the silver used was a native silver, and that the practice of working up silver from the ore was posterior to the date of the ornament.

Another ornament examined appeared to be an alloy of iron, lead, and zinc, with silver, copper, and gold.

A paper on "The Electromotive Forces of an Iodine Cell," by A. P. Laurie, M.A., was taken as read.

LINNEAN SOCIETY.

At the meeting on Thursday, February 7, Mr. W. Botting Hemaeley, on behalf of the Director of Kew Gardens, exhibited dried specimens and floral dissectons of a number of interesting new plants from Japan, Western China, and Formosa, collected respectively by Mr. F. E. Smiles, of the Royal Survey Department, Mr. W. Hancock, F.L.S., and Dr. A. Henry, F.L.S. We purposely omit the names because Mr. Hemaeley has not yet published them. The most curious among these plants was described as a new genus of Scitamineae, a small plant having grass-like leaves and minute unisexual flowers enclosed in coloured bracts, and destitute of labelnum and all other stamindalia. It is a native of the mountains of Northern Japan, where doubtless many peculiar plants yet remain undiscovered.

A large-leaved Lysimachia from the same region has the habit of Sarraea in Scitamineae. The showiest plant among them was a Jasminum from Western China, with yellow flowers of large size and great substance, an ornamental plant almost worth a journey to China to procure. From Formosa there were some Cyrtandrae, including a new genus, and new species of Ventilago, Actinidia, Zanthoxylon, Msonas, Heliocar, etc.

Mr. Thos. Hanbury exhibited a large number of fruits from his garden at Ventimiglia, including several varieties of oranges, citrons, and pommeleos, etc., and several curious fruits resembling annals (Medicago scutellata and plagiopera), and cattlerpillars (Scorpius subviolaceus). Mr. Thos. Christy exhibited a curious Chilian drug named llerata, in which the stems formed a solid, compact mass; also fruits, bark, and exudation of the Afrian Kino tree (Pterocarpus ornatus).

Provincial Transactions.

SHEFFIELD MICROSCOPICAL SOCIETY.

At a meeting of the above Society held on Friday, February 1, the President, Dr. Arthur Hall, occupied the chair, and the following paper was read:—

GRINDING AND PREPARING SECTIONS FROM HARD TISSUES.
BY W. B. TOLSFUTT, L.D.S.

The lecturer dwelt on the various methods of cutting through the hard enamel of teeth, such as sawing and filing. He had been very much disappointed with the results given by those methods, and recommended the following process (although a wasteful one) until a ready means could be found of cutting through the enamel. A tooth is taken and held against the side of a revolving fine corundrum wheel till one side is ground flat, then that side is brought to the most perfect polish it is capable of receiving, on a piece of buff leather with some putty powder on it. Afterwards take a piece of stout glass and put a little old and, consequently, tough Canada, balsam on it, warm and spread it a little larger than your section. Let the balsam cool down until it is "tacky," then press the polished side of the tooth
into close contact with the glass, and clip it. When quite cold the grinding may proceed as in the first part of the operation till you get the required thinness, when that side may also be polished. The hard balsam round the section supporting and protecting the edges, they will not be fractured and made jagged and untidy. By not putting the tooth on to the glass plate until the balsam is somewhat cooled, the polished surface remains free from cracks, and the balsam does not run into the tubular structure of the dentine. Another method recommended by the lecturer was as follows: — A slice of dental or other hard tissue of moderate thickness is placed between a plate of ground glass and a flat stone (such as an Arkansas or Lake Washita stone), with water and a pinch of levigated pumice powder, and by a rotary motion of the upper glass, gradually rub the section down till it is thin enough for examination with even the highest powers of the microscope. But towards the end of the process the section should be carefully watched, for as the glass and stone, or the two glasses, get closer together, and the section thinner, one turn more of the upper glass will sometimes result in the total disappearance of an hour’s work. Having ground the section sufficiently thin by either of the before-mentioned plans, it remains to be mounted in a suitable medium for examination.

The lecturer then went on to describe the decalcification process. Chromic acid, he said, was most frequently used for this purpose, as it hardens the soft and softens the hard parts of the tooth, both changes taking place simultaneously. It was also useful for fully-developed human teeth, also for developing jaws of mammals in which a fair amount of dentine, enamel, and bone have been already formed. But for a handy and good all-round method there was nothing to equal a saturated solution of common alum acidified with hydrochloric acid, half a dram to each ounce. Steeping the tooth or teeth in this for about three weeks leaves the tooth with the consistency of cork. If it is now soaked in glycerin for a few days, it may be imbedded and cut into thin sections by any of the usual microscopes. As to the staining of hard tissues Mr. Tolputt mentioned logwood and borax-carmine as coming first in the list. In staining with chloride of gold it really did not matter whether the section be fresh or not. The method described by Dr. Bödecker had given the best results. He immersed the section, whether cut from a decalcified tooth or ground down from a hard one, in a solution of carbonate of soda for an hour. Then he placed it in a solution of chloride of gold (which must be neutral) and left in the dark for another hour; it was then placed in the carbonate of soda solution for a few minutes and transferred to a 1 per cent. solution of formic acid and kept warm over a bath for about an hour and a half. Finally the section was mounted in glycerin jelly, not in Canada balsam. Hard tissue sections after having been stained should be well washed and dehydrated, then cleared in either oil of cloves, cedar or bergamot, and finally mounted in the usual way.

On the motion of Mr. George Ellinor, seconded by Mr. B. W. Winder, a hearty vote of thanks was accorded the lecturer for his valuable paper.

THE CAMBRIDGE PHARMACEUTICAL ASSOCIATION.

On Friday evening, February 1, a lecture was given to the above Association in the chemical laboratory of the Technical Institute by Mr. Fred Stockley, Teacher of Chemistry at the Technical Institute, on

(a) Diffusion of gases and application of gaseous diffusion.

(b) Liquid diffusion — dialysis — crystalloids and colloids.

(c) The detection of poisons in complex organic compounds by means of dialysis.

The lecture was illustrated by numerous successful experiments, by means of which the various processes were fully explained and the results proved.

Mr. Alderman Deck, F.C.S., occupied the chair, and at the conclusion of the lecture voted a very hearty vote of thanks to Mr. Stockley, which was seconded by Mr. D. Greenwood, and carried with acclamation.

Scottish Transactions.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

At the meeting held on the 7th inst., Mr. John Foster, Vice-President, in the chair, the Association was honoured by Mr. George Lunan, of Edinburgh, with a valuable contribution in a practical and well-considered paper entitled “Notes on Revision of the Pharmacopoeia.” Members were rejoiced to see their President, Mr. W. L. Currie, again in their midst, though he preferred to let the duty of presiding over them rest in other hands. The Chairman having introduced Mr. Lunan, who was warmly greeted by the members, the paper was then read.

Messrs. John McMillan, Dunlop, Robb, the President (W. L. Currie), and the Chairman expressed their sense of the honour Mr. Lunan had done the Association, and made some general observations on the subject, and a hearty vote of thanks was afterwards accorded.

Correspondence.

OUR WEIGHTS AND MEASURES.

SIR,—Very much uncertainty seems to exist in the minds of most of us with regard to our weights and measures, more particularly in the relation of one to the other, and I think it is due to our semi-scientific training and especially to our Pharmacopoeia. It may be right, from a scientific point of view, that some sort of relation should exist between the grain and a fluid measure, such as the grain measure; but, from a practical point of view, so far as the medical man who orders, and the dispenser who executes the order are concerned, it seems to me quite wrong that a one per cent. solution should be one per cent. by a measure that the medical man never thinks of, and the dispenser never uses, namely, the grain measure. What use is it to the doctor to know
that liq. arsenumica or liq. strychninæ hyd. contains 1 grain in 100 grain measures, when such a measure is not used in compounding prescriptions? The Pharmacopoeia recognises the right thing in ordering inj. morph. hypoderm., for, of it, the strength is not 1 grain in 10 grain measures but 1 grain in 10 minims. The Committee seems indisposed to adopt the metric system by which all these vagueness would be overcome, but in view of a new edition of the Pharmacopoeia and the same system being preserved for another decade, would it not be advisable to drop the grain measure from the formulas by which our compounds and solutions are made, and reckon 480 minims to the ounce? No scientific accuracy would be lost, but a gain would be effected, as now we find quantities prescribed, varying from 87 to 90 grains per pint, to make solutions called one per cent solutions, and 9 grains to 16 fluid drachmas in liq. strychn. hyd. against 9 grains to 164 fluid drachmas in liq. atropinae sulph.

From this reasoning I would draw the two following deductions:—

1st. The grain measure should be expunged from the body of the Pharmacopoeia, because it is not practical and is misleading.

2nd. That it is unnecessary in the Appendix, because the metric system is all that can be desired.

With regard to the second deduction there is the argument that some men have their apparatus graduated in decimals, etc., and that they have a vested interest in the old system. These men are few, and they are familiar with the relation that exists between the two systems, so it is unnecessary to encumber the Pharmacopoeia with special instructions for them. The vagueness and uncertainty is not confined to the medical man in the practice of his profession and the pharmacist in his calling, but it frequently crops up in our more scientific literature. Within this year I have seen in the Pharmacopoeia the factor 48 given by a very eminent investigator for the conversion of percentage into grains per ounce. No doubt it was a slip, but it is one that frequently arises, and in use produces a grave error, about 10 per cent. Again, within the last few weeks a writer in the Lancet, and a man whose name is known throughout the country, boldly asserted that one Cc. is equal to 15 492 minims, and refused to be convinced of his error. To remove the grain measure from the Pharmacopoeia would not overcome these difficulties, but its tables of weights and measures should be more explicit on these points, and I would humbly suggest that such lines as the following should be inserted in their proper places:

1. A percentage solution in the body of the book means grains per 100 minims.

2. A percentage solution in the Appendix means grammes per 100 Cc.

3. The factor for converting metric percentages into grains per ounce is 4.875.

4. 1 Cc. = 15 493 minims.

A useful note for the chemist to remember in dispensing foreign prescriptions and sufficiently accurate for most purposes is: 4 grammes = 23 gr., and 33 Cc. = 15 gr.

Phenol.

Sir,—I do not know that a reply to Mr. Dott’s letter (ante, p. 600) is necessary. It may be permitted to me, however, to point out that my remarks were not on the method of determining the boiling point of a liquid speaking generally, but of carbolic acid in particular. The suggestion of placing the bulb of the thermometer in the liquid was made because it had been found practically useful, and if adopted in the Pharmacopoeia might lead to uniformity in this determination, a great desideratum when one considers the various (and as Mr. Dott says, faulty) methods which it is possible to use. Commercial carbolic acid is a very good article, but it is not chemically pure.

What is wanted is the temperature at which the mixture is in a state of ebullition, and that I think may be obtained by the method indicated. Of course when dealing with a pure substance the thermometer must be placed in the vapour. The object of the note was to show the necessity for increased stringency in the tests for carbolic acid, and not to advocate any special method of determining the boiling point, so long as a definite method is given. I would like to repeat what I said in my paper, that for various reasons the melting point is of much greater value than the boiling point as a test for the degree of purity of commercial carbolic acid.

Edinburgh.

GEORGE COUL.

Edward Bristow, C.M.G., F.R.C.S., Administrator-General of British Guiana, the following remarks are made bearing upon an article published in the Pharm. J., December 8, on ‘Pharmacy in Demerara.’ These remarks seem intended as a correction, and I have therefore ventured to hand them to you for publication.

‘In the Journal article of December 1 on ‘Pharmacy in Demerara’ the writer has made some mistakes. Opium and ganjah are largely imported and largely consumed by the East Indian immigrants (106,000), and there is a duty of 16s. 8d. per lb. levied. The importer has to pay £200 as annual licence, and the retail dealer pays £4 13s. 4d. licence per annum. I cannot give you the amount yearly imported, but the quantity is large, and it used to be, and no doubt is, smuggled. It is necessary in order to protect these dealers that chemists and druggists should not be allowed to compete with licensed dealers. The retailers have to keep books showing sales, and are closely watched by the Commissaries of Taxation. I agree with him to the laxity about qualification of chemists and not very long ago I was served in a shop by the porter who took down the bottle I pointed out and sold me an ounce of what I wanted.’

17, Bloomsbury Square, W.C.

E. M. HOLMES.

Dr. Brunton on Pharmacopoeia Revision.

Sir,—The article by Dr. Brunton on the approaching revision of the British Pharmacopoeia will doubtless attract considerable attention, and ought to receive the most earnest and careful consideration of every pharmacist. I have carefully read—and re-read—the article, and can only conclude either that pharmacists generally have a very mistaken and erroneous idea of their position in medicine, and their relation to the medical profession and to the Pharmacopoeia, or else that Dr. Brunton is himself very wide of the mark. And I think the latter is the case. I cannot, in the first place, understand his conclusion that because the object of the Pharmacopoeia is stated to be ‘to afford to the members of the medical profession and those engaged in the preparation of medicines throughout the British Empire, one uniform standard and guide whereby the nature and composition of substances to be used in medicine may be ascertained and determined,’ therefore it is intended ‘primarily’ for the members of the medical profession, and ‘secondarily’
only for chemists and pharmacists. I suppose that where two classes of persons are specified, one class must come first, but precedence in order does not necessarily imply any superior or primary, let alone exclusive, claim to consideration. Moreover, the very fact that the main object of the Pharmacopoeia is stated to be to ascertain and determine "the nature and composition of the substances to be used in medicine" indicates pretty clearly that the Pharmacopoeia must of necessity touch the pharmacist in his life-work far more closely than it does the medical man.

Dr. Brunton unconsciously emphasises this very point when he states that "in the consulting rooms and libraries of doctors in general the British Pharmacopoeia is generally conspicuous by its absence," whilst the same fact serves to explain where the "thousands of copies issued by the Medical Council," concerning the destination of which Dr. Brunton expresses such bewilderment, have really gone. Perhaps Dr. Brunton would be able to give us an estimate of the number of medical men in this country who are in the habit of endeavouring to ascertain the nature and composition of the substances they use in medicine, and he might, at the same time, offer his opinion on the question as to whether this is not the work for which the pharmacist is specially qualified, which is, in fact, the great reason and justification for his existence. It is well to have placed on record the fact that the Pharmacopoeia is of little or no use to medical men; and it may be of service to place alongside it the further fact that it is the one book which is essential in every pharmacy, and the one which the pharmacist is in daily, almost hourly, need of consulting.

All pharmacists will agree with Dr. Brunton's opinion that the British Pharmacopoeia is still far from being perfect. But if it is imperfect from the standpoint of the medical man, it is quite as much, if not more so, from that of the pharmacist and public analyst, both of whom have a claim to consideration in the matter of revision, second only to that of the members of the medical profession.

But whilst agreeing with Dr. Brunton that the Pharmacopoeia is in considerable need of improvement, I am just as certain that any attempt made to improve it will be more serviceable, if the lines laid down in his article would not only entirely alter its character, but would also tend to seriously impair its efficiency for the purposes for which it is published. The proposals of Dr. Brunton are distinctly retrograde in their character, and to accept his suggestions would simply be to make the national (or Imperial) Pharmacopoeia a sort of repository for hitherto stored up drugs, precariously stored as to to answer the demand and incompatibility, instructions as to how to prepare them. The suggestions contained in the article are for the introduction of new and improved medicines. The opinion of physicians generally will be that the Pharmacopoeia should not be degraded into an instrument for supplying what is lacking in the education of medical men. Surely such elementary knowledge as that sketched in Dr. Brunton's article might be acquired during a five years' course of study at a medical school. Without the necessity of over-burdening the already overcrowded pages of the Pharmacopoeia, it would be a boon both to medicinal men and the pharmacist.

The system of standardisation should be extended and developed. In connection with this subject a vast amount of work has been done on the pharmaceutical side, and there is ready to hand an accumulated mass of research which only need checking on the physiological side before being available for use by the Pharmacopoeia Committee. Many official remedies are out of date and might be dropped. Some of the B.P. processes, in addition to those for the production of the two obsolete preparations mentioned in Dr. Brunton's article, require modification and revision, and the use of the metric system of weights and measures ought to be legalised.

As for the purely pharmaceutical portion of the work involved in the production of the forthcoming Pharmacopoeia there is no doubt that in the hands of the committee nominated by the Pharmaceutical Council it will be thoroughly and efficiently done. The annual reports sent in to the Medical Council by the official reporter bear eloquent testimony to the fact that the pharmacists of this country are playing a not unworthy or unimportant part in developing and perfecting the art and practice of pharmacy. And it is not too much to affirm that in carrying out any proposals which may be made for the improvement of the Pharmacopoeia on the pharmaceutical side, British pharmacists will be found quite equal to the occasion.

R. Weight.

Tabloids and the New British Pharmacopoeia.

Sir,—May I ask your corresponding "Galen," in your issue of February 9, to differentiate between pills and tabloids, or tablets? The bulk of the B.P. pills are now supplied by wholesale galephric preparation manufacturers and are simply dispensed according to label. If dispensing chemists are to be considered as the pharmacists' cooks, why are the mass of the galephric preparations purchased in bulk and dispensed in good faith as of the "substance and quality demanded" without further proof? It appears to me your correspondent is merely "staining at the gown."

"Galephric."

Correction.—In Mr. Kemp's letter, published last week on page 684, for "Pharmaceutical Councillor" read "Pharmaceutical Chemist."

Notices to Contributors.

Communications should reach the Editorial Department, 17, Bloomsbury Square, W.C., not later than the first post on Wednesday, if publication is desired in the next issue of this Journal; though prompt publication cannot always be guaranteed. Matter intended for publication must be written in ink, on one side of the paper only, and be authenticated by the name and address of the writer; and if not so authenticated, will not be accepted for publication. Subscriptions to the Journal may be taken by anonymous communication, and contributors are requested, as far as possible, to append their proper signatures rather than pseudonyms, a greater value being thus given to any opinions expressed.

Communications received from Messrs. Botth, Bullen, Clarke, Clay, Dyer, Ellis, Everett, French, Jasper, Kemp, Kirkley, Kirkpatrick, Meester, Moth, Naylor, Suttle, Wellesme, Wright.
THE MONTH.

Titanium and its Compounds. H. Moissan obtains blue titanium and its protioxide, titanium nitride, Ti₃N₄, metallic titanium, and crystallised titanium carbide, Ti₃C₂, by heating a mixture of titanium and carbon in the electric furnace. The metal itself is the most refractory substance yet obtained by this means, being more infusible than vanadium, and considerably more so than chromium, tungsten, molybdenum, and zirconium. Its properties, regarded as a whole, resemble those of the metalloids, and more particularly silicon (Comp. rend., cxx., 290).

Reactions of Chelidonine. M. Battandier mixes a drop of guaiacol and about 0.6 Cc. of sulphuric acid (s.g. 1.84) at the bottom of a porcelain capsule, then places small pieces of chelidonine near the edge, and in a few moments bright scarlet streaks of great intensity descend from the pieces, the reaction persisting for some time. With guaiacol carbonate the colouration is less intense. When the guaiacol is replaced by thymol, a rose coloration is obtained, which lasts for more than twenty-four hours, and only becomes slightly purple as hydration of the acid takes place. The chelidonine should be introduced before the acid gives a blue colour with the thymol. Ordinary phenol gives only a slight rose tint with chelidonine and sulphuric acid; oil of cloves gives a purple colour; naphthalene, dark green streaks; 2-naphthol, brown streaks passing to violet; pyrocatechin, a rose colour passing to violet; hydroquinone, resorcin, and phloroglucin, yellowish streaks; pyrogallol, red turning to yellow, and then disappearing; and gallo-tannic acid, yellow passing to bright green. All oxidising agents produce the same green coloration as nitric acid when added to chelidonine dissolved in sulphuric acid (Comp. rend., cxx., 270).

Dimorphism of Cinchonine. J. Jungfleisch and Léger find that this isomer of cinchonine, which has a specific molecular rotatory power, is not only dimorphous but that the two forms readily change into each other. The clomorphbic form is stable at the ordinary temperature, whilst the orthomorphbic form is the same at the boiling point of ether, about 35°. Some twenty degrees, therefore, constitute the difference between the temperatures at which crystallisation takes place in the two cases. Hydrate of cinchonine can be obtained in prismatic crystals containing two molecules of water by heating the anhydrous base (n.p. 139°) with water. Cinchonine, a close isomer of cinchonine, also forms a hydrate, which occurs in fine needles containing three molecules of water (Comp. rend., cxx., 328).

Lactate of Methylene. L. Henry describes an ethereal salt of a new kind, methylene lactate, obtained by the action of lactic acid upon formic aldehyde. It is a colourless liquid with a strong odour recalling that of acetaldehyde; its density at 2° is 1.07, and it boils at 153°-154° under a pressure of 764 Mm. Its pourous density was found to be 3.47, and its spicrhal formula is CH₃O₂. The ether is readily asealed into a crystalline mass which melts at -28°. It is insoluble in water, but when warmed with that liquid decomposes into lactic and formic aldehyde (Comp. rend., cxx., 333).

Boron Steel. Moissan and Charpy have recorded some experiments made with an alloy of steel and boron, chiefly with a view to comparing the effect of the latter on the hardness, temper, etc., of the alloy as compared with steel containing carbon only. The boron steel was prepared by heating pure amorphous boron with reduced iron, in the proportion of 1 to 9. This boride of iron was then added to very soft steel previously melted, and the mixture twice fused. The alloy was found to contain 53 per cent. boron, 17 carbon, and 3 manganese, with traces of silicon, phosphorus, and sulphur. In physical properties it closely resembled soft steel. In tenacity, however, it equaied hard steel upon which no impression could be made by a file, the boron steel being malleable and easily cut with a file. A table is given showing the breaking strain for wires of equal dimensions of boron steel, soft steel, and hard steel respectively (Comp. rend., cxx., 139).

Boride of Iron. H. Moissan by fusing together boron and iron in an electric furnace. To remove uncombined iron, the fused mass, after cooling, is treated with diluted hydrochloric acid, in which the boride of iron is insoluble. It is described as occurring in brilliant crystals of a yellowish-grey colour, having a density of 7.15 at 18° C. The composition of the crystals was determined by acting upon them with nitric acid, which dissolved the iron as nitrate and converted the boron into boric acid. The latter was extracted by methyl alcohol, treated with a known weight of quicklime, and weighed as borate of calcium, the iron being precipitated and weighed as oxide. The properties of the new compound are described, and reference is made to other borides, as well as analogous compounds of silicon and carbon. The author suggests that these bodies may provide useful data for determining the valency, etc., of the elements concerned (Comp. rend., cxx., 178).

Kjeldahl's Process. M. Delépine finds that the determination of nitrogen in chloroplatinate of trimethyamine by Kjeldahl's method yields results below those calculated from the formula of the body. The nitrogen in ammonium chloroplatinate was also determined with a similar result, less than one-third of the nitrogen known to be present appearing in the distillate as ammonia. The deficiency is attributed to chloride from a portion of the chloroplatinate acting upon the rest, with formation of free nitrogen (Comp. rend., cxx.).

Separation of Zinc, Copper, etc. H. N. Warren suggests a new method for separating zinc from copper and other allied metals, which consists in dissolving the alloy in strong sulphuric acid, adding a few coils of magnesium tape, and maintaining the solution at about 100° F., until the whole of the copper is precipitated. If tin, antimony, or other metals of the same group are suspected, the copper precipitate must be further examined. Any free sulphuric acid in the filtrate should then be neutralised by adding a strong solution of sodium acetate and raising to boiling point, when any iron present will be precipitated as tribasic acetate, whilst the zinc sulphate will be converted into acetate. Thick sheet or rod magnesium is next added to the solution, and...
Hydrogen is evolved simultaneously with the entire precipitation of the zinc \((\text{Chem. News, lxix, 92})\).

**Arabinoscholar and Xylocholar.** M. Hanriot, continuing his researches on the combinations of sugars with chloral, describes the production of the above compounds from chloral and arabinoxylose respectively, in presence of a trace of hydrochloric acid. From arabinose two isomers, \(\alpha\) and \(\beta\)-arabinoscholar, were obtained, having the empirical formula \(\text{C}_9\text{H}_{12}\text{Cl}_2\text{O}_6\). The \(\beta\)-variety is deposited first, and has a melting point of 183°C. In its general behaviour it resembles \(\beta\)-glucoscholar. Trisacetyl and dibenzoyl derivatives were prepared from it. The mother liquor from which the \(\beta\)-compound was obtained yielded the \(\alpha\)-arabinoscholar, melting at 124°C. This was found to be much more soluble in ordinary solvents than its isomer. The dibenzoyl derivative was prepared, but the acetyl compound could not be obtained in a pure condition. Only one variety of xylocholar was obtained, the author suggesting that its failure to separate as the pure isomer might be due to its solubility in the syrupy mother liquor. The xylocholar prepared melted at 132°C, and was much more soluble in water than arabinoscholar. A graphic formula is given which accords with the formation of the trisacetyl derivatives and a monobasic acid having the formula \(\text{C}_7\text{H}_6\text{Cl}_2\text{O}_6\) ((Comp. rend., cxx, 153).

**Lacose and Laccol.** G. Bertrand has previously shown \((\text{Ph. J. [3], xxv, 1087})\) that the latex of the Tonquin lacquer tree contains a ferment which causes it to oxidize rapidly when exposed to the air, and thus renders it insoluble in the usual solvents. This laccol seems to act by inducing oxidation of an alcohol-soluble oily liquid, termed laccol, which possesses energetic rubefacient properties. The laccol, in turn, appears to be connected with certain polynuclear phenols, and experiments were therefore performed with hydroquinone and pyrogallol, with a view to ascertaining how the laccol acted. In both cases oxidation was definitely proved to take place in the presence of laccol, though no such change occurred in check experiments without laccol. The hydroquinone was converted into quinone and water; thus—

\[2\text{C}_6\text{H}_4\text{OH}_2 + \text{O}_2 = 2\text{H}_2\text{O} + 2\text{C}_6\text{H}_4\text{O}_6\]

and pyrogallol was oxidised to purpurogallin, carbon dioxide being involved in proportion to the amount of oxygen absorbed. Micro-organisms were excluded by the conditions of the process adopted, and the existence of an oxidising diastase seems to be established ((Comp. rend., cxx, 266).

**Adulteration of Commercial Peptones.** L. Hugouneng, in the examination of some samples of commercial peptone, found two which reduced Fehling’s solution, and on further examination proved to contain about 33 per cent. of milk sugar. One of these samples bore the name of a firm of good repute, while the other emanated from a less known source. That the sugar present was lactose was confirmed by the examination of the oazone prepared from it. The total nitrogen of one of the samples amounted to 8.34 per cent., while a good sample of unadulterated peptone yielded 12.72 per cent. \((\text{Journ. de Pharm. [6], 1, 175})\).

**Phosphorus.** According to Dr. G. Pollacci, phosphorus is universally present in vegetable tissues, and is indispensable for certain vital processes. It is absent from the cell-wall, but present, in appreciable quantities, in the protoplasm, and especially in the chromatin granules of the nucleus. It occurs also in the hyphae and spores of fungi. In the vegetative organs of the higher plants it was found accumulated especially in the meristem and in the conducting tissues. The parts of the flower most rich in phosphorus are the ovules and the pollen-grains; the nucleus of the reproductive cells contains a much larger quantity than that of the vegetative cells. In seeds it is stored up especially in the embryo \((\text{Malpighia, 1894, pp. 361-379})\).
Poisonous Principle in the Cactaceae.

In Anhalonium levisii and in some other species of Cactaceae, Herr L. Lewin finds a poisonous alkaloid to which he gives the name anhalonine, resembling strychnine in its properties. It was found also in other species of Anhalonium, and in Mamillaria uberiformis, in Cactus fimbriatus and pentagonum, and in Cereus flagelliformis; while other species of Mamillaria examined were not poisonous. The formula of the chloride is given as \( \text{C}_6\text{H}_{13}\text{NO}_3\text{HCl} \) (Ber. Deutsch Bot. Gesell., 1894, pp. 283-290).

Syrop of Iodide of Iruz.

Ém. Bourquelot recommends a method of determining the amount of ferrous iodide in this preparation, which he describes as a modification of that contained in the U.S. Pharmacopoeia. It consists in adding excess of silver nitrate to the diluted syrup, and then determining the amount of silver unprecipitated, by means of decinormal solution of ammonium sulphocyanate. In discussing the subject generally M. Bourquelot gives a table showing the percentage of iodide of iron contained in the syrup of fourteen national pharmacopoeias, that of Buzenot containing the least, 0.92 per cent., and the Dutch most, 20 per cent.; the last being three times stronger than the former, while the German is ten times stronger than the French syrup (Journ. de Pharm., [6], i., 170).

Sucininate.

E. Aweng has investigated the constituents of that variety of amber known as succininate. This resin, which is produced in the stem and branches of Pinites succinifer, appears to be of both physiological and pathological origin. From 20 to 25 per cent. is soluble in alcohol, and consists principally of free succino-acetic acid, together with a small quantity of the same acid combined with borneol, representing probably the last trace of the volatile oil of the amber tree. By fusion with caustic potash succino-acetic acid is readily converted into succinic acid. That part of amber which is insoluble in alcohol, and has been termed succinin, proved to be insoluble in all the menstrua experimented with. Weak alcoholic solution of potash slowly decomposed succininate into succinic acid and a resin, succino-resinous. The only solvent that could be found for this body was a mixture of ether and alcohol; its formula was determined to be \( \text{C}_6\text{H}_{13}\text{O}_4 \). Other varieties of amber were also examined. Gedanite appears identical in composition with succininate; gelsema also resembles the latter, but contains a body resembling in colour carvol in the place of borneol; allingite on the other hand contains neither borneol, succino acid, nor succino-acetic acid (Archiv. d. Pharm., cxxxii., 660).

Saligenin.

Lederger suggests the use of saligenin in the place of salicin, on the ground that the former is in all probability the active constituent of the salicin, in which it is present to the extent of only about 43 per cent. By this means the organism would be relieved of the labour of splitting up the salicin into saligenin and sugar. Saligenin is the name given by Von Heyden's patient from carbolic acid and formaldehyde, but experiments are still wanting to show what its physiological action may be (Ther. Monatshefte from Med., Wochenchr., xli., 619).

Ferrpipry.

A new hemostatic and astringent has lately been put forward under the name of ferrpipry. It is a compound of ferrochloride and antipyrin represented by the formula \( \text{Fe}_{2}\text{O}_{3}(\text{C}_9\text{H}_7\text{N}_4\text{O})_2 \), and is obtained in the form of an orange-red powder yielding with water, in which it dissolves with facility, a dark red solution. It possesses excellent hemostatic properties, free from any causticity, and can be used either as a powder or in the form of a 20 per cent. solution, in all cases in which ferric chloride is indicated. Ferric pyrin may also be administered internally, in doses of 3 Gm., and may possibly prove valuable as an injection (Münch. Med. Wochenschr., xlii., 10).

Dermatol (basic gallate of bismuth) is said by O. Wiemer to be superior to all other antiseptics in inducing a clean union of the edges of wounds and not producing any inflammatory symptoms. Too indiscriminate use of the powder may, however, cause symptoms of bismuth poisoning (Therap. Monatshefte, ix., 15).

Aroil.

F. Á. Lüdy gives this name to an oxyiodo-gallate of bismuth. It is a tasteless greyish green powder, unaffected by light, but gradually decomposed by water or moist air. Though insoluble in the ordinary solvents, it dissolves readily in sodium hydrate solution and in dilute mineral acids. It forms an emulsion with glycerin and water, which does not decompose readily, can be made into stable ointments with soft paraffin or anhydrous wool-fat and also mixes well with camphor balsam. Employed in the state of powder it has been used with success in cases of ulcerated legs (Apot. Zeit., x., 63).

The Massee State and Magnetic Power.

Dr. Launcelot Andrews shows that, contrary to the general belief, the presence of moisture is not a necessary condition to the bleaching of organic colouring matters by the halogens, and concludes that the presence of any solvent whatever for either the halogen or the colouring matter would probably suffice to cause bleaching to take place. In the course of experiments bearing on the nature of the changes which occur when nitric acid is reduced to ammonia without production of hydrogen, he finds that whilst nitrates in alkaline solution are not reduced to ammonia by stannous hydrate, also in alkaline solution, yet the less stable nitrates are abundantly reduced. It is thought possible that a quantitative method for the separation of nitrates from nitrites, and the determination of the former, can be based upon the results of these reactions (Chem. News, lxxi., 80).

Low Temperatures and Magnetic Power.

R. Pictet has investigated the influence of low temperatures upon a permanent horseshoe magnet weighing 493.5 Gm., and formed of three pieces. When originally magnetised it had supported an armature weighing 4375 Gm., but in the course of years the weight it was capable of suspending was reduced to 3226.5 Gm. The effect of cooling the magnet thus formed had no effect on magnetic attraction. Thus, at a temperature of 30° C. this force was equivalent to 57-31 Gm., whilst at zero it was increased to 61-04 Gm., and at -105° to 76-64 Gm. (Comp. rend., cxx., 263).
THE CASTOR OIL TRADE AND SEED OF INDIA.

BY P. L. SIMMONDS, F.R.S.

This oil has made wonderful progress in British India, the chief seat of production. It is doubtful whether the plant is indigenous there, or if it is not rather a native of Africa.

There are three kinds of castor oil met with in commerce, that expressed from imported seeds in London, East Indian, and American. It would be difficult to define how much is used in medicine, because it has various other uses. It is employed for lubricating, as a lamp oil in India and China, for greasing steam engines, and in Siam for lubricating the steam rice mills. The Chinese have some mode of depriving it of its purgative properties, and use it for culinary purposes; hence it is largely employed in the Mongolian and Manchurian kitchens.

Castor oil is used by the Jews for their Sabbath lamps, under the name of "Kikli"; it gives a brilliant light and free from smoke.

The best medicinal oil is obtained by hydraulic pressure, the decorticated seeds not being subjected to heat. About 350,000 bushels of castor seed are grown yearly in the United States, and there were seven establishments engaged in pressing the seed, producing oil, according to the last census (1890), to the value of $650,000 dollars.

Castor oil is very little employed medicinally in China, as it does not purge Chinamen much. Newchwang is chiefly noted for the production of castor oil.

There are two main types of the plant. The one a tall tree, or small bush, and the other an annual.

Our imports of castor oil were in—

We imported from India in 1846 only 3815 cwt. of oil; in 1852 about 48,480 cwt., valued at 106,129; in 1866, 29,411 cwt.; it was then worth £2 15s. the cwt.

This dropped to about 21,000 cwt. in 1860, and to 19,013 cwt. in 1865, worth £49,379.

From 1850 to 1880 the Indian exports expanded from 100,000 gallons to nearly 3,000,000 gallons.

The distribution of the Indian castor oil since then has been as follows in the financial years ending in March:

From the above figures it will be seen that Australia, which took in some years one-third of the quantity produced, has dropped to less than one-half that amount. Other foreign countries keep pretty steady, and the British supply is about one half. But as a gallon of oil weighs nearly 10 lbs., it would appear that the exports of seed would have afforded over 4,300,000 gallons, so that in the last cited year India could have actually furnished nearly 7,000,000 gallons of oil, if all the seed shipped had been pressed there.

After the United Kingdom and Australia, the balance of Indian castor oil shipped goes to the Straits Settlements, Hong Kong, Mauritius and Ceylon, in quantities ranging from 80,000 to 250,000 gallons. That castor oil has felt the effect of the modern use of mineral oils as lubricants there can be no doubt, but the demand for the oil in the aggregate has not been seriously diminished.

The aggregate value of the castor oil, shipped from India, has not varied greatly in the last eight years; it has sometimes run up to £300,000; but, on the whole, more attention is given now to the shipments of the seed.

The value of the shipments of castor oil from India, taking the rupee at 2s., was as follows. The financial year, it should be noted, ends in March, not in December as with us:

**CUBERS AND ITS ADULTERATIONS.**

(Continued from p. 316.)

4. *Piper ribesoides*, Wall.—The fruit has a diameter of 7 mm., and the pedicel a length of 7-8 mm.; it therefore closely resembles the true cubeb, var. *crassipes*, De Wever, in size. It differs in its bitter, only faintly aromatic, but not burning, taste. Its chief histological peculiarities are the presence of rhombic crystals in the epidermal cells; the irregular arrangement of the hypodermal stone cells, which are sometimes in one row, sometimes in two or in small groups; and in the presence above the endocarp of large, crescent-shaped lignigenous lacunae, which have their upper surface more or less lined with stone cells, but few of these cells on the lower surface. The parenchymatous cells form three or four rows between these lacunae and the endocarp, but between them form about ten rows. The endocarpic cells form two or three rows, and are polygonal, with thick, porous walls, and enclose one or more large rhomboid, prismatic crystals. De Candolle has identified *P. ribesoides* with *Cubeba malicchii*, and it is interesting to note that the *Cubeba malicchii*, of Wallach's herbarium, has the structure here described as that of *P. ribesoides*, Wall. A specimen of *P. ribesoides*, of Falconer's herbarium at Kew, was found, however, to differ in having the endocarpic cells of an elongated prismatic form, and arranged in a single line. (Ph. J. [3], xxiii., pp. 121, 734.)

5. *Piper crassipes*, Korth. — A specimen in the Kew Herbarium, from Miquel, has been examined. Owing to the bad condition of the fruit, which would not afford a good section, it was difficult to see the structure clearly, but, so far as Dr. De Wever could make it out, it is absolutely identical with that of *P. ribesoides*. He does not appear, however, to have compared the leaves of the two plants.

The "*Piper crassipes,*" or large false cubeb of English commerce, is thus described:

A large, globular, brown or blackish fruit borne on a curved pedicel, usually at least twice as long as the fruit; the pedicel is not flattened, sometimes tapering, but never dilated at its free extremity. The fruit measures 7-8-8 mm., and the pedicel 12-33 mm.

The taste is bitter, but does not leave a persistent burning sensation in the mouth. Sulphuric acid gives with the crushed fruit a yellow coloration.

* AAbstract of paper by Dr. A. De Wever.

The structure of the fruit resembles that of *P. crassipes* and *P. ribesoides*, but the lacunae do not occur in the epicarp (Ph. J. [3], xviii., p. 269-270, Figs. 1, 2, 3).

6. *Piper sumatranum*, D.C.—The fruits examined were those in the Kew Herbarium from the collections of Heavy and Maingay, the latter having been determined by De Candolle. The structure in both was identical with that of *P. ribesoides*, they possess the same lacunae, and the endocarp is formed of irregularly prismatic cells.

7. *Cubeb with short pedicel.* — Dr. De Wever has found in commercial cubeb a *piper* with a short pedicel. The fruit is about 4-5 Mm. in diameter, and the pedicel 1 Mm. The fruits are feebly aromatic, but

Fig. 6.—*Pothomorphe molissimum,* have not a burning taste. They are characterized by a layer of small cells under the epidermis, like those of the epidermis, by a hypodermal layer of three or four rows of polygonal, uniform stone cells, and by the cubical cells of the endocarp being outined in horse-shoe fashion, i.e., the outside wall is thinner than the other three. In black pepper the reverse is
the case (Brunotte, 'Contributions à l'étude des Poivres et cubees,' 1889, pl. 1, No. 8).

8. *Piper mollissimum*, Bl.—This fruit is known as Keboe cubees; it is the *P. creasipes* described by Brunotte, according to Dr. De Wevre. The identification of the museum specimens belonging to the Society was made by Dr. Treub, at Mr. Holmes' request. The fruits are identical with specimens in the Kew Herbarium. The following description of them is given by Dr. De Wevre:

The fruits are much larger than those of the official cubees, blackish or greyish-black in colour, the surface is very wrinkled, the pedicel is about twice as long as the fruit, and is generally enlarged at the free end. The fruit is about 7 mm. in diameter, and the pedicel 16 mm. It has a very strong odour, different from that of the true cubee, and an acrid, slightly bitter and pungent taste, but does not leave the persistent burning sensation in the mouth which is occasioned by the genuine drug.

There is a hypodermic ring of stone cells which are polygonal in form, and are larger than those of cubees, and have a large cavity and few canals (Fig. 6).

The endocarp does not appear to be developed. There is a layer of compressed parenchymatous cells, and there is a zone in the position usually occupied by the endocarp, and formed of several rows of very compressed polygonal yellowish cells. The stem of the plant resembles that of *P. ribesoides* in having the structure of *Atrois* rather than of *Piper*, and judging from the histological characters of the whole plant, Dr. De Wevre thinks that Miquel was right in placing it in the genus *Pothomorpha*, rather than *Piper*.

The structure of the fruit differs from that of cubees in several particulars (Fig. 7). There are no stone cells in the hypodermal layer, nor in the endocarp. The seed coat is formed of two layers of cells (represented by one only in the drawing, through an error). The pedicels are similar in structure to those of cubees. Sulphuric acid gives a carmine red colouration with an alcoholic extract of the fruit. The fruit has a hot, biting taste, like that of pepper. It is about 4.5–5.5 mm. in diameter, and the pedicel is 5–6 mm., and often a little curved.

Fig. 7.—Fruit of *P. clusii*, transverse section.

9. *Piper clusii*, De C.—This fruit was found by M. Brunotte mixed with the official drug. It is sometimes imported from West Africa as a substitute for pepper.

Fig. 8.—Median vein of leaf of *P. lowong*, transverse section. The fruit is very like that of *Piper clusii*, but is a little larger; the pedicel is about 5–6 mm., and is thicker and flatter than in *P. clusii*. It has but little taste. With strong sulphuric acid the crushed fruit gives a brown colour tinged with rose.

10. *Piper caesianum*, A. Dietz.—More than one species seems to occur in herbaria under this name. The fruit examined was one from a specimen of the plant collected by Riedel, in Celebes, and now in the Kew Herbarium. The fruits are small, globular, distinctly mucronate, 5 mm. in diameter according to Miquel, and are furnished with a pedicel of about the same length. They do not much resemble cubees in appearance. The structure is like that of *Piper clusii*, but the epidermal cells are larger and the cuticle is thicker.

A specimen of a *Piper* in the Hanbury Herbarium, labelled "Sirie and-jiang" (*Piper caesianum* [?]'), shows a very different structure, and is, Dr. De Wevre believes, identical with the cubee figured by M. Brunotte, i.e. pl. 1, Fig. 8, with short pedicels (supra No. 7). A specimen forwarded by Dr. Treub to the Museum of the Pharmaceutical Society, and labelled "P. caesianum," appears to be identical with that of the Hanbury Herbarium. The section of the midrib of the leaf of Dr. Treub's plant is given.

(To be continued.)
deserves to remain so. The suggestion, for example, that the Pharmacopoeia should be converted into a students' text-book is no whit less absurd than that it should become a therapeutic manual. Mr. David Howard, in the fourth article of the series, deals with the official manufacturing processes, but here again we find only a re-statement of what has long been well-known and is bound to be acted upon, when the opportunity offers.

Surely, it is but a cheap and second-rate reputation that can be obtained by this system of suggestion. It has not even the little value attaching to the re-discovery of facts so frequent nowadays, and is particularly undignified in individuals occupying prominent positions. The Pharmacopoeia Committee and its official reporter may not be infallible in their methods and results, but they certainly appear more likely to turn out a practical Pharmacopoeia than the small host of their distinguished critics. It is not too much to say that the latter have not the least idea, beyond what is common knowledge, of what is required in a modern Pharmacopoeia, and all on whom the B.P. is binding as an authority will probably find that even a continuance of the old arrangement in its entirety is infinitely to be preferred to the product of a hybrid commission composed exclusively of amateurs, even though they be professional chemists or botanists, or medical practitioners who may be more or less ignorant of pharmacy. Even Dr. Stockman, in his otherwise sound and practical remarks at Edinburgh last week, endorsed Dr. Lauder Brunton's criticism with respect to cataplasma contii, apparently not recognising that the evaporation of the hemlock juice is necessary to drive off the alcohol, which, if left, might have an irritant effect. The whole tendency of the excellent discussion at the Edinburgh evening meeting is but to further confirm the opinion that pharmacists should be prominent in the compilation of all pharmacopoeias. Dr. Inglis Clark spoke of the need for aid from pharmacists to make the Pharmacopoeia meet the requirements of medical men, and wisely insisted that a more direct recognition should be accorded the former. Pharmacists ought to be able to feel that, in assisting in the compilation and correction of the Pharmacopoeia, they are exercising an undoubted right and not merely working on sufferance. It may be added, also, that preference should be given to "working" pharmacists rather than to ornamental members of committees, and that their position, like their work, should be second to none.

A HISTORY OF ORGANIC CHEMISTRY.

If pharmacy in the past has been the handmaid of medicine, it has equally been the nurse of scientific chemistry, and however much it may be customary in these later days for a certain class o
professional chemists to ancer at "pharmaceutical" chemistry, the fact cannot be overlooked that some of the leading chemists of their time have practised pharmacy during a portion of their career, and that the experience thus gained has probably invariably exercised a beneficial influence on their subsequent work. Amongst such eminent chemists must be classed CARL SCHORLEMMER, who, after receiving his early education at the Volksschule and Realaschule of his native town of Darmstadt, obtained a good grounding in mathematics and natural science at the Darmstadt Gewerbeschule, and, at the age of eighteen, became pupil to an apotheker at Gross-Umstadt. His connection with pharmacy continued for seven years, but he then came under the influence of BUNSEN at Heidelberg, and decided to follow the example of his school-fellow, DITTMAR, who had abandoned pharmacy for chemistry. SCHORLEMMER, therefore, attended KOPP's lectures at Giessen, where he also received systematic instruction in practical chemistry under WILL, and in 1859 he became private assistant to Professor Roscoe, at Owens College, Manchester. Later he succeeded DITTMAR as official assistant in the College Laboratory, and in 1874 he was appointed to a separate chair of organic chemistry, which he occupied until his death. Possessing a decided taste for the historical side of chemistry, he commenced a history of the whole science, but this remained uncompleted at his death. So early as 1879, however, he had published a work on the ' Rise and Development of Organic Chemistry ' (MACMILLAN and Co.), and this, after being long out of print, has recently been revised and re-published in English, under the editorship of Professor Smithells, who prefaces the book with an interesting and appreciative biographical notice, and thus renders it a peculiarly appropriate memorial to its author.

It has become so much a matter of habit to associate organic chemistry with the present century that it is quite necessary that SCHORLEMMER should commence by reminding his readers that facts of universal importance for chemistry were first observed in the case of organic bodies. Thus, vinegar was the only acid known to the ancients, and its name and the conception of acidity were expressed by the closely-related words—acet, acetus, vinegar, and ἀκρός, acidus, sour. Again, the first salts were prepared by acting on alkalies with vinegar, whilst the first reagent on record is infusion of nut-galls, paper steeped in which was employed, according to PLINY, to detect the presence of green vitriol (atramentum sutorium) in verdigris. Distillation, fermentation, and dyeing were all at first practised with organic substances, and numerous oils, fats, gums, resins, and other organic bodies were well known to the ancients. The rise and development of alchemy, however, resulted in greater progress being made in the study of inorganic substances, although the discovery of improved methods of distillation led to the discovery of essential oils and of alcohol. A few of the medical chemists of the sixteenth century endeavoured to extract from organic bodies their active medicinal principles, a large number of essential oils being thus discovered, whilst pyrolygous acid, acetum lignonum, was obtained by the dry distillation of wood, impure pyruvic acid (spiritus tartari) from tartar, impure acetone (spiritus ardens et saturno) from sugar of lead, succinic acid (fluo or sal succini) from amber, benzoic acid (flues benzoïna) from benzoïn, and, by the action of acids on spirit of wine, ether (oleum vitrioli dulce) and solution of ethyl chloride (spiritus solis dulcis) were prepared. During the seventeen and eighteen centuries, ROBERT BOYLE, NICOLAS LEMERY, STALI, SCHEEL, and others added considerably to the number of organic substances that had been scientifically investigated, the last-named being especially distinguished by his work on organic acids, glycerin, etc. BERGMAN, LAVOISIER, BERZELIUS, GAY-LUSSAC, GELMIN, and DUMAS followed with differing views regarding classification, and in 1828 WÖHLER performed the first synthesis of an organic compound, preparing urea from ammonium cyanate.

The historical account of the work since performed naturally occupies the major portion of the interesting volume under consideration. The inception, development, and progress or decay of the various theories that have been proposed from time to time are dealt with at length, the methods of organic analysis, calculation of formulæ, etc., receive proper attention; and the last three chapters record the synthesis of different organic compounds, whilst problems yet to be solved in the same direction are specified. These include the synthesis of morphee, quinine, sugar, gum, starch, and kindred bodies. No albuminous compound has yet been synthesised, and it is pointed out that this is essential for the solution of the enigma of life, and Kekulé's idea is thus expressed: "If ever chemists should succeed in obtaining albuminous bodies artificially, it will be in the state of living protoplasma." Finally it is shown that, in spite of the grand development of chemistry, probably even for that reason a survey becomes easier from day to day, and substances which cannot be arranged systematically will grow less in number in the course of time, as their constitution becomes known or as they become in some way connected with well-defined groups. Throughout the book the interest of the reader is consistently maintained, and individuals who have from any cause whatever conceived an aversion to the study of the chemistry of the hydrocarbons and their derivatives, would do well to make a special point of carefully persuing this volume, compiled by one who was not the least of the noble array of pharmacist-chemists.
THE LIQUEFACTION OF GASES.

Professor Olzewski’s claim to priority in respect to this work are now being championed by Mr. M. M. Pattison Muir, who attacked Professor Dewar in the columns of Nature, and was replied to by the Fullerian Professor in the same place. Last week, however, he returned to the charge, and concluded a long letter by asking for an instant and serious consideration of the whole matter brought forward, “by those who are truly interested in the advance of science.”

COMMERCIAL SCIENCE.

The British Medical Journal of last week presents a timely remonstrance against the growing tendency to prostitute progress in medical science to personal gain. It is pointed out that from time immemorial it has been the honourable tradition in this country “that every discovery made by a medical man, tending to the relief of suffering or the preservation of health, should be freely communicated to the world and placed at the disposal of the entire profession.” Dr. Hans Abelson, of Charlottenburg, however, has recently made application to Letters Patent in this country for a method of separating antitoxins from serum by means of metallic hydrates. This, it is urged, is both unprofessional and contrary to public policy, and the Government is asked to consider whether protection in such a case would be justifiable.

A UNIVERSAL LANGUAGE.

Medical practitioners continue to worry themselves about this “fad”; only a certain proportion of those who advocate a universal language for the profession recognising the fact that they are already assumed to possess a knowledge of a language which is practically universal. But the knowledge of Latin is more frequently theoretical than practical, and there seems to be a disinclination to master its intricacies. It may be suggested that English is well on the way to becoming the universal language, and that those who now practise it might do well to obtain a thorough knowledge of it. The result would be much more profitable on the whole than an imperfect acquaintance with several ancient and modern tongues.

BENEVOLENT AND ORPHAN FUNDS.

We are asked to publish the following corrections in the lists of contributions to the above funds:—

Benevolent Fund: H. Hopkinson, Grantham (left out). Dr. T. L. Williams, published under Newcastle-on-Tyne, should be Newcastle, Staffs. Orphan Fund: George Cooper, Bransome, £10 10s.

THE ANNUAL DINNER.

A meeting will be held at 17, Bloomsbury Square on Wednesday next, March 13, at 11.30 a.m. precisely, for the purpose of making arrangements for the annual dinner of the members of the Pharmaceutical Society and their friends. The President will take the chair, and gentlemen interested in the annual gathering are invited to attend.

Proceedings of Societies in London.

CHEMICAL SOCIETY.

A meeting was held on Thursday, February 21, 1896, the President (Dr. Armstrong, F.R.S.) in the chair. The President read the names of the new officers for the ensuing year as proposed by the Council: as President, A. Vernon Harcourt, F.R.S., in place of Dr. Armstrong; as Vice-Presidents, Professor Japp, F.R.S., and Professor Roberts-Austen, F.R.S.; as members of the Council, in place of the retiring members, Professor Benson, Messrs. B. H. Brough and O. Hefner. Professor MacLeod, F.R.S., Messrs. Bevan, Voolker, and Blount, were elected auditors.

The following papers were read:—

THE ELECTRO-MOTIVE FORCE OF AN IODINE CELL.

BY A. F. LAURIE, M.A.

The object of this investigation was to discover if any relation existed between the E.M.F. and the amount of iodine present in solution, and, if so, if this fact could be utilised for determining the co-efficient of diffusion of iodine into such a solution. No reliable results could be obtained when platinum wires were used in contact with a solution of potassium iodide, as the E.M.F. varied, and no concordant results could be obtained under apparently similar conditions. When a trace of iodine, however, was added to the solution, concordant results were obtained.

It was found that for solutions of iodine, of strengths from 1 in 1,000 to 1 in 10,000, the E.M.F. varied according to the strength of solution.

A cell was now used consisting of a platinum wire sealed in a tube containing iodine solution, which diffused into potassium iodide solution, in which the zinc plate was immersed. By measuring the E.M.F. between the zinc and platinum poles at different periods, and plotting the results as a curve, the co-efficient of diffusion may be calculated.

The chemical action in the cell consists in the solution of the zinc and formation of zinc iodide; the iodine is set free at the platinum pole, and the zinc dissolved in the excess of iodine.

These experiments are only preliminary, but the author hopes to utilise the method for determining the co-efficients of diffusion of other substances.

CONTRIBUTIONS TO THE CHEMISTRY OF CELLULOSE.

BY MESSRS. CROSS, BEVAN, AND BIDDLE.

Cellulose is a very inert substance towards most chemical reagents, and in many of these changes can be recovered by regeneration as cellulose, showing that no alteration has taken place in the molecule, e.g., that it has not suffered hydrolysis.

By certain synthetical reactions, however, some insight has been gained as to the constitution of cellulose. From the formation of certain esters, as nitrate, acetate, etc., it was supposed that it contained three hydroxyl groups, since it yielded tri-nitrates, etc. In order to investigate the action of acetylating agents on cellulose, the pure substance was first treated with zinc acetate, when a dry powder was obtained. This
reacted with acetyl chloride, and yielded a tetracetate of cellulose, \( \text{C}_6\text{H}_5\text{O} (\text{OC}-\text{CH}_3)_4 \). This tetracetate was a true cellulose derivative, since it could be made into a film, and on saponification with potash it yields a pure continuous cellulose. The nitrate has also the characteristics of continuous cellulose, and may be spun into fibres.

From certain reactions, it may be assumed that cellulose acts as a salt, in various dyeing operations, and forming probably a double salt with zinc acetate as mentioned above. Now if pure cellulose moistened with pure water be placed between two poles of a battery and a current passed, there is a passage of metal from pole to pole, and this metal remains in the substance of the cellulose. In this way silver and copper have been deposited in sheets of cellulose.

It is proposed to classify the celluloses under three headings, according to the percentage of contained carbon, the furfural yield, and their reactions.

<table>
<thead>
<tr>
<th>Percentage of carbon</th>
<th>Furfural yield</th>
<th>Reactions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cotton group.......</td>
<td>44 p.c.</td>
<td>2 p.c.</td>
</tr>
<tr>
<td>Jute group.........</td>
<td>43 p.c.</td>
<td>4-6 p.c.</td>
</tr>
<tr>
<td>Cereals ............</td>
<td>42 p.c. or 12-14 p.c.</td>
<td>loses</td>
</tr>
</tbody>
</table>

The celluloses are probably not true pentosans but probably complex heaxes. By germination of certain seeds in nitric acid of different strengths it was found that the furfural yield increased as the strength of the acid increased in which germination occurred. By taking cereals grown as starvation or full crop, and analysing them, the furfural yield in each case was found to be the same.

**Melting Points of Mixtures.**

**By Holland Crompton, M.A., and Miss Whiteley.**

In this investigation the author examined the melting points of mixtures in order, if possible, to apply the laws of solution. When solidification occurs, one of the substances solidifies, leaving the other in the liquid condition.

The following formula should hold

\[
\log s = \rho \cdot \frac{T - T_1}{T_1}
\]

where \( s \) = number of molecules of substance in 100 molecules of solvent, \( \rho \) = latent heat of fusion, \( T \) and \( T_1 \) are temperatures (in absolute units) of fusion of substance and solvent. Now for a compound the author has previously shown that

\[ \rho = 13.28 \cdot 3vT \]

where \( v \) is the valency of elements in the compound.

It was found that the melting points did follow this formula, though they generally obtained results too high from those calculated. This they attribute to the fact that the substance separating out as solid is not pure but contains a trace of the solvent.

**The Volumetric Determination of Manganese.**

**By J. HEDDOP and H. RAMAGE.**

The method generally followed for the volumetric determination of manganese is to dissolve the ore in nitric acid, and add peroxide of bismuth, when the manganese is oxidised to permanganic acid, and then titrate with hydrogen peroxide. An improvement in this method is as follows: the ore is dissolved in dilute nitric acid and sodium bismuthate added, and the whole run into a known amount of hydroxyl peroxide, which is then titrated back with standard potassium permanganate.

In this way very rapid and accurate results are obtained, sodium bismuthate \( \text{NaBiO}_3 \), acting as a very powerful reducing agent.

The following papers were taken as read:—

"Bromocamphoric Acid, an Oxidation Product of Bromocamphor," by Dr. Kipping.

"Note on the Action of Diastase on Cold Starch Paste," by H. Brown, F.R.S., and Dr. G. H. Morris.

"Magnetic Rotation of Some Oilsines," by Dr. W. H. Perkin, F.R.S.

**Cheirmists' Assistants' Association.**

At the meeting held on Thursday, February 21, the following paper was read:—

**Diatoms.**

By F. Ransom.

The subject which I propose to bring before your notice is, I fear, but remotely connected with the theory or practice of pharmacy. The interests of the educated pharmacist are not, however, confined to the matters which immediately concern his profession; many members of our calling find the pursuit of some branch of natural history an attractive form of recreation.

Of the various departments of botany there are probably few which provide more interest for the collector and for the student in botanical physiology than the study of diatoms. The number of recorded species is constantly increasing, there are points connected with their life history of exceptional interest, and they provide some of the most beautiful objects which are to be found in the microscopist's cabinet.

The main characteristic of a diatom, which at once distinguishes it from all allied unicellular organisms, is the presence of a hard framework of silice which appears to be intimately associated with the cellulose of the cell-wall. This shell is all that is usually seen in mounted specimens, the organic constituents having been previously removed by means of acids or other solvents. The contents thus removed as interfering with the delineation of the delicate markings of the shell, correspond to a large extent with those usually found in a young vegetable cell. The entire cell, or frustule as it is termed, is surrounded by a thin glistening envelope, which is invisible until stained with some reagent.

Diatoms, in considerable variety, being everywhere abundant, offer to all who are interested in the study of the minute forms of life, exceptional opportunities for observation. In every sea or river, pond or ditch, in fact, in almost every place where water has remained for a few days exposed to light and air, di-
atoms are to be found in greater or less abundance. Even amongst moss and on the surface of damp ground they may frequently be discovered. If some of the brown deposit which is often seen attached to any smooth surface washed by running water be carefully removed and placed under a microscope, it will be found to contain large numbers of these minute organisms, if, indeed, it be not entirely composed of them. They can generally be detected amongst other bodies present by their symmetry of form and the more or less evident markings on their silicious shells.

Although comparatively recently discovered, probably few families of the vegetable kingdom have had a more eventful history as recorded by their different observers. Their minute size, together with the imperfections of the instruments used in their examination, and the very uncertain and often erroneous biological ideas held by their early observers, concealed for a long time their true position in nature. According to Ehrenberg, the great German naturalist of the beginning of the present century, diatoms were discovered early in the eighteenth century, and the first undoubted illustration occurs in the "Philosophical Transactions of the Royal Society" for 1703.

In 1745 William Arderon described what he terms the "oat-like animal," evidently some species of _Navicula_, a genus of diatoms, associated with the "hair-like insect," as he designates the _Oscillatoria_. The most evident reason for thus placing in the animal kingdom the representatives of these two families, which are now regarded as undoubted plants, was the power that both possess of individual movement, apparently quite independent of any exterior agency. A more extended knowledge of plants has clearly demonstrated that motion of this description is not confined to animals, but is frequent amongst the lower forms of vegetable life.

At the beginning of this century much confusion existed, and the _Navicula_ were regarded as one stage in the life of the _Oscillatoria_. Shortly afterwards a remarkably bold observer (ingenious) maintained that in certain forms, at least, their characteristics were not sufficiently defined to warrant their being placed either amongst animals or plants, and he considered that their true position was in the mineral kingdom. Such degradation, however, was not long maintained, for in 1816 we find a distinction being made, some species being regarded as animals and others as plants. De Candolle and some other observers correctly regarded the whole family as plants. About the year 1822 Bory de St. Vincent, being unable to satisfy himself in placing several of the lowest forms of life amongst animals or plants, created a sort of intermediate organic kingdom, which he called _Artrosideae_, in which many diatoms were included. In 1831, Ehrenberg remarks that he had succeeded in establishing their place in the animal kingdom, and they are thus classed in his valuable work on the _Infusoria_. Here they appear to have remained undisturbed for some time, but gradually as general biological knowledge advanced, and as observers had more efficient microscopes at their disposal, doubt began to arise, until in 1853 the Rev. William Smith in his standard work "A Synopsis of the British Diatomaceae" unhesitatingly classifies the whole family as a natural order in the sub-class Algae of the vegetable kingdom. Quite recently an attempt has been made by Cunningham, an American observer, to prove that diatoms possess the characters of Protosor, and should consequently be classed as animals. He relies largely on observations connected with their movements, which, he considers, show some indication of volition. These observations, or at least the deductions from them, are not likely to be confirmed, and there is little doubt that they will be allowed to remain in the comprehensive group of Algae. The desmids have frequently been classed with diatoms, but the absence of the silicious shell and other important differences have now caused them to be placed in a separate order. Thus we find that during their comparatively short existence in the domain of science, diatoms have been allotted to each of the three kingdoms, and have also for a short time been placed in a fourth, which was brought into existence largely for their accommodation.

Having briefly reviewed the history of the Diatomaceae, it will be well to enter more fully into their structure. Each cell is either free, attached to one or more of its species, fixed by a stipe to some foreign body, or enclosed with many others in a long gelatinous tube. Each frustule is seen to possess two valves, placed together in a position somewhat similar to a closed bivalve shell, but instead of being closely attached they are connected by two silicious hoops, one fitting closely into the other. Within the frustule is found a yellowish-brown, or occasionally green, colouring matter or endochrome, which is similar to the chlorophyll of most plants, and evidently capable of performing the same functions. Diatomine was the term employed by Nägeli to indicate this colouring matter, which he wrongly considered to be a simple compound. It appears to consist of true chlorophyll associated with certain yellow coloured principles, which are not usually present in green plants. The colour of the so-called diatomised is readily changed to an emerald green by the application of heat, alcohol, or acids. On adding chloroform to a dilute alcoholic solution, Petit found that on separation the whole of the yellow colouring matter was left in the hydro-alcoholic solution, while the chloroform was coloured green by a substance which produced the absorption spectra characteristic of chlorophyll, and with which it was probably identical. Some extraordinary instances have been given of the apparent power of this endochrome to resist decomposition. Brunn relates that some diatoms which he had collected in the Sahara, and kept in the water in which they were found, preserved their endochrome in an unaltered condition for four years. The same authority also states that he had seen fossil diatoms from a large deposit in Holland, and which must have been buried for centuries, present occasional specimens in which the endochrome was still yellow, although it had become somewhat thicker and more plastic.

The protoplasm which is present in the frustule remains invisible until coloured with some special re-
agent. It is then seen attached to the shell, occupying a position similar to that of the primordial utricule in most vitally active cells, and extending in the form of channels to the centre, where the nucleus and nucleolus may be distinguished. Unlike the great majority of plants, diatoms are believed to contain no starch. It is possible that traces may be discovered, but if present the quantity must be exceedingly small. There are also usually present minute oily globules which are found in various parts of the frustule. It has been suggested that these globules take the place of the starch grains frequently met with in coniferous Algae. On drying and heating, a peculiar odour is emitted which has been ascribed to this oily constituent. The remainder of the interior is occupied by water, a current of which is continually passing through the frustule. The water is charged with carbonic acid, which is decomposed in the process of assimilation, the carbon being retained and the oxygen liberated. This oxygen, being less soluble than the carbonic acid, may frequently be seen rising in bubbles to the surface of the water wherever there is any large aggregation of diatoms below. This power of liberating oxygen affords one of the strongest reasons for placing the order in the vegetable kingdom. Various compounds dissolved in the water are also retained for use, including silicic acid that is required for the construction of the valves, and nitrogen compounds for the formation of protoplasm.

(To be continued.)

Scottish Transactions.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

The fifth meeting of the seventeenth session was held in the Pharmaceutical Society's Hall, 36, York Place, Edinburgh, on Wednesday, February 29, at 9.15 p.m., Mr. Alexander Sutherland, President, in the chair.

The minutes of last meeting were read and approved.

The Chairman said he would take this opportunity—the first time the Association had met in the new Hall—to express on behalf of the Association the generous way in which the Council of the Society had always treated the Association, and the kindness of the North British Branch Executive in making such arrangements for their comfort and convenience in holding their fortnightly meetings.

The following paper was then read:

THE PROFESSION OF PHARMACY FROM AN APPRENTICE'S STANDPOINT: BEING SHILOHIONS FROM THE DIARY OF AN APPRENTICE.

BY W. MAKERPHONE LITTLE.

Though this title be somewhat long, and may appear somewhat bombastic, yet, after mature consideration, I came to the conclusion that the subject in all its grandeur required these few words to express exactly what is implied. I am aware that the usual run of apprentice communications to this Society partake more of the nature of reading something which may or may not be pharmaceutically of interest to its members. But, be it understood, it is for this very reason that I introduce the present effort, as a kind of general "pick-me-up," a reviving draught, after the night or two of chemical and pharmaceutical notes to which this Association has had the pleasure of listening. And, be it understood, also, that I treat it in the highest possible spirit, for, although I have had this diary in my hands for some little time with intent to make use of it, I have not been favoured with an opportunity to present it to you.

Now that the opportunity has come, I feel astonished at my temerity in producing it, but, needless to say, I rely wholly on the indulgence of those now before me. The story is told by the author, in my words, however, and when the pronoun "I" is used, I expect you to understand that the author is meant, and not your humble servant. Having executed this preluminary cantor to your satisfaction I hope, let me now proceed to the more serious business.

"I," says he, "having received a first-class education, in the scope of which figured Greek, Latin, Geometry, Trigonometry, and various other accomplishments, was duly apprenticed to a chemist and druggist, and having got through my first morning's dusting, which I relieved not, was told off to wash a few gross of greasy, filthy, evil-smelling bottles, and to hold myself in readiness at a moment's notice to convey certain mysterious packages and some few syphons of aerated waters to customers of the establishment. Pegging away manfully at my work, I washed a dozen or two with but indifferent success, and was anything but relieved to hear my new master's voice, saying in tones certainly neither sweet nor pleasant, but varying in modulation, like the strains of a penny tin whistle, 'Bring half-a-dozen syphons of soda, Cornelius (for my name is Cornelius), and be quick about it. Mind, now, make no mistake, but carry them smartly to Mrs. Collodion Flexile, just round the corner. And now be off.' I, therefore, never before having converted myself into a hewer of wood or a carrier of waters, very naturally visited my just indignation on the message boy, whose bounden duty the fulfillment of whose offers I rightly believed to be. However, screwing up my courage to the desired point, and hoping against hope that Mrs. F. did not live far away, I bravely snatched up the syphons, departed on my little sortie, but found from the numbers on the doors that 'my lady' lived at the extreme end of the terrace. Here was I, then, with a syphon in each coat pocket and two in each hand—a kind of light porter, in fact—trudging along to Mrs. Collodion Flexile, who lived fully three-quarters of a mile away. Also I fickle fortune, who did I see but my God-mother, Lady Turmeric, driving past in her carriage. I tried, oh! how I tried to escape observation, but was detected in the very act. True to my gentlemanly instincts and up-bringing, and manipulating the syphons as best I could, I deftly uncovered my head, when crash! crash!! bang! I went three syphons on the pavement, while I, the indurated apprentice, or rather the articled water-carrier, stood thunder-stuck, gazing on my handiwork. Then, crashing back a sob, I resumed my journey, delivered the full syphons,
received empties, and walked back to the shop, brood-
ing over my sorrows. My master, who, to tell the
truth, acted very much like a raving maniac, said it
was perfect nonsense and downright carelessness, but
what vexed me most was being called a liar, for he
said that my story was a mere fabrication of trumped-
up falsehoods. Of course, he knew best, being older
than I, and consequently having more experience in
the ways of the world. I did not chronicle any more
that day.

"Such small escapades as these served to make the
first months of my apprenticeship very dull indeed,
and sure it was no wonder, for, on account of the
many hard words which were slung at me from time
to time, with more or less coarseness, nearly all that
essence of vitality and that exuberance of spirit, both
of which are so essential to youth, were slowly, steadily,
and surely being crushed out of me. However, and
in all justices to my superiors do I say it, I managed to
pick up a knowledge of those little details which fell
to my lot during my first year's apprenticeship, such
as putting up powders, learning to weigh substances
and measure liquids accurately, making pills, oint-
ments, and suppositories, all with tolerable speed
and correctness. Also, I might mention, again in due
justice to my employer, that I learned to clean greasy
ointment slabs, resinous and gummy mortars, and a
multitude of other menial occupations too numerous
to mention. This, then, was my work from day to day,
week to week, and month to month, with the excep-
tion, however, of a weekly window-cleaning-day, in
which I, though new to the mysteries of whitewash
and chamois leather, was forced by circumstances to
share.

"While I was busy with the large sheets of glass,
rubbing them to the best of my ability, the questions,
'Is this pharmacy?' 'Is this the work of an appren-
tice chemist?' kept constantly recurring to my mind.

"The ultimate conclusion at which I arrived was
that, the chemist's profession like croton-chloral-
hydrate is 'wrongly so-called.' Not being able to
polish the immense panes to my master's satisfaction,
at which you can scarcely be surprised, he launched
at me a long and exhaustive torrent of invective
and abuse; indeed, to put it plainly, he called me a fool.
The proverbial boot-jack would even have been prefer-
able to this, for I might have dodged it, but what
caused me most pain and gave me a very sore and
almost bursting heart was the fact that the assistant,
who, up to this time had looked upon me with a feeling
akin to contempt, took advantage of our master's
temporary absence to discourse freely with me about
what he called my 'thinking too much of myself.'
Thinking too much of myself, indeed! Well, well, it
is hard that one should be misunderstood! He, when
an apprentice, had gone messages, wheeled hand-carts,
cleansed windows and washed bottles, but he did not
for one moment consider the difference in our social
position, and that it was infinitely more humiliating to
me than to him. All these aforesaid items he enumer-
ated with a very evident relish, well knowing that
by this means he would cut me deep, yea, even unto
the core. Whatever he had done was not too much
to ask an insignificant apprentice to perform. These
were his concluding words, but to all those wounds
and stings, I applied antidote of 'Golden Silence.'
Thus did I pursue the even or rather uneven tenor of
my way, gaining knowledge en route, but at the
same time devoutly wishing that I never had been
born. However, in justice to my employer, let me say
that I could read and dispense prescriptions in a
very fair way. I could also, thanks to him, make my bow
and my scrape to his customers, converse freely with
them on current topics, and could make myself
generally useful. Four whole years had now rolled
over my devoted head, during which time I had per-
formed many odd jobs, in fact, become a jack-of-all
trades and master of none. Thanks be to him, I
handled the saw and drove in nails like a carpenter;
I plied the needle like a dressmaker; I repaired broken
pipes and performed dirty, offensive work like a
plumber; I swept the floor and lit the fire like a house-
maid; I washed bottles, slabs, mortars, and various
dishes like a scullion, and dusted like a washerwoman—
comprising all these occupations, mark you, under the
guise of an apprentice chemist. Woe worth the day,
woe worth the hour, when I parted company with my
self-respect. Little did I think that I, when I entered
the so-called magnificent profession, should be thus
cast down into the depths of despondency and despair!
Oh, the natural unfitness of things. Much as it relieves
my feelings to let off steam in this manner, never, oh,
ever, shall this diary reach mortal eyes other than
mine.

"Another feature of the business of the self-styled
professional gentlemen is the sale of such articles as
combs—both small teeth and large—brushes, tooth
brushes, nail brushes, and last, but not least, those
abominable cigars. Why a person must serve an
apprenticeship to sell these things is entirely beyond
my comprehension. Perhaps the qualification of being
a professional shopman may in some measure account
for this? I do not know, though, and care still less.
I am heartily sick of the whole business. A mad frenzy,
both of despair and sorrow, seizes me even now as I
write. As the truth is slowly forced upon me that the
last year of my apprenticeship has drawn to a
close, I realise that I am a done creature. All plea-
sure and light has died out of my life, backbitings and
scoormings have embittered my existence. No succour
at hand, no respite near, I am dragging out in soli-
tude the wretched remains of a thoroughly wasted
life. I see before me the phial of morphine solution
which shall so soon rescue me from this purgatory.
I have it in my hand, I am toying with it. Alas, God
help me, I have swallowed the contents. May mercy
be shown me hereafter, as it never was here. I have
little time to write more, but before I fall into that
pleasant somnolent state due to the effects of opium,
let me express one wish, that the all-familiar legend
be inscribed on my tomb. . . . Regniesseract in Pacce.
In life I was miserable, in death I am, if not happy, less
miserable than before. Farewell!"

Thus, then, ends the diary. Let me ask your
attention for a few minutes more in order to add a
few remarks of my own, and to offer an explanation
as to why you have heard this gruesome tale of woe. The young fellow whose summarised life you have just heard was an intimate friend of mine, and after his decease, the causes of which were hushed up as much as possible, his immediate relatives presented me with his diary as a remembrance of him who has departed this life. The medical expert in attendance informed me that after partaking of the fatal draught, my friend was seized with drowsiness, drowsiness gave place to giddiness, giddiness to stupor, stupor to insensibility, his breathing became hard and heavy, his pupils became contracted, his pulse feeble, coma and convulsions resulted, and death ensued. Considering, therefore, the manner of his death and the primary causes of it, I, notwithstanding his intention that the diary should never reach mortal eye, have presumed to convey it to your ears, thereby violating the wishes of the dead. But for this breach of friendship I hope to receive pardon, knowing that a lesson, however weak, is not without its good results.

But let that pass. I can quite well believe that what you have just heard is in some parts a little overdrawn, but I can just as well credit a great portion with truth, and that pretty strictly. Let me venture to say, and I can almost hear my heart beating as I say it, that "it's not exactly what master says, but it's the nasty way he says it." A little more kindness, a little more forbearance, a word or two of judicious praise, and a little less of the commanding and exasperating tone would all be valuable adjuncts to ensuring a successful, conscientious, and hard-working apprenticeship. And you assistants, too, be not ever ready to abuse the little authority with which your master entrusts you. Remember that you yourselves were once apprentices, and visit not your wrath upon those under you; simply because you had to stand it. No, be kind, and a model establishment will result. And you apprentices who intend to follow out the business, bear all these things in mind, and beware, for you are the next generation of assistants and masters. Conduct yourselves properly—speaking, acting, and thinking; stand on your dignity as gentlemen, and all will be well.

One word more and I am done.

Without doubt we have all—all, I say—as apprentices, been forced to perform many operations, of which window cleaning and washing bottles are but types, and if these menial occupations are to form a basis of a general standard of excellence, of what use might I ask is it necessary, necessary, bear in mind, to introduce into the scope of the Preliminary examination higher mathematics and the classical languages. As Mr. Hill very nicely put it, it would be advantageous; but would it be essential? Applying the same argument still further, it certainly would be advantageous to know how to clean bottles, but is it essential, or should it be so in the chemist's business? Again, in what position is an apprentice (an average one, I mean) when he has finished his time? He has learned the art of dispensing physicians' and surgeons' prescriptions, and that of washing bottles. Both of these are great privileges, especially the latter—at least, so we, as apprentices, are told. Why should it be? During his apprenticeship he has had no time for study, for what youth has the fortitude to study after twelve hours' work and drudgery. How then can he pass his Minor? By taking classes, you say. Yes, perhaps so, but in some cases the wherewithal is not forthcoming. What then? No, no, before trying to raise the standard of the Preliminary, with a view to introducing a better class of apprentices into the trade, for at present it is nothing else, raise the present apprentices from the state of disgust and apathy into which their duties plunge them by purging the so-called profession of its defects. By employing the proper class of individuals for menial work, healthy and permanent good would undoubtedly result to the business.

Then, and not till then, will chemists be justified in advertising for an apprentice to follow the profession of pharmacy.

The reading of the paper was followed by a discussion, taken part in by Messrs. Cowie, Hill, Lock, Mackenzie, Sutherland, and Thwaites, the general opinion being that while the conditions of apprenticeship were too frequently highly unsatisfactory and as a rule capable of much improvement, especially in regard to time for study, many of the so-called menial duties named by the author formed an essential, though perhaps unpleasant, part of a complete training in practical pharmacy.

The next paper was a—

NOTE ON LINSEED MALT.

BY ALEXANDER J. DRY.

The author said he had been unexpectedly prevented from completing his work, and could now offer a few preliminary observations only. He was engaged in the examination of eighteen samples of meal obtained from grocers and chemists. It was noteworthy that in most of the best class grocers' shops he was told they did not keep linseed meal, and was referred to the nearest chemist. The yield of oil from the samples varied from about 5½ to 36 per cent. Only one sample indicated presence of starch. With one exception the chemists' samples appeared of excellent quality, but those obtained from grocers, though often yielding the full percentage of oil, were coarse and inferior. He intended to suggest characters and tests which might be introduced in the new Pharmacopoeia. He hoped to finish the work and have something more definite to say at a later date.

In the discussion which followed, Mr. Cowie said many medical men preferred the old crushed oats, and he thought its use should be made legal.

Mr. Rutherford Hill then performed some so-called "Backshop Experiments," illustrating, among other things, the fact that a chemist must necessarily have a good eye for colours.

On the motion of the Chairman, votes of thanks were awarded to the authors of papers and to Mr. Hill.
GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

At the meeting held on February 7, the following paper was read:—

NOTES ON THE REVISION OF THE BRITISH PHARMACOPEIA.

BY GEORGE LUNAN.

Acetaminilum.—The maximum dose should be up to 4 grains. In B.P. addenda it is 10.

Acidum Carbonicum.—The melting point should be raised to 38° C. at least, possibly 40° C. is commercially attainable. There should also be inserted under tests a quantitative determination of carbonic acid. The valuation introduced in U.S. Pharmacopoeia works very well. The process consists in combining the sample with a weighed excess of bromine and titrating with volumetric sodium thiosulphate after the solution has been treated with excess of potassium iodide. The purity of phenol is approximately determined by loss of free bromine.

The liquefied carbonic acid requires 12½ per cent. of water, not about 9, as at present, to keep permanently liquefied. The addition of spirit as suggested by Boe may meet the difficulty and retain the same strength. It would be better to have the finished product contain exactly 90 per cent. of carbonic phenol, or a definite eighth of water added. On the whole I favour the latter course.

Acidum Hypophosphorum.—The increasing use of hypophosphorous acid warrants its inclusion in the new Pharmacopoeia. The process of manufacture need not be stated, provided full tests for its purity be given. The stronger acid, containing 30 per cent. P↓H↓p↓O↓, and having a specific gravity of 1·367, is to be preferred. The acid should be free from sulphates, oxalates, barium, and calcium, should not respond to tests for phosphates and phosphates, and should be determined by sodium hydrate or permanganate standard solution. Failing a pure acid than the present processes produce, it will have to be obtained by decomposition of lead hypophosphate with H↓2↓S.

Acidum Lacticum et Acidum Lacticum Dilutum.—It is, I venture to suggest, confusing to have two strengths. My experience is that it leads to confusion of prescribers, who frequently write “acid lactic” when they mean their patient to get the diluted preparation, the lactic acid of P.B. which has dose stated. Besides, the demand does not justify it occupying so much space. The acidum lacticum should remain in P.B. and have the dose attached—5 to 20 minims, the other should be deleted.

Acidum Moronii et Liquor Morphinae Bimeconati.—It is doubtful if these have justified their inclusion. As far as I have formed any opinion it is opposed to retaining them.

Acidum Salicylicum should have melting point raised to 150° C.

Amyl Nitris.—The dose “In mixtures to be swallowed” is stated at “from ¼ minum to 1 minum.” I have frequently dispensed it up to 2 minims, and am assured that that dose is quite safe. Is it not possible that this may be due to prescribers having experience of old and deficient samples?

Amyl Nitris.—Dose ½ to 1 grain. I have twice dispensed prescriptions with 5 grain doses.

Armoracia Raddis et Spiritus Armoracia Compositus should be omitted. There are many unofficial drugs and preparations in more frequent use, and the fact of their inclusion in 1864, 1867, and 1885 P.B. gives all the reference their use requires.

Bebeerina Sulphas should be deleted. It has appeared in the 1864, 1867, and 1885 Pharmacopeias, and it is time it was relegated to the place of an old official preparation.

Belae Fructus.—This should give way to another drug, whose properties are definite and assured.

Bismuth Chloridum et Bismuthi Salicylas.—Both oxysalts are likely aspirants to pharmacopeial honours. They have advantages over the official bismuth salts for certain cases, and are in frequent request. The former, an oxysalt, as all official bismuth salts are, has the formula B↓2↓Cl↓.↓O↓, and is readily obtained by pouring solution of bismuth chloride into water. On account of this salt having been long in the market in a very impure condition as a cosmetic, “pearl white,” “blanc de pearl,” it will have not only to be safeguarded with all the bismuthum purification tests, but carefully examined when taken into stock. The maximum dose of all bismuth salts save the oxide and salicylate should be raised to at least 60 grains. I frequently dispense without question two drachm doses of subnitrate.

With regard to the oxysalicylate of bismuth, great difficulty is experienced in preparing a pure salt.* Dott has pointed out that samples should yield on ignition 61·31 per cent. of oxide, and not more than a trace to other (absence of free salicylic acid). The present supply require careful examination for free salicylic acid and bismuthyl chloride (bismuth oxychloride) and bismuthyl nitrate. Dose, up to 30 grains.

Caffeina Citras should be caffeiuna citrata, citrated caffeine, not citrate of caffeine.

Caffeina Citrata Effervescent.—An official formula for this preparation is required. The following makes a very good preparation.

Take of—

<table>
<thead>
<tr>
<th>Substance</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Citrated caffeine</td>
<td>4 parts</td>
</tr>
<tr>
<td>Bicarbonate of sodium</td>
<td>46</td>
</tr>
<tr>
<td>Tartaric acid</td>
<td>24</td>
</tr>
<tr>
<td>Citric acid</td>
<td>18</td>
</tr>
<tr>
<td>Refined sugar</td>
<td>10</td>
</tr>
</tbody>
</table>

These granules contain rather over 4 per cent. of citrated caffeine—no allowance being made for evaporation from citric acid. The sugar is necessary to give the preparation a similar taste to the unofficial preparations (containing from 1 to 5 grains in drachm) so frequently prescribed. Otherwise it is no advantage. The dose 3i. to 3ii. The U.S. Pharmacopoeia formula contains one per cent. of

* Pharm. Journ., p. 588, No. 1291.
cafeine, and the bulk is made up of equal parts of bicarbonate of soda, tartaric acid and sugar, which, after being dried together, are granulated by moistening with alcohol, the granules dried, and reduced to a coarse granular powder.

_Camomilla Cortex_ should be omitted as well as vinum rhbc., the preparation for which it is required.

_Cataplasmata._—On the whole I think these might now be omitted. No doubt it is well to be able to give directions for preparing poultices of varied substances, but the Pharmacopoeia need not contain more than a type, say cataplasmata lini. This would entail the deletion of cerevisia fermentum, etc.

_Chartae Epispastica._—The cantharides should be doubled, otherwise the formula should be deleted.

_Chartae Sinapis._—Hill has stated that the direction to immerse in tepid water is not required, the heat of the body very soon setting up the fermentative action, while there is always a risk if B.P. direction be followed of destroying the ferment altogether, and rendering the mustard paper inert.

_Chrysarobinum._—The definition will now read—

"The medullary matter of the stem and branches purified by solvents."

_Cocacina._—The alkaloid should be added to the Pharmacopoeia. It is now frequently prescribed in combination with oleic acid or dissolved in soft paraffin or petroleum oil.

_Decocita._—There is no doubt that the decoctions are getting into disrepute, and that their place is being taken by fluid extracts containing the active principle in definite quantity: still it is a large order to suggest their elimination. Of course the drugs are well selected for extraction by decocion, as they contain no volatile ingredients.

_Elitizir._—The time has come when the editor of the Pharmacopoeia should recognise this class of preparations. There is a growing demand for preparations combining palatability with potency, and the ordinary syrups are objectionable from the quantity of sugar they contain.

The following elixirs are already in frequent use, and should be added to B.P.:—

_Elitizir Ossacara._—Published unofficial formulae for this are numerous, and it is for those responsible for B.P. to authorise one or produce a new one.

_Elitizir Glumidi._—B.P. formula well known and preparation largely used.

_Elitizir Phosphori._—The B.P. Formulary Committee have given a very good process, but it would entail introducing a compound tincture of phosphorus. This is not necessary if directions be given to combine the two formulae and prepare as required. Strength 1 in 50. Dose up to 2 draams diluted with water.

_Elitizir Simplex._—A vehicle to cover the taste of nauseous medicines.

_Empyema et Esenaceta._—Regarding the former, we can discuss whether something should be done to introduce the rubber basis, and, regarding the latter, whether many or all the formule should be deleted.

_Essentia Camphora, Eucalyptol and Exalgis should be made official.

_Extractum Grindelica Fluidum_ has now justified its inclusion, and the leaves and flowering tops of_ Grindelica robbata_ and_ Grindelica squarrosa_ should be made official.

_Extractum Nucis Vomicae Fluidum._ The tincture might be made from this. The solid extract, even after standardising, is apt to vary, usually becoming stronger in total alkaloids from loss by evaporation. A standardised fluid extract would always give a definite tincture. I express no decided opinion on the subject, but I think it worthy of discussion.

_Ferrum._—Under this heading I wish to bring under your notice the question of the comparative utility of permanganate of potassium and bichromate of potassium volumetric solutions as means for the determination of ferrous salts. The U.S. Pharmacopoeia has introduced the former method, and it is a question if it has any advantage over the bichromate solution. During the last few days I have made and worked the U.S. solution for the purpose. On the face of it there would appear the advantage of the termination of the reaction becoming apparent in the solution, but to neutralise this there is the very clear definition which ferricyanide of iron gives with the bichromate solution, and the fact that the latter standard solution keeps better than the permanganate. So that there are advantages and disadvantages, and perhaps it is just as well to work the solution we are accustomed to.

_Ferri Subchloridum_, better known as protochloride, should be added. It is largely used, but most unstable, and consequently requires official tests to protect it.

_Ferri Sulphas Exsiccata._—Commercial samples vary as much as to-day as they did five years ago, when I examined this salt. Perhaps 90 per cent. of FeSO4 . H2O would be obtainable instead of 97%. The U.S. Pharmacopoeia does not include it. The dose should be up to 5 grains.

_Glycerrinum Glyceri Boralis_ (Glycerin of Glycerol Borate)._—I agree with Mr. Dunlop that it would be well if all the glycerin preparations were of uniform strength, and with his remark concerning glycerrinum boratis. The preparation mentioned above and the inclusion of which I have already advocated will not conform to this standard. The U.S. formula, which is familiar to us, consists in preparing glycerryl borate by eliminating water from glycerrin and boric acid and dissolving the resulting glycerryl borate in glycerrin. It contains 50 per cent. of glycerryl borate, 31 per cent. of combined boric acid, and is more prescribed at present in my experience than any of the official glycerrins.

_Liquor Ammonii Acetatis et Liquor Ammonii Acetatis Fortior._—As you are aware, the carbonate is used for preparing the solution because the free carbonic acid which the liquid retains makes it more easily borne by the stomach. The taste and smell are better also than when prepared from hydrate. The insertion of the formula for a stronger solution minimises this advantage, for by the time it is diluted and used most of the carbonic acid is expelled. The point is, then, whether it would not be better to delete the latter altogether and return to the 1867 formula. If
a stronger solution is desired it can be made by mixing equal parts of stronger solution of ammonia and glacial acetic acid. This will be eight times the strength (over 60 per cent. ammonium acetate) of the ordinary solution.

Liquor Magnesii Carbonatis.—In one of his reports Dr. Attfield has sanctioned the reduction of the strength of this preparation, its volumetric determination (instead of gravimetric), and storage in small bottles. I have now to add to what I have already written regarding this preparation, that I agree with Symons' suggestion (it was suggested by Coull at the meeting at which I read the note) that the estimation should be made with volumetric sulphuric instead of oxalic acid. No, doubt the former acid has advantages over oxalic, more especially for expelling carbonic acid from carbonates and bicarbonates, but the oxalic solution might be retained for the hydrates and substituted for the ferrous sulphate determination of permanganate of potassium. It is held in some quarters that rather than lower the standard liquor, magnesii carbonate should be deleted, but I think the demand is increasing, and the official stamp protects the preparation.

Liquor Potassae Effervescens et Liquor Sodae Effervescens.—I shall adhere to my proposition of two years ago to introduce a minimum standard for these aerated waters. The B.P. should say that aerated potash and soda water may be prepared containing not less than 5 grains to the pint.

Liquor Strychnina Hydrochloratis.—The editor has reported that the amount of acid in the formula will be reduced according to suggestions given.

Lithii Citro-Tartrasis Effervescens.—This is one of the introductions most urgently required in our B.P. The U.S. Pharmacopoeia have adopted a formula which is in effect a lithiated saline containing 7 per cent. of carbonate of lithium and a large percentage of sugar. This would not succeed the unofficial preparations largely prescribed in this country. Usually the latter contain from 2 to 5 grains of citrate of lithium in the dram, but I am strongly of opinion that, for the sake of economy and potency, the carbonate should be used in the granules for the immediate production of the citro-tartrate. It would be an advantage to do without the sugar, more especially as the class of patients lithium salts are prescribed for find it necessary to use as little sugar as possible. Besides, the omission of the sugar increases the effervescence, and gives a briskness not to be got from a sugared granule. I show a sample made on these lines, and could offer a formula, but that is unnecessary, because the committee will produce it if they decide to include this preparation.

Lithii Salicylas.—This salt should be added. Commercial samples vary in colour and purity, and some have a strong smell of carbolic acid. We have prepared it by the following formula whiter and better than we can buy it:—Three parts of lithium carbonate, 11 of pure salicylic acid, in 25 of water, heated and evaporated at a low temperature to dryness. Then powder.

Morphine Tartras should be added as the best salt for the immediate production of hypodermic solutions.

Naphthol Beta should be included. The frequent call we have for it requires that we should have official tests for its purity.

Oleum Hydrargyri.—I agree with Mr. Dunlop that a 20 per cent. oleate would be more convenient and remain homogeneous longer.

Oleum Eucalypti.—The test for the detection of phellandrene, contained in U.S. Pharmacopoeia, should be added.

Pilocarpina Hydrochloras.—With me this is in greater use, mainly for ophthalmic purposes, than the nitrate.

Potasii Bichromas.—Now frequently prescribed in pills. Maximum dose should be stated.

Pulvis Orata Compositus, from which the mixture orata could be prepared at a moment, should be introduced. As a matter of practice this, I believe, is generally done.

Quinina Salydas, Rosarins, and Saliysyna might be added.

Tabella or Compressed Tablets.—Suggestions have been made that these should have a place in the Pharmacopoeia. I consider that care should be taken to distinguish between methods of exhibiting drugs. In the first case you exhibit in another form what is already official, in the second you introduce a substance of different chemical properties. Now there is no end to modes of exhibiting drugs, but it lies with the dispensing chemist to cultivate and improve that department. He may advise that, say, phenazonum be given in a tablet, sulphonal in a capsule, salol in a cachet, and menthol in a glycochelatin pastille. Because someone advertised either method, and a demand is made for the drug in that form, is no reason why it should become an official mode of exhibiting it. The pharmacopoeial function is to place the drugs in the hands of the dispenser, to outline processes for exhausting those that require preparation, to provide full tests for their purity, but not to multiply modes of exhibiting them.

Tinctura Benzoatis Composita.—Some time ago Dr. Stockman mentioned that he thought the aloes should be omitted from this tincture. It is mainly prescribed now for inhalation, a different purpose for which "Friar's balsam" was originally used. I think the aloes should be omitted as practically useless in an inhaler. We have prepared it without aloes, and since we introduced it, find that medical men prefer it.

Tinctura Quininas Ammoniata.—I take this opportunity to reply to the reference Professor Attfield made in his report to my formula for the preparation of this tincture with carbonate in lieu of hydrate. It is impossible to increase the quinine to 2 grains in each dram from the greater solubility of quinine carbonate as he desired. The tincture made with the carbonate by this formula—

<table>
<thead>
<tr>
<th>Sulphate of Quinine</th>
<th>150 grains</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbonate of Ammonium</td>
<td>320 grains</td>
</tr>
<tr>
<td>Proof Spirit</td>
<td>20 fl. oz.</td>
</tr>
</tbody>
</table>

is more soluble, contains the same quantity of NH₄ and quinine, but differs in having the carbinic radical in place of the hydroxyl, and it remains for a therapist to say if it is a possible substitute.
Correspondence.

POISONOUS WEED KILLERS SOLD BY SEEDSMEN.

SIR,—My attention has been drawn to the above through certain makers asking me to take up their agency, and finding that it is practically all sold in this district by the local seedsmen and florist. The order for cases is taken by the "principal or his traveller" from the country centre or their gardener, and signed by the maker of the weed killer. But is this in accord with either the Poison Act or the Arsenic Act? Where does the signing of the poison book come in? It clearly is an evasion of the law, both as regards the Poison Act and the Arsenic Act. Of course, the seed merchant or florist does not actually handle it, but, still, there is the fact of it being sent to the gardener by rail (a distance of 80 miles), and no signature given. I have a case under notice at present sent to our leading local family. I think we might with very little energy draw this portion of the trade into the net of the pharmacist.

NORTH COUNTRY CHEMIST.

WHY CHEMISTS SHOULD DISPENSE AND DOCTORS PRESCRIBE.

SIR,—Because I have seen, in my short experience, a doctor prescribe for the same patient opium and lead pills and a mixture containing tincture of muriate of iron, a dose of each alternately three times a day, and this as a last effort to save his patient’s life, any thoughtful chemist with "personal interest in his business" would point out what would happen when the lead and iron met inside his patient, and show a doctor the best way to overcome the difficulty, and the law should protect and compensate him for so doing. Then, again, doses. Another prescription which had passed through the London Stores (without comment even) was blocked by me because it contained a non-official dose of prussic acid (i.e., 10 minims three times a day), whereas upon inquiry another acid of similar name was intended. A chemist friend of mine corrected a physician who ordered in one mixture acetate of lead and acid infusion of rose. He gained his thanks.

Doubtless other chemists have seen similar cases to these. I have seen others, and believe that such are always likely to occur with any medical man who has a practice of any fair size, where time is precious and conversation of patients' friends often indulged in. The foregoing instances were by medical men outside my present district, where, I am sorry to say, doctors' dispensing is too much in vogue. Chemists want to see the horizon of the desirable change, then all would be benefited; the doctor rise with a clear head for prescribing only, take his patients one by one, put his thoughts on paper for that patient, not wait until he has run forty or fifty, and arrives home and says he can remember what each symptom was, and what each requires. The chemist would soon fall into his groove and discourage nostrum vending, and the Queen's subjects would be much safer under the new régime; and the man who now has the power to accidentally destroy life, and by giving a certificate cover up his errors, would command a higher grade for having voluntarily come out from the ranks wherein suspicion alone may mean his downfall.

Hayward's Heath.

B. O. HAYES.

THE MAJOR EXAMINATION—A SUGGESTION.

SIR,—Since the "Major qualification" and "membership of the Pharmaceutical Society" are occupying so much thought and attention of the craft, I would like, with your permission, to venture a suggestion. If I remember rightly, Mr. Cartright was deploring the fact that so few went in for the Major examination. Granted that there are those who have not the desire for the fuller development of the science of their craft, and added to those those who from a pounds, shillings, and pence standpoint view it as almost worthless, yet there are many, very many I venture to think, who have a deep longing to advance beyond the Minor, but are debared the privilege for many reasons. Finance, the forced charge of pharmacies of relatives, etc., render them unable to be away from home for even a three months' course of instruction. To meet such cases I would suggest that the subjects for the Major be taken one or more at a time, at the discretion of the candidate, and as they are passed they might be placed to his credit until he was entitled to dispute. If that were allowable, as it is in some examinations, I think a great many would at once start for the Major, and, to say the least, it would tend to the greater development of the scientific knowledge of the subjects of our profession. Since "education" and not merely the "title" is Mr. Cartwright's desire, methinks the Council might be hopefully approached and the concession made. I should be glad to hear what my brother Minor think on the subject.

M. F. C. S.

AUDI ALTERAM PARTEM.

SIR,—Having been M.P.S. ever since passing the Major, I cannot be classed with those who do not support the Society, and therefore hope you will spare a little of your space to "the other side" on the question of amending the Pharmacy Acts. Progress is all very well, and I believe in it as heartily as anyone, but it ought to be accompanied by sound common sense, prudence, and sympathy. I think that in two respects particularly the proposals of Mr. Cartwright can hardly be described as sympathetic. The lot of many a chemists is hard enough, goodness knows, and how much comfort will he be able to expect from the reflection that under the new regulations (should they pass) his wife and family in the event of his death will be deprived of support? At present there is left a hope that things may be kept going until a son be old enough to pass and take charge. We have such an instance in this city. With regard to erasing names from the Register, much objection can be taken on the same grounds. Though, doubtless, cases do arise where extreme action would seem desirable, yet we must remember that to strike a man off the Pharmaceutical Rolls takes away the daily bread, not only of himself, but also of those dependent on him. To vest such power in the hands of an irresponsible Council would be, I believe, a grave error. Witness a recent decision by the Master of the Rolls in the action of the Law Society in erasing the name of a solicitor. A word about the Preliminary. It is wonderful how opinions change when once "the gates are passed and Heaven is won." Those who are not yet through the examinations think them quite stiff enough, but once having shaken hands with the Chairman of the Board, successful men appear only a little too ready to make the Council's little finger thicker for those who follow than the loins were for them. The percentage of failures in the Preliminary is pretty high now, and one result of raising the standard might be, if not to materially increase this percentage, to diminish the entries, which would not prove the unmixed blessing some professors to think. Also of those who passed, many, finding themselves thus early qualified to register as medical students, would forsake the drudgery of pharmacy for the higher and nobler profession. Good men are said to be scarce even now, but the mediocrity of the future will be something wonderful to contemplate. If the members of our Council want to do something which will cause their names to be
"engraved with iron, pen, and lead" let them satisfy that eternal longing and bantering after a degree which possesses the bosoms of all. Let us have some handle worth more than the empty F.C.S., better to eye and ear than A.P.S. and M.P.S., and then the sons of pharmacy will arise and call them blessed, who, with Carteighe and Rymer Young, have striven to raise the level of our lives above the base pursuit of lucre.

Chester.

One of the Young Generation.

Commercial Creosote.

Sir,—Mr. Dott will, I feel sure, pardon me for adding the following notes on the recent examination of several samples of the above substance, as corroborative of his statement (Ph. J., 1864, p. 708) that "experiment does not confirm some of the statements as to its composition." The creosote of a well-known English manufacturer, on which the reputation of this substance was founded, is stated to be derived from beech wood, and is comparatively uniform in composition; the figures in the table appended, obtained by fractionation of a recently obtained specimen, agreeing closely with those found on previous occasions. It will be noted that the fraction consisting chiefly of guaiacol is very small, whilst the proportion of creosol is relatively high. The samples of continental creosote, probably derived from other sources than beechwood, used formerly to contain from 60 to 70 per cent. or more of guaiacol, and very small quantities only of creosol; but since the introduction into medicine of guaiacol and guaiacol carbonate, the percentage of guaiacol has rapidly fallen, until it is with the greatest difficulty that one obtains a continental creosote containing half that amount, as the following table indicates:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1. English</td>
<td>1'075</td>
<td>6 per cent.</td>
<td>66 per cent.</td>
<td>13 per cent.</td>
<td>21 per cent.</td>
</tr>
<tr>
<td>2. Foreign</td>
<td>1'076</td>
<td>7 per cent.</td>
<td>24 per cent.</td>
<td>18 per cent.</td>
<td>5 per cent.</td>
</tr>
<tr>
<td>3. &quot;</td>
<td>1'076</td>
<td>20 per cent.</td>
<td>15 per cent.</td>
<td>13 per cent.</td>
<td>5 per cent.</td>
</tr>
<tr>
<td>4. &quot;</td>
<td>1'077</td>
<td>13 per cent.</td>
<td>15 per cent.</td>
<td>13 per cent.</td>
<td>5 per cent.</td>
</tr>
<tr>
<td>5. &quot;</td>
<td>1'081</td>
<td>22 per cent.</td>
<td>13 per cent.</td>
<td>13 per cent.</td>
<td>5 per cent.</td>
</tr>
</tbody>
</table>

The boiling point of creosol is 219° C., whilst pure guaiacol boils at 206° C., and they may be conveniently prepared from the fractions boiling at 215°-221° C. and 200°-205° C. respectively. A striking confirmation of the suspicion that a portion of the guaiacol has been removed from the continental samples presents itself in the fact that this creosote has fallen to about half the price at which it was sold less than three years ago. It seems desirable, therefore, that a therapeutic examination of the comparative values of creosol and guaiacol should be made, and either or both of the pure substances, of definite boiling points according to results, be included in the new edition of the British Pharmacopoeia instead of the creosote of uncertain source and composition now official.

Southwark, London.

John C. Umney.

Should Doctors Dispense?

Sir,—This question has already been answered by most chemists: doctors, if they condescend to notice it at all, might answer it by another question—Should chemists prescribe? And the doctor has the best of it. He has a legal right to dispense; we chemists have not a right to prescribe, although it may be difficult to get a jury to say so. The doctor, too, if twitted upon his ignorance of drugs, may retort that, if inferior drugs are palmed off on him the fraudulent druggist, and not he, is the blame-worthy party. The sale by chemists of "patent medicines" at a microscopic profit is beside the question. Surely there can be no reason why doctors should be ready and willing to increase the chemist's income because he sells certain goods at little or no profit. My experience of doctors is that they are perfectly amenable to reason if combined with due respect and courtesy, and that they would rather help than injure the chemist who is ready and competent to serve them. But doctors know very well that it would never do to allow their patients to get their prescriptions made up "where they think proper," and prefer either to dispense those prescriptions themselves, or to send their patients to some chemist who has their confidence. When drug-stores and "cutting" druggists are things of the past, and the old historic houses are worthily represented in every chemist's shop, then and not before will doctor and chemist join hands. We shall have to wait some little time, I fear, for such a consummation.

Cambridge.

W.M.G.
As a step towards simplification, do away with Latin in the new B.P. 4th. This matter has been often referred to: With a view to maintaining what measure of simplicity has already been attained, do not introduce any new system of weights and measures. It is open to question whether it was wise to do away with the apothecaries' weights and measures, but the reason of the change —viz., to bring about uniformity with the weights and measures in common use—has a great deal to be said for it, and should not be disturbed. Do away with the 487 grs. present minims and replace it by the grain measure, designating that by its former name of minim, and restoring its old value. The fluid drachm would also go, and only the minim (=1 grain) remain of less value than the ounce (487.5 grs.) In prescribing according to B.P. measures, minims only would be used, except for fl. os. i, etc. In practice this matter of weights and measures is very much complicated by the signs used and quantities intended in physicians' prescriptions. Here they have proved themselves very conservative, for though thirty years have passed since the issue of the first B.P. and the adoption of the avoirdupois system, it is a very rare thing to see other than the old symbols used—f21 or f22—never or seldom fl. dr. i, or fl. os. i, or os. i, which are, strictly speaking, very different things. It is about thirty years, too, since it was made legal to use the metric system for purposes of trade in this country, but it has made practically no progress towards general adoption, and shows no sign of doing to. Therefore, until the physician shows some sign of giving up the old convenient forms in his prescriptions, or there is some progress towards the adoption of the metric system or even a decimal system for common use, do not make confusion worse confounded by introducing the former into the new B.P.

PHARMACEUTICAL POLITICS.

Sir,—Every chemist who has read the public utterances of the President, recently delivered, must have felt satisfied with the comprehensive policy therein set forth. I am afraid, however, that but little satisfaction can be entertained at the practical results hitherto arising therefrom in the requisite increase of new members. There cannot be two opinions about further legislation being necessary to place matters upon something like a fair basis, and thus remove the gigantic impositions chemists have at present to contend against. Even disinclined people altogether unconnected with the trade not unfrequently remark upon the present unfair and illogical state of things. We have tried what I think may be very well described as a Micawber policy during the past twenty years or so, and I believe every chemist in the kingdom will now be prepared to admit that this laissez faire policy has not been attended with even fractional success. If we are to have a healthier state of things we must wake up by determinedly adopting a policy of reform with a view of turning the existing inequalities into equalities, and, to adopt the wording of an old adage, "If we don't at first succeed we must try, try again." The President laid it down as a cardinal point that before taking action he must have not less than two-thirds of the chemists of Great Britain to back him in his legislative efforts. I think that, considering the existing conditions, there ought to be nine-tenths, when, with intelligent agitation, I feel sure that we should ultimately obtain our desires. My main object in writing this letter is to suggest that, in order to obtain the necessary complement of supporters, a circular letter should be sent to each local secretary throughout the country, urging him to arrange with his fellow-members to canvass all non-members in his district with a view of getting them to join in the campaign. I believe a personal canvass of this kind would result in a following more considerable than that the President regards as necessary. In conclusion, I would heartily endorse the opinion already expressed, that, with regard to qualification for the Council, all legally qualified chemists should be on the same footing, and that the Pharmaceutical degree should be a purely honorary one. If pharmaceutical chemists are better men, they will secure their full share of representation by virtue of their superior attainments. By adopting this course a fruitful source of dissatisfaction would be removed, and the prospects of strengthening the Society materially increased.

Ashby-de-la-Zouch.

G. W. BULLEN.

A CORRECTION.

Sir,—The value of Graville's capital paper on the determination of carbonate of ammonia in spirit of salt volatile is greatly marred by a simple error. His statement that 14.07 grains of carbonate is the B.P. complement of a fluid ounce proves that he has credited the B.P. ounce with 480 grains. This error is the more remarkable as he has avoided that of Thresh and Attfield concerning the strength of B.P. solution of barium chloride. The barium chloride test is very difficult, and I hope will be abandoned Graville's process is very promising, but requires further probation before receiving official rank. Liversewe's standard appears to me too high, the total COs contained in 5 Cc. of the spirit being only 37.56 Cc. Stockton-on-Tees.

THOS. BREATHAY.

THE BENEFICIAL FUND.

Sir,—Whilst looking through last week's issue with a friend, I noticed his name absent from the list of subscribers. I asked why he had not sent in his subscription, and he said that he had never been asked for it. It occurred to me that many of our number have put themselves in a similar position, and expect the local secretary to call for their subscriptions to this fund. If not out of place, I would here suggest that those local secretaries who do not make a call on the chemists in their districts should do so soon, whilst the subscription list is still fresh in the memory of every recipient of the Journal. I notice several towns where to my knowledge the local secretaries are active on this point and send in really good amounts, whilst many towns never send a penny, and in those places there are chemists who have big businesses and assistants earning fair salaries, all able and I hope willing to contribute if asked by some one in authority. Associate.

Answers to Correspondents.

W. H. Burrell.—Iodine with potassium iodide and hydrochloric acid will give a crimson copper nitrate a green and potassium chromate a yellow. Dissolve in water until satisfactory tints are obtained, filter and, after standing for some time to deposit, decant off clear solutions. Write again if you require further information. A. R.—It is made in the United States. Probably Messrs. Munn and Co., 561, Broadway, New York, could give the information you ask for.

Jas. Robb.—There is no immediate intention of publishing a general index to the Journal, as there does not appear to be sufficient demand for it to justify the expense.

Communications received from Messrs. Austin, Bul- len, Campbell, Church, Cope, Hayes, Hacking, Hii, Knoll, Lelles, Nightingale, Ransom, Robb, Smith, Umney, Whinney, Whittaker, Wood, Wright, Young.
THE CHEMICAL HISTORY OF ACONITINE
A REPLY TO MR. W. R. DUNSTAN.

BY MARTIN FREUND.

Last year I published, in conjunction with P. Beck, an investigation of aconitine, a preliminary communication, which contained the results of our work, appearing first,† and subsequently a more extended memoir, with the experimental data.‡ In the latter appeared,§ there was also a notice by Mr. Dunstan, which I have hitherto left unanswered because it was there stated to be the intention of the writer to discuss the formulae we had given, and I anticipated having then an opportunity of replying to the false statements contained in that notice. But as a year has now elapsed without Mr. Dunstan having carried out his declared intention, it is not therefore necessary that I should defer any longer a correct statement of the facts.

In the preliminary communication above mentioned, Beck and I stated that the formula 
\[ \text{C}_{11} \text{H}_{18} \text{O}_{13} \] 
assigned to aconitine by Wright, and modified by Dunstan, was incorrect, and that it should be replaced by 
\[ \text{C}_{12} \text{H}_{16} \text{O}_{14} \].

"While the hydrolytic splitting of aconitine was represented by Wright—and also by Dunstan—by the equation
\[ \text{C}_{12} \text{H}_{16} \text{O}_{14} \] 
\[ \text{H}_2 \text{O} \] 
\[ \text{C}_{11} \text{H}_{18} \text{O}_{13} \] 
we showed, on the contrary, that this alteration takes place in two phases—
I. 
\[ \text{C}_{11} \text{H}_{18} \text{O}_{13} \] 
\[ \text{H}_2 \text{O} \] 
\[ \text{C}_{12} \text{H}_{16} \text{O}_{14} \] 
II. 
\[ \text{C}_{11} \text{H}_{18} \text{O}_{13} \] 
\[ \text{H}_2 \text{O} \] 
\[ \text{C}_{12} \text{H}_{16} \text{O}_{14} \] 

We further produced evidence that the product 
\[ \text{C}_{12} \text{H}_{16} \text{O}_{14} \] 
resulting according to equation I., was identical with the "isaconitine" of Dunstan, to which he had assigned the formula 
\[ \text{C}_{12} \text{H}_{16} \text{O}_{13} \] 
as being an isomer of aconitine.

We also showed that the product 
\[ \text{C}_{11} \text{H}_{18} \text{O}_{13} \] 
resulting according to equation II., was identical with aconine, for which Dunstan had confirmed the formula 
\[ \text{C}_{12} \text{H}_{16} \text{O}_{14} \] 
assigned to it by Wright.

Lastly, we deduced from our observations the ultimate conclusion that aconitine is to be regarded as acetyl-benzoyl-aconine—
\[ \text{C}_{12} \text{H}_{16} \text{O}_{14} \] 
\[ \text{COCH}_3 \] 
\[ \text{CO}_2 \text{H} \]

Although in the above-mentioned notice by Mr. Dunstan he deferred to "a future occasion" the discussion of our formulæ which differed so much from his own, he hastened to make a claim of priority in regard to the results which had been communicated by us.

I do not consider the result of our investigation of sufficient importance in itself to be worth entering into a dispute as to priority. But the statements of Mr. Dunstan are so contrary to the facts of the case that I cannot allow them to pass without contradiction.

Mr. Dunstan asserts that the observation that aconitine splits up first into acetic acid and isaconitine had already been published by him on January 21st, in the Proceedings of the Chemical Society. In contradiction of that statement I affirm that in those "Proceedings"—which, so far as I am aware, contain abstracts prepared by the authors of the papers read—isaconitine is throughout treated as the isomer of aconitine, and not as a product of its splitting.

Mr. Dunstan has published in the same number of the "Proceedings," the observation that aconitine heated dry to 190° C., loses one molecule of acetic acid.‡ In the notice published in the Berichte he says: "The obvious conclusion that aconitine must be acetyl-benzoyl-aconine, and the so-called "isaconitine" benzoyl-aconine, though not stated in so many words in the abstracts, is given in the original papers which appear in the number of the Journal of the Chemical Society now being published."

In the first place, I have to mention that the production of acetic acid in the hydrolysis of aconitine had already been demonstrated in 1892 by Ehrenburg and Pflüger.‡ I affirm, moreover, that there is not in the "Proceedings" one single word to indicate the above-mentioned "obvious conclusion." Only in one place is it mentioned that the authors (Dunstan and Carr) are at present engaged in investigating "whether aconitine may not be an acetyl derivative which loses its acetyl group on hydrolysis," and then there is in the "Proceedings" this further statement: "If the latter view should prove to be correct, the nomenclature and formulæ of aconitine derivatives will need entire revision."

I come now to the contents of the "original papers" which were published in the March number of the Journal of the Chemical Society, while the previously mentioned number of the "Proceedings" was issued on January 27, and our paper (sent in on February 8) was published in the Berichte on February 19.

In these "original papers" the point which is referred to in the abstracts as having to be ascertained, has all at once become a demonstrated fact. The nomenclature and the formulæ of aconitine derivatives are altered—aconitine is represented as acetyl-benzoyl-aconine, and isaconitine as benzoyl-aconine. Mr. Dunstan speaks, however, to have overlooked the fact that in the first of the three papers in the same number—isaconitine is expressly represented to be an isomer of aconitine, and on that account it is proposed that the name "picaconitine" should be abandoned. In favour of his very suddenly acquired new views, Dunstan was compelled to throw overboard the formulæ he had employed for several years. Since the old isaconitine formulæ, 
\[ \text{C}_{12} \text{H}_{16} \text{O}_{14} \] 
requires almost the same values as the newly adopted one, 
\[ \text{C}_{12} \text{H}_{16} \text{O}_{14} \] 
Mr. Dunstan resolved upon making that alteration on the basis of a single

† Ibid., 67.
gold determination although it was not in accord with a whole series of analyses of the gold salt, which agreed well with the old formula.

Calculated for the old formula, ..... 21.46 per cent.

" Dew." ..... 22.50

" Found." ..... 22.18

No new analytical data at all were given for acouine, but the old formula, C₇₀H₈₀NO₂₃, was altered without further consideration to C₇₀H₈₂NO₂₄.

It is upon such a publication that Mr. Dunstan bases his formulæ and his claim to priority! Between his formulæ and those we have proposed to adopt there are, however, such differences in the corresponding amounts of carbon that a decision between them is very easy to make. Since, however, Mr. Dunstan has not entered upon the discussion he intended, his silence must be accepted as an acknowledgment of the accuracy of our formulæ.

For the rest, after having waited for a whole year for a reply from Mr. Dunstan, I shall no longer hesitate to seek for additional evidence in support of our formulæ by a further investigation of acouine and its derivatives.

THE APPROACHING REVISION OF THE BRITISH PHARMACOPOEA.
FROM THE POINT OF VIEW OF A PHARMACIST
BY W. A. H. NAYLOR.

The views expressed by Dr. Lauder Brunton under the heading of "The Approaching Revision of the British Pharmacopeia" are emphatically those of a prescriber, and are entitled to the respect of all thoughtful pharmacists. It is impossible to rise from the perusal of the article without the conviction that this gentleman desires not so much to extend by explanatory sentences the information already supplied by the Pharmacopeia as to alter its character. The result of the change he proposes would be to make it a combination of "The Elements of Pharmacy" with suggestive hints on the "Art of Dispensing and Prescribing." His recommendation that the volume should be informative up to a certain point on those subjects is based upon his statement that the Pharmacopeia is primarily intended for the medical man, and that this individual may be assumed not to possess an elementary knowledge of the properties of the drugs he prescribes. Hence he contends that the Pharmacopeia ought to instruct him that ether will burn and that its vapor is inflammable, and therefore should not be brought in proximity to a fire. The same precaution is to be repeated under the heading collodion. Truly this is a revelation of ignorance on the part of the medical fraternity, which will come to the pharmacist in the light of a surprise. But this eminent pharmacologist goes a step further, and asks that the approaching revision shall give the result of chemical changes which may be brought about by the admixture of two or more ingredients which a medical practitioner may have it in his mind to prescribe. Thus the character and tests of perchloride of iron should include an instruction to the effect that when brought into contact with iodide of potassium free iodine is liberated. In like manner that borax when dissolved in glycerin sets free boric acid. In short, Dr. Brunton's demand appears to be for a prescriber's manual rather than a pharmacopeia. The want of knowledge of pharmacy which he assumes his brethren to possess may be gained by a careful study of one of the admirable text-books devoted to the exposition of the principles of this branch of medicine, whilst acquaintance with chemical reactions can be appropriately made through the agency of an elementary text-book of chemistry. As to the form, in respect of elegance and palatability, in which a remedy should be administered, is it too much to suggest that the trained pharmacist might, with advantage to the patient and credit to the prescriber, be more freely consulted? The suggestion that the Pharmacopoeia should follow the lines of Squier's 'Companion' or the 'Extra Pharmacopoeia' is not one that could efficiently be carried out, in view of the long intervals that elapse between the issue of successive editions. The same objection applies to the act of regarding the volume in the light of a student's treatise on pharmacy. An educational work is mainly valuable to the extent that it reflects present-day knowledge. The intention of the Pharmacopeia is to supply standards to which the remedies named therein shall be referable in respect of their nature and composition, thereby ensuring uniformity. The question arises, can the scope of the original intention, as expressed by the Medical Council in the present British Pharmacopeia, be usefully enlarged? The proposed introduction of the imperial element, which has met with widespread approval so far, gives an answer in the affirmative. Should not a pharmacopeia be confined to giving authoritative directions for the making of standard medicines, and to supplying characters and tests for indicating the genuineness and quality of the drugs, and the composition and purity of the chemicals therein referred to? On what lines may we work in the hope of effecting improvement in the projected Imperial Pharmacopoeia? Are they not briefly these:—

(a) Improved methods and formulas for the production of some of the Galenics—notably tinctures and ointments.

(b) An extension of the tests, with more precise directions as to their mode of application.

(c) The omission altogether of the class known as cataplasms.

(d) The omission of detailed directions for making definite chemicals which are known to be produced only on the manufacturing scale, and the purity of which can be ascertained by the application of suitable tests.

(e) To meet the convenience of prescribers by admitting of easy calculation, the potent remedies represented by liquor arsenici hydrochlor., strychninae and sodii arseniat., should have a strength of x grains in 100 minims.

(f) A possible increase in the number of liquid extracts and injections, employing for the latter a preservative suitable in each case.

(g) An avoidance of too free a use of synonyms.

(h) The inclination to multiply standardised preparations, to be yielded only when it is known that the preparation is capable of producing the therapeutic effect desired.

(i) The adoption of the metric system of weights and measures, and the introduction of a table of solubilities.
I am satisfied that the gentlemen elected by the Council of the Pharmaceutical Society, at the instance of the Medical Council, to assist in the revision of the Pharmacopoeia will bring to the prosecution of their task zeal, knowledge, and honest work, qualities the patient exercise of which in the daily practice of their craft has deservedly elevated them to a foremost position in the domain of British pharmacy.

**NEW LABORATORY DEVICES.**

**MODIFIED KNORR’S EXTRACTION APPARATUS.**—This modification of Knorr’s apparatus is suggested by Oma Carr (Journ. Am. Chem. Soc., xvi., 868) to obviate several inconveniences associated with the ordinary form. To the inverted percolator-dome c, is adapted a tube, a b, of convenient size, the shoulder of which is supported by the small triangle d d, arranged upon the rounded top of the flask neck. The flask, of 100 C.C. capacity and without a rim at the mouth, should project above the cork f, about two inches.

To bring extract-solutions to definite volume, the apparatus should be sunk in a water-bath to a sufficient depth to prevent the solvent accumulating upon the cork. It is readily adapted to the condenser of the Knorr extractor, as shown at 1, and upon completion of the extraction the cork f is easily removed, and the flask wiped and dried without danger or annoyance being caused by mercury globules.

**NEW WASH BOTTLE.**—The wash bottle shown in the illustration represents the form that G. C. James (Scient. Amer., lxxii., 5) has found convenient for hot water, etc. One figure represents the bottle complete; the other shows it in use, and also shows a large scale view of the valve. Its construction is obvious. The wire crosses a piece of rubber tubing. When the wire is depressed it squeezes the tubing against the wooden block on which it is mounted and thus closes it valve-fashion. The middle finger controls the wire of the valve, allowing the free use of the first finger to direct the stream—a great improvement on other similar apparatus. When the bottle is reversed, the middle finger also controls the stream issuing from the mouth tube—a very convenient feature. After a short use of the bottle, one soon becomes accustomed to the mechanism, so that the mouth and hand work together. The air chamber ordinarily above the water is sufficient to eject the water for five or ten minutes, and with the hot water bottle it is only necessary to shake the water, and the steam liberated is ample to force the water from the top. Another great advantage is that one runs no risk of burning the mouth, as the valve prevents the steam returning until the mouth is removed.

**THE APPROACHING REVISION OF THE BRITISH PHARMACOPEIA.**

**PHARMACEUTICAL DEFECTS IN THE PRESENT BRITISH PHARMACOPEIA FROM THE MEDICAL POINT OF VIEW.**

BY WILLIAM WHITLA, M.D.,
Professor of Materia Medica and Therapeutics in the Queen’s College, Belfast; Physician to and Lecturer on Medicine in the Belfast Royal Hospital.

The announcement that the General Medical Council have commenced operations for a revision of the national Pharmacopoeia has been received with no small amount of interest by the medical profession. This interest has not diminished since the publication of the debate upon the presentation of the report of the Pharmacopoeia Committee to the Council, which doubtless has had the effect of directing the attention of the profession more closely than usual to the methods by which the revision is proposed to be carried out. The General Medical Council, and especially the able and untiring Chairman of the Pharmacopoeia Committee, have earned the gratitude of every medical practitioner at home and in the Colonies for their labours in former revisions.

It is, therefore, in no spirit of fault-finding or censoriousness that it is proposed to examine the methods by which the revision in former years has been carried out. We must look at the inherent difficulties of the work with the view of finding out if possible how they may be overcome or minimised, and, if possible, how a higher standard of excellence may be reached in the next issue of the Pharmacopoeia. The work must always be regarded from two very distinct standpoints—namely, from the point of view of the pharmaceutical chemist and that of the practitioner of medicine. The Pharmacopoeia is designed as a guide or aid to the pharmacist who dispenses, as well as to the physician who prescribes the remedies for disease. The General Medical Council have always broadly acknowledged this, and, in addition to engaging a number of pharmaceutical experts to assist in the work, they return thanks in the preface to the last

* From the British Medical Journal.
pulp, we come to the group of cataplasmas, the retention of which is a serious blemish upon our national Pharmacopoeia. The formula of almost every member of the group may be safely pronounced to be at variance with present therapeutic knowledge and experience. One of the most obvious blunders is the directions for preparation of the cataplasms of hemlock, namely, the instruction to evaporate the hemlock juice to half its volume. The result of this is to completely destroy the property of the drug, unless indeed the evaporation be carried out at a low temperature, which is not stated. Moreover, as it is impossible for the chemist to make and supply these poultices, it is difficult to see why they have been retained. It is probable that few physicians, when ordering a mustard poultice, intend that the official mustard cataplasm, which consists of an equal quantity of linseed meal and mustard, should be supplied, nor is the official mustard paper recognised by physicians as a success.

There was a time when something might have been said for the retention of the sulphates of cinchonine and cinchonidine, but from a therapeutic point of view the two pages devoted to their characters and tests are at the present day worse than lost space.

The confections may be regarded as belonging to a past time, and as veterans they lie superfluous on the stage; those of scammony, hips, opium, and, perhaps, turpentine are seldom used. Much may be said for the retention of confections of sulphur, pepper, and senna, but when one considers that the latter preparation contains nine substances, four of which (that is, figs, tamarinds, cassia pulp, and prunes) are solely retained for its preparation, it is obvious that the confection of senna is retained at serious cost, especially as the pharmaceutical process directs the rejection "of the seeds and other hard parts" upon which the laxative properties of its ingredients to a considerable extent depend. If the directions for evaporating the confection at the end of the process be followed the active principle of the senna is very considerably destroyed, and this official representative of polypharmacy is rendered almost useless, as is also the case with the syrup of senna.

The decoctions and plasters afford numerous examples of inert preparations, but perhaps the small group of enemata afford the best examples of official preparations framed in opposition to the recognised principles of physiology and therapeutics. Thus, the enema of aloes is made to measure 10 ounces, and that of sulphate of magnesia 16 ounces, quantities which obviously cannot be retained for any time in the body. It is clear that these five preparations should be excluded, as the physician can give directions when he wishes to use enemata of assafoetida and opium, the only members of the group of any utility.

The space of the present article does not permit of a review of the numerous extracts, many of which are seldom employed, and some of which—notably conium and dandelion—are inert when the official formula is followed. It has been demonstrated that the hemlock extract may safely be swallowed in enormous doses, its active principle having been destroyed by the high temperature of the
evaporation. Perhaps no more obvious example of the
defect of a pharmaceutical preparation could be men-
tioned than that of glycerin of borax. Formerly this
valuable preparation, which was faintly opalescent,
consisted of 1 ounce of borax dissolved in 4 ounces of
glycerin, but in the last revision 2 ounces of water
were added, the result being a thin bright liquid, which
does not adhere to the diseased mucous membrane,
but immediately flows off, and is practically valueless
as a therapeutic agent. By using the borax in crystals
a clear, bright and adhesive liquid would have
resulted. The utility of the preparation was sacrificed
to elegance in pharmacy, whilst a little more pharma-
cutical knowledge would have redeemed it.

The entire group of infusions should be revised, and
most, if not all, must be omitted from a medical point
of view. Their strength and actions vary so much and
they are so liable to spontaneous changes, even when
combined in mixture form with other drugs, that the
days of this form of Galenical preparation are already
numbered, and, as Professor Leech has shown, they
have practically disappeared from the other phar-
macopoeias of the world.

Another group of preparations which shows serious
defects is the mucilages, though some of these could
be easily remedied. Thus mucilage of scopolia, which
soon becomes acid when kept in ordinary vessels, might
retain all its properties fresh if the Pharmacopœia
supplied the directions for enclosing it in small sealed
phials completely filled and excluded from the air and
light. It is a common occurrence to see mischief
causcd in the treatment of stomach affections by this
acid mucilage, especially as it is so often used to sus-
pend bismuth. For similar reasons the hypodermic
injections are actually dangerous; ergot decomposes,
and when injected abscesses result, a state of matters
which could be easily avoided; indeed, much can be
said for excluding all preparations liable to speedy
spontaneous decomposition. The injection of mor-
phine requires serious attention. It is quite too
powerful; every minims contains one-tenth of a grain,
and no matter how careful the physician may be, he is
liable to inject one or two minims more than he in-
tends. Owing to its strength the writer regards it as
a positively dangerous preparation, and it is probable
that death has resulted from its use in the hands of
young physicians not accustomed to the daily use of
the hypodermic syringe. The introduction of disc or
tablets containing alkaloids in soluble form should
replace these unstable injections.

The practically inert aromatic mixture of iron
known as Heberden's ink and the vinum ferri are still
left as blemishes; they are valuable chalybesites no
doubt, but only in the absence of the host of reliable
preparations of iron. The same remarks will apply to
the pill of iodide of iron.

The saccharated carbonate of iron may be instanced
as an example of a reform urgently required in the
official pill masses; "this carbonate (if reckoned as
anhydrous) forms about one-third of the preparation,"
but commercial specimens, prepared by the official
process, generally are found to yield about 20 per cent,
of real ferrous carbonate. The dose of the prepara-
tion is given as 30 grains, which would mean, when
mixed with the official excipient, about one dozen fa-
sired pills.

Extractum rhamni frangulae (never used as an
exciptent) has its dose fixed at 15 to 60 grs.
This means that when made into firm pills of fair size the number required to be adminis-
tered will amount to at least from 4 or 5 to 15 or 18.
The dose of many other extracts introduced into the
Pharmacopœia for administration as pills is so large
and bulky as to render them useless; this becomes
even more evident when one remembers that the pro-
longed evaporation deteriorates their active principles.

Of the 51 liquors, 18 syrups, 18 spirits, and 75
tinctures, much might be said from a purely pharma-
cutical point of view, which is outside the scope of
the present article. That only a very small percentage
of these 182 preparations are in use amongst practi-
tioners cannot be denied, and the reason is obvious—
their strengths and doses are so various that it is
found impossible to remember either, and after
the ordeal of the examination in materia medica
it is got over the young physician breaks acquaintance
with the great majority of his official friends, and too
often drifts into the daily use of semi-proprietary or
ready-made pharmaceutical compounds, or else settles
down to the routine use of a very limited selection of
British Pharmacopœia drugs and their preparations.

The lozenges are a very doubtful addition to the
Pharmacopœia, and the recent perfection of the manu-
facture of tabloids should suggest the advisability of
excluding these remnants of the old-world pharmacy
altogether. If administered for their local action
upon the mucous membrane of the mouth and fauces
the sugar, mucilage, and gum seriously interfere with
the action of some of them. If this group of prepara-
tions is to be retained a plea must be made for a
lozenge containing carbo!ic acid, such a lozenge
would be worth more than the present list of
twelve.

There are no fewer than forty-five unguents in the
present Pharmacopœia, and upon these a separate
article might be written with advantage: from the
medical standpoint the chief objection is the lamen-
table want of anything approaching uniformity of
strength. Thus the list of forty-five unguents will be
found to contain preparations of no fewer than twenty-
eight different strengths. In objecting to the want of
uniformity in the strength of tinctures and Galenical
preparations to be swallowed it always can be
answered that the dose is an item to be considered,
but in dealing with ointments, many of which are
inert, there is certainly less to be said against uni-
formity of strength. It is rather surprising to learn
that out of a total of forty-five of these preparations,
there are twenty-eight of which no two are of the
same strength. The result of such an arrangement is
that the physician learns practically to ignore the
official list, and, when he requires an
unguent, writes a recipe for a preparation of his
own, as it is almost an impossibility to remember
the strength of even a fair percentage of these pre-
parations. An even more serious objection to the
group is the unfortunate selection of a basis consisting of a mixture of hard and soft paraffin in several of them. If anything can be said for such a basis from a pharmaceutical point of view, experience proves that it is objectionable from a medical point of view, and in some ointments it destroys their usefulness. As a rule, the official directions for the making of ointments are very defective; in no place is it made clear that the powdered substance is to be rubbed laboriously and patiently with a very small quantity of the basis before the remainder is added; there is no class of preparation requiring so much care and skill, and such curt directions as “mix thoroughly” are insufficient.

The vapours of the British Pharmacopoeia are seldom employed and so out of touch with modern therapeutic notions that, like the cataplasmata, they are so certain to be excluded in the approaching revision, that nothing need be said of them. The wines should probably also be excluded, for if sherry or other wine be found in any particular case to be a better menstruum than weak spirits, it may be used, and the resulting preparation called by its proper name—a tincture. The vinum ferri should certainly be excluded; the quantity of iron contained in it is most variable, but never enough to be of any therapeutical value when given in the official dose of 1 to 4 drachmas.

The above-mentioned objections are given not as a complete list of the pharmaceutical defects in our national Pharmacopoeia, but as a sample of what must be remedied if the new work is to become one of which we shall not be ashamed. They go to prove conclusively that the valuable suggestion of Dr. Lauder Brunton should be acted upon—that “skilled labour and much experimental work, necessitating the expenditure of a good deal of time and money,” should be provided by the General Medical Council.

If this is obviously necessary for the judicious weeding out of the grave defects and worthless drugs and preparations in the present British Pharmacopoeia, how much more obviously necessary is it for the introduction of new remedies and new Galenical preparations—a subject not within the scope of the present article.

We trust that the compiler of the work will not be misled by the valuable suggestions of Dr. Brunton.

The first by whom the new are tried, but the profession in all English-speaking countries will doubtless also hope that they will not

Be yet the last to lay the old aside.

An analysis of the inconsistencies and lack of uniformity evident all through the 1885 issue proves that these arise from the patchwork nature of the original issue in 1867, when the compilers had to reconcile the various interests represented in the old Edinburgh, London, and Dublin pharmacopoeias. This Herculean task was accomplished with great ability, but the time has now come when the work must be undertaken in a totally different spirit, and the revisers must go to the root of the matter and produce a volume which will be an index of the advanced pharmacy and therapeutics of the day. The great and only danger appears to be that of haste; it will take at least a few years before this result can be accomplished.

NOTES ON RECENT SCIENTIFIC INVESTIGATION.

FORMATION OF SECRETIONS IN PLANTS.—Dr. A. Tschirsch announces the remarkable discovery that in all normal cases which he has been able to examine the formation of a secretion it is a function, not of the protoplasm, but of the cell-wall. In schizogenous passages the secreting cells which clothe the canal contain a resinosogenous layer, which is often vacuolar; in schizo-lyigenous cavities the secretion is formed in peculiar caps of cell-wall belonging to the cells which enclose the space. In the oil glands of the Labrador, Composite, etc., it is produced entirely in a subcortical layer of the cell-wall, and this is the case also with the papillae which project into the intercellular spaces of the rhizome and base of the leaves in Asparagus filica-mas, and in many, if not all, extra-floral nectaries, the secretion lifting the cuticle off from the palisade-like secreting tissue. In all stigmas examined by the author, the secretion is formed in the subcortical mucilaginous layer of the papillae, into which the pollen tube makes its way. Similar observations were made on the oil of oil glands, and on the resin which is formed in the duramen of trunks. But, although the secretions are formed in the cell-wall, they are never produced by metamerorphism of the substance of the cellulse itself. Dr. Tschirsch ascribes to all resins a uniformity in chemical composition, regarding them as compounds of aromatic acids with a peculiar group of alcohols which he calls resinaols. (Botanisches Centralblatt, Vol. IX, 1894, pp. 289-298.)

Herr A. Béchteres has studied the mode of formation of the secretion in schizogenous receptacles, especially in the elongated cavities of the Abietinaceae, Composite, Umbelliferae, Burseraceae, and Coniferae. He finds the secretion to be present in these receptacles from the earliest stages of their formation, while none is contained in the cells of the surrounding tissue. Resin could never be detected outside the resin passages. A group of cells, early distinguished by their colourless contents, arising from the mother-cell of the canal, forms a coating of mucilage where these cells adjoin the epidermis, and this mucilage contains the resinosogenous substances. The extent to which the canal is ultimately filled with resin varies greatly. A membranous structure, the inner pellicle, is formed at the point of contact of the resin with the layer from which it springs, and often contains granules of various kinds. (Mitteil. Naturf. Gesell. Born, 1894, pp. 74-109.)

According to M. G. Bonnier, the production of honey or nectar in plants is greatly influenced by the nature of the soil. Thus the white mustard produces a much larger quantity on a calcareous than on an argillaceous soil; the buckwheat more on a siliceous than on a calcareous soil. An argillaceous soil is favourable to the production of honey in Phacelia tanacetifolia, a calcareous soil to its formation in Iasis tintoriera and Medicago sativa. The saffron is nearly indifferent to the nature of the soil (C. R. de l’Assoc. Francaise pour l’Avancement des Sciences, 1894, pp. 567-569).

FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, MARCH 9, 1895.

Editorial Department.

Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

Advertisement Department.

Advertisements and remittances must be sent to "Street Brothers," 5, Serle Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased, and to whom Cheques and money orders should be made payable.

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary—Mr. Richard Bremridge, 17, Bloomsbury Square, London, W.C.

THE COUNCIL MEETING.

At the meeting of the Council on Wednesday, one-third of the members were absent through indisposition or for other reasons. After the usual preliminary business, a letter was read, in which Mrs. Burroughs acknowledged that in which the Council had expressed its sympathy on the death of Mr. S. M. Burroughs. This was followed by elections—6 members, 23 associates, and 42 students—after which the report of the Finance Committee was considered. The chief items of expenditure were in connection with the new buildings at Edinburgh, and it was stated that certain extras involved an addition to the original estimate for these of between £400 and £500. Altogether, some £2500 had been expended on capital account, and £600 on apparatus and materials. On the Benevolent Fund account, a donation of £50 had been received from Major Probyn, one of ten guineas from Mr. J. G. Richards, Hastings, and one of five guineas from Mr. Trickey, Eastbourne.

There was nothing of special importance in the Benevolent Fund Committee's report, and the only items of interest in that of the Library and House Committee referred to the insurance of the Society's premises in Scotland, and a grant to the Sheffield Pharmaceutical and Chemical Society for educational purposes. The amount of the latter had been fixed, after careful consideration, at £25 rather than £50, in the hope that local contributions might be forthcoming to a similar amount. The preparation of the annual report was referred by the Council to the Library and House Committee, as usual, and it was resolved to hold the annual meeting on Wednesday, May 22 next. A letter had been received from Mr. Chas. Umney, suggesting that application should be made for permission to give evidence from a pharmaceutical point of view before the Select Committee of the House of Commons, which would deal with the Weights and Measures Act Amendment Bill, introduced by the London Chamber of Commerce (ante p. 588). A resolution appointing the President and Mr. Martin to give evidence on behalf of the Council, on permission being obtained, was passed accordingly. The death was announced of two corresponding members of the Society: Mr. Andrew Ferrin, Chemist to the Government Medical Council, Moscow, and M. Jean Edouard Bonner, Curator of the Botanical Gardens, Brussels. The President pointed out that both were distinguished in their respective lines of work, and said it was only right that their loss should be recorded on the minutes. Mr. Wm. Gregory was appointed local Secretary for Weymouth, and authority was given the Registrar to make proof of debts owing to the Society, after which the report of the Law and Parliamentary Committee was read.

This report contained a recommendation that no Bill be introduced in Parliament at present, and the President said that the Committee felt it was hopeless to move during the current session of Parliament, owing to the congestion of public business. At the same time there was no desire to forget their obligations to the many active associates in business who were doing such excellent work throughout the country. Mr. Harrison regretted the decision that had been come to, and strongly objected to an indefinite postponement of the matter. It would not be right to defer consideration of it until the eve of another session, and he thought an early opportunity should be taken of formulating a scheme embodying what was generally demanded. This might then be considered by the members before the autumn meetings, and a healthy public opinion be formed with regard to it, besides which a certain measure of enthusiasm might be usefully called forth. The Committee ought to meet again at an early date to formulate a scheme, or the same difficulty would occur again. It was his intention to press the consideration of the curriculum, consolidation of the Society, and company trading. Mr. Martin agreed with the opinions expressed by Mr. Harrison, but Mr. Atkins thought the Committee had acted very prudently. After some further criticisms by Mr. Southall, however, the action of the Committee was agreed to.

THE PHARMACOPOEIA AS A THERAPEUTIC GUIDE.

The Apotheker Zeitung, in referring to the contemplated revision of the British Pharmacopoeia, mentions the suggestion, made at the last meeting of the General Medical Council, to introduce information of a therapeutic nature as an assistance in the administration of medicinal agents and in prescribing. This suggestion is considered by our contemporary to be totally opposed to the proper character of a pharmacopoeia.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS. [March 9, 1895

APPENDIX TO THE GERMAN ARZNEIBUCH.

The supplement to the 'Codex Medicamentsarius' has been closely followed by an appendix to the 'Arzneibuch für das Deutsche Reich,' or third edition of the 'Pharmacopoeia Germanica.' But whereas a period of eleven years has elapsed between the publication of the original French work and its additions, the German medicine book was only published on June 17, 1890, so that five years have not passed before it has been found necessary to bring it somewhat up to date. The additions and alterations are contained in thirty-two pages, less than one-third the space occupied by the extension of the Codex, and they are generally of a very different character to those that have found favour in the neighbouring republic.

Of the fifteen novelties the first is camphoric acid in colourless crystals or white powder (m. p. 178°-180°), and this is followed by hydrobromic acid (a. g. 1.908). Aqua cresolica consists of one part of cresol soap solution to nine parts of water, and contains five per cent. of crude cresol. Bismuth subsalicylate is added. Then follow cerocili (wand-stäbchen), a sort of flexible medicated bougie. These were originally made of linen dipped in melted wax and rolled. Anthrophores are similar, but contain a spiral spring. Caffeine sodio-benzoate is described as a white amorphous powder (maximum dose, 1 Gm., not to exceed 3 Gm., daily). Other additions are crude cresol; 35 per cent. solution of formic aldehyde (a. g. 1.079-1.081); cresol soap solution (crude cresol, 1, potash soap, 1); lithium salicylate; corrosive sublimate pastilles (1 or 2 Gm. each, composed of equal parts of mercuric and sodium chlorides, coloured with aniline red); cresocote pills (cresocote, 10, liquorice powder, 12, glycerin, 1); thiorubrine sodio-saliclylate (diuretin, maximum dose 1 Gm., not to exceed 8 Gm., daily); tincture of aloes (aloes, 1, strong spirit, 5); cantharides ointment for veterinary purposes (cantharides, 2, olive oil, 4, yellow wax, 1, turpentine, 2, sulphur, 1); and a new reagent—rosolic acid (1 per cent.).

The alterations are more numerous than the additions: they consist chiefly in the addition of new tests, modification of doses, etc. They affect purified wood vinegar (5 per cent. acetic acid); benzoic, carboilic (liq.), citric, and tannic acids; lard; ethyl bromide; bitter almond water (a. g. raised to 0.970-0.980); balsam copaiba (ammonia test introduced); frangula bark (not to be used until a year after it is purchased—nach dem Einkaufe); fluid extracts of condurango, frangula, and hydrastis; citrate, saccharated carbonate, saccharated oxide, sulphate, and dried sulphate of iron; ferrum pulvératum and reductum; glycerin; hyoscine hydrobromide (renamed scopoline hydrobromide); iodine (dose reduced to 0.02 Gm., daily maximum 0.1 Gm.); solution of acetate, now subacetate, of iron; solution of arsenic with potassium carbonate (Fowler's solution, uncoloured); aloes and iron pills; suet; sulphonal (dose reduced to half, now 2 Gm., and not to exceed 4 Gm. daily); wine, and pepsin wine (time of maceration reduced from eight days to twenty-four hours).

THE BRITISH PHARMACOPEIA.

It is satisfactory to find that at last a useful paper has appeared in the series on the revision of the Pharmacopoeia, published in the British Medical Journal. Dr. WHITLA, whose paper is reprinted in the present issue of this Journal (see p. 775), approaches the subject in a manner which proves his familiarity with it, and his knowledge of actual needs. He also appears to have grasped the distinction between the relation of pharmacists and medical practitioners, respectively, to the Pharmacopoeia, and it is interesting to note that it is in his opinion that only by having a medical editor to collaborate with a pharmaceutical editor "can a pharmacopoeia be brought out which will index the medical mind of the nation or be creditable to British medicine," as well as a representation of the advanced pharmacy and therapeutics of the day. An excellent paper on the revision of the B. P. from the pharmaceutical point of view, by Mr. W. A. H. NAYLOR, will be found at p. 774. It may be stated that this was in type before certain of the suggestions contained in it were, in a measure, anticipated by other correspondents.

LEAD IN WATER.

At a meeting of the Yorkshire Branch of the Incorporated Society of Medical Officers of Health, on February 14, a discussion on the presence of lead in potable waters was introduced by a paper read by Dr. KAYS of Huddersfield, who argued that all soft water should be regarded with suspicion. He thought the action of water on lead was a complex one, though the presence of acid was probably one cause of such action. Dr. GARRETT of Cheltenham, credited free oxygen with the effect produced on lead pipes, and recommended calcium carbonate in preference to the sodium salt as a preventive. Dr. JOHN BROWN of Bexop, was of opinion that alkalies, except in the form of carbonate, would not prevent solution of lead, and suggested that the stocking of reservoirs with fish was beneficial. Dr. SCAFFERT, of Keighley, was convinced that peaty matter was a manufacturer of acidity, and that unless the acid thus formed was neutralised, the water containing it was bound to set upon lead. Dr. WHITELOGE, Medical Officer of Health to the West Riding County Council, preferred soda to lime as an antacid, but thought lead service pipes should be prohibited in the future. Finally a resolution was adopted to the effect "that, as regards moorland water supplies, it should be the duty of vending bodies to satisfy the Local Government Board, either that lead pipes would not be used, or that adequate and proper means would be provided and maintained to deprive the water of any dangerous plumb-solvent qualities."
Transactions of the Pharmaceutical Society of Great Britain.

MEETING OF THE COUNCIL.

Wednesday, March 6, 1885.

Present—

MR. MICHAEL CARTMIDGE, President,

MR. WILLIAM GOWEN CROSS, Vice-President,

Messrs. Allen, Atkins, Gostling, Grose, Harrison, Hills, Martin, Martindale, Newholme, Southall, Warren, and Young.

The minutes of the last Council meeting were read and confirmed.

THE LATE MR. BUBROUGHS.

The President read a letter which had been received from Mrs. Burroughs acknowledging the letter of sympathy from the Council on the death of Mr. S. M. Burroughs.

ELECTION OF MEMBERS.

Pharmaceutical Chemists.

The following having passed the Major examination, and tendered their subscriptions for the current year, were elected "Members" of the Society:

Athey, George Hedley ... Bothwell.
Butler, Ernest Charles ... Stamford Hill.
Elder, Alexander ... Cork.
Peach, Charles William ... Finsbury Park.

Chemists and Druggists.

The following who were in business before August 1, 1885, having tendered their subscriptions for the current year, were elected "Members" of the Society:

Johnson, Francis ... Prestwich.
Pottage, John Cooper ... Edinburgh.

ELECTION OF ASSOCIATES IN BUSINESS.

The following having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:

Ashfield, Percy John ... Crewe.
Barker, Robert Henry ... Windermere.
Boyce, Herbert George ... Forest Gate.
Brindle, Edward ... Edinburgh.
Campbell, Bernard Sidney ... Cambridge.
Dick, James ... Edinburgh.
Fray, Alexander ... Paisley.
Hartland, Charles ... Redditch.
Herbert, Henry William ... Egham.
King, James ... Coatbridge.
Letts, James Nair ... Sandbach.
Mitchell, Donald ... Inverness.
Morgan, Ebenezer ... Enfield.
Pratt, George Joseph ... Ilkerton.
Sanders, Ernest ... Manchester.
Watson, David ... Glasgow.
Williams, Hugh Francis ... Lianyfelin.

ELECTION OF ASSOCIATES.

The following having passed the Minor examination, and tendered their subscriptions for the current year, were elected "Associates" of the Society:

Armitage, Thomas ... New Shilton.

Cook, Robert ... Thornhill.
Lengden, Alfred ... Cheltenham.
Roberts, Edward Orchard ... Hampton.
Stoddart, Thomas ... Todmorden.
Tate, Anthony ... Durham.

ELECTION OF STUDENTS.

The following having passed the First examination, and tendered their subscriptions for the current year, were elected "Students" of the Society:

Adams, Ernest Charles ... Salford.
Atterbury, William Richardson ... Hampton.
Beresford, Arthur William ... Birmingham.
Boothroyd, Frederick ... Huddersfield.
Chapman, James ... Bathgate.
Cornfoot, Thomas Boots ... Faversham.
Goodall, Frederic Charles ... Congleton.
Goshawk, Alcock Henry ... Cheltenham.
Gowland, George ... New Castle-on-Tyne.
Gray, Clement ... Cambridge.
Green, Frederick Charles ... Havant.
Greenwood, Frederick ... Skggness.
Harrison, Sarah S. ... London.
Herbert, Alfred Walter ... Barton-on-Humber.
Howard, John B. ... Droit.
Hurst, James Vernon ... Birmingham.
James, Frederick ... London.
Johnson, Frank Horace ... Birmingham.
Jones, Morgan Richard ... London.
Kinder, John Henry ... Manchester.
Lawrence, Edmund William ... Knutsborough.
Lewis, Walter John ... Manchester.
McDonald, David Baird ... Glasgow.
Manfull, Frank ... Nottingham.
Morgan, David ... Llanesewel.
Morris, John ... Willington Quay.
Newy, Walter ... Stockport.
Normansel, John William ... Stockport.
Pretty, Clement John Robert ... Rye.
Robinson, John Newton ... Stockton-on-Tees.
Sellers, William Ernest ... Nafferton.
Stratton, John Fountaine ... Barton Bendish.
Todd, Arthur H. ... Belfast.
Tod, John ... Cheadle.
Ward, Wm. Henry Channell ... London.
Whittaker, Charles Edwin ... Manchester.
Wickens, Thos. Isaac James ... Southsea.
Williams, Joseph Miles ... Blaina.
Wilson, John Mitchell ... Irvine.
Wood, Edward Vivian ... Manchester.
Woolcock, W. James Uglow ... Newport.
Wright, Ralph ... Frodsham.

RESTORATIONS TO THE REGISTER.

The names of the following persons, who had made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:

John Westmacott Bedes, Lenham, Kent.
Edward Kent, 20, Royal Exchange, E.C.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a restoration fee of one shilling.

REPORT OF FINANCE COMMITTEE.

The Secretary read the report of this Committee, which recommended various accounts for payment.

The President (as Chairman of the Committee)
moved the adoption of the report and recommendations. The receipts on the General Fund account had been very small, but a good sum would be coming in shortly, the greater part of the subscriptions being usually paid in March and April. With reference to the payments, the only one to which he need call attention was £1000 to be placed to the credit of the Chairman of the Executive of the North British Branch, with a view to winding up the accounts for building and fitting up the new examination hall and laboratories in Edinburgh. Speaking roundly, the commission to the architect, the payment of the clerk of works, the introduction of a dado, and sundry other matters, such as the fittings for the electric light, substantially involved additions to the original estimate of between £400 and £500, and the remainder was for detailed work in connection with the examinations, including special fittings, scientific apparatus, materials, etc. Practically it might be said that £2500 had been expended on capital account, and £500 on apparatus and materials more or less consumable. A full statement would be presented later on, but the Committee had seen most of the details, and he did not think there had been any extravagance. It was always difficult to know exactly beforehand what such things would cost, and, as often happened, the plans had been somewhat improved as the work went on, with, of course, some additional expense. On the Benevolent Fund account several donations had been received, viz., from Major Probyn, £50; from Mr. Trickey, Eastbourne, 5 guineas, and from Mr. G. Richards, Hastings, 10 guineas, making £85 15s. in all.

The report and recommendations were unanimously adopted.

BENEVOLENT FUND COMMITTEE.
The report of this Committee notified investigation into three applications for relief. As to two of these it was recommended that they be not entertained, and with regard to the third, the Secretary was instructed to obtain further information.

The VICE-PRESIDENT (as Chairman of the Committee) formally moved the adoption of this report without comment, and it was agreed to.

REPORT OF THE LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

Library.
The report of the Librarian had been received including the following particulars:

<table>
<thead>
<tr>
<th>Attendance</th>
<th>Total.</th>
<th>Highest</th>
<th>Lowest</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td>January</td>

</thead>
</table>
| January | 223 | 11        | 109 £1 9s. 10½d.

Donations to the Library had been announced (Pharm. Journ., February 16, p. 697), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

Museum.
The report of the Curator had been received, and included the following particulars:

<table>
<thead>
<tr>
<th>Attendance</th>
<th>Total.</th>
<th>Highest</th>
<th>Lowest</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>

<td>2</td>
</tr>
</tbody>
</table>

Donations to the Museum had been received (Pharm. Journ., February 16, p. 697), and the Committee had recommended that the usual letters of thanks be sent to the respective donors.

This Committee recommended the insurance of the Society’s premises in Scotland against fire for £4000; £3000 in respect of the buildings and £1000 on the contents. It also recommended a grant of £25 to the Sheffield Pharmaceutical and Chemical Society, but was unable to recommend compliance with the request of the Inverness Chemists’ Assistants’ Association for a grant.

The PRESIDENT, in moving the reception and adoption of this report, said it was not necessary to call attention to the formal business, or to the consideration of the assurance of the new premises in Scotland. As to the application adjourned from a previous meeting to consider an application for a grant to the Sheffield Society, that Society was engaged in a scheme of education which had not been quite so successful during the last year. The Committee, after careful consideration, and having had the advantage of the presence of Mr. Newholme to give it information, had unanimously recommended a grant not of £50 but of £25, on the principle that probably local contributions might be forthcoming to make it up to the larger amount. The Inverness application could not be entertained, it being altogether informal and not coming within the scope of the Society’s regulations.

The Annual Report.
The preparation of the Annual Report was referred to the Library, House, and School Committees.

THE ANNUAL MEETING.
It was resolved that the Annual Meeting be held on Wednesday, May 22.

THE WEIGHTS AND MEASURES ACT AMENDMENT BILL.
The PRESIDENT said he had received a letter from Mr. Umney suggesting that as this Bill, introduced by the London Chamber of Commerce, had now been referred to a Select Committee, of which Sir Henry Roscoe was Chairman, application should be made for permission to give evidence from a pharmaceutical point of view. He had already been authorised to take such steps as might appear desirable for securing the passing of the Bill, and he would now move that the President and Mr. Martindale be appointed to give evidence on behalf of the Council on obtaining permission to do so.

The resolution was at once agreed to.

DEATH OF CORRESPONDING MEMBERS.
The PRESIDENT announced that two of the corresponding members of the Society had died during the past month, viz., Mr. Andrew Ferrel, chemist to the
Government Medical Department at Moscow; and Mr. Jean Edouard Bommer, Curator of the Botanical Gardens at Brussels. Both gentlemen were distinguished in their respective lines of work, and it was only right that some reference should be made to their loss on the minutes of the Society.

LOCAL SECRETARY.

Mr. Wm. Gregory of Weymouth, was appointed Local Secretary for that town.

The President said it sometimes happened that the Registrar, on behalf of the Society, had to make proof of deeds owing to it, and the solicitors advised that for that purpose it was necessary that a special resolution should be passed, and sealed with the corporate seal, giving him authority to do so. He therefore moved a resolution to this effect.

This was seconded and carried unanimously.

THE LAW AND PARLIAMENTARY COMMITTEE.

The Secretary read the minutes of this Committee, which had held two meetings, and had recommended that no Bill be introduced in the present session.

The President moved that the report be received and adopted. He was sorry to say that it had become necessary to report somewhat definitely in consequence of the state of public business in Parliament. They were all anxious to do certain things; they had promised their members to consider certain things—the question of the consolidation of the Society, the admission to membership of associates in business, the curriculum, the question of companies trading, and various other things were all under consideration waiting to be brought forward at a convenient time. He must say, speaking for the Committee, that after giving the whole subject full consideration, it was felt to be hopeless to move during the current session but the Committee in novia forgot their obligations to the many active associates in business who were doing such excellent work throughout the country.

Mr. Martindale seconded the motion.

Mr. Harrison said he regretted that he was not able to be present at the meeting of the Committee, and still more that it had been found necessary to come to the decision just reported. It would be idle to close one's eyes to the difficulties which exist, and even if an attempt were made to go forward he was not quite sure that it would be practicable; probably such a heroic effort would only end in smoke. At the same time he very strongly objected to an indefinite postponement of the matter. Though the Committee might be perfectly right in its decision, it would not, in his view, be right to postpone the further consideration of the question until the eve of another session; and he thought an early opportunity should be taken of formulating a scheme embodying what was generally demanded. It might then be issued to the members in time for them to consider at their autumn meetings what the Committee had been thinking over, with a view to the formation of a healthy public opinion on the matter, and creating some amount of enthusiasm in respect to it, so that when the Bill was introduced it might have some chance of success. He should like the Committee to meet again at an early date and formulate a scheme, or the same difficulty would occur again, besides, as the years went by it was evident Parliament became more and more impotent to discharge its duties. If he were re-elected on the Council he should certainly bring the matter forward again with a view, at any rate, to the consideration of the three Cs—curriculum, consolidation, and company trading; but he agreed that for the present they must await a more convenient opportunity of introducing the Bill.

Mr. Martin also regretted his unavoidable absence from the last meeting of the Committee, and agreed with Mr. Harrison that while the decision arrived at appeared to be inevitable, the idea of formulating a scheme ought not to be abandoned. There were many things which ought to be done, but at present the ideas of most people were in a somewhat nebulous condition, and he thought it was the duty of the Committee to endeavour to crystallise those ideas in the form of a Bill, whether there were any immediate prospect of introducing it or not, so that at any rate the members of their own body might be educated as to what the Council thought necessary, and if a general Parliamentary election took place during the year there might be some opportunity also of educating prospective members of Parliament. It was no use going to a candidate and saying you wanted something done, unless they were all fairly agreed on what they should ask for.

Mr. Atkins thought the Committee had acted very prudently. It might be desirable that the idea Mr. Harrison had thrown out should be adopted, and that the trade at large should be called upon to criticise some definite scheme and make suggestions, but he should certainly depurate the launching of a Bill without any immediate and definite prospect of its being introduced. The members got rather chary of being worried on these matters unless there was some definite action in view. He spoke from some experience in the matter, and he did hope that no move would be made until there was some prospect of something being done.

Mr. Southall agreed very much with Mr. Harrison's views, and expected from his remarks that he was going to conclude by moving that the Committee be instructed to prepare a Bill so that the members of the trade might be educated. A great many meetings were held from time to time in the country, and very often there was very little to discuss; but if a Bill were framed it could be discussed, and would give an opportunity for finding out what people really wanted. The three Cs which had been mentioned might all be usefully discussed, and though it was no use attempting at present to educate members of Parliament, the education of their own members was another matter, and he thought everything was to be gained by taking them into the confidence of the Council.

The resolution for the adoption of the report was then agreed to.

The President reported the receipt from Mr. Randall, Secretary of the Colonial Pharmaceutical Board
of Cape Town, of a copy of the "Pharmaceutical Register" of Cape Colony.

RESEARCH COMMITTEE.

A special report of this Committee was referred to the General Purposes Committee for consideration and report.

GENERAL PURPOSES COMMITTEE.

The report of this Committee was read and considered in Committee.

On resuming, the report and recommendations were unanimously adopted, and a special resolution passed authorising the Registrar to take proceedings against the persons named.

Proceedings of Societies in London.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At the meeting held on Thursday, February 21, the following paper was read:—

DIATOMS.

BY F. RANSOM.

(Concluded from p. 764.)

Diatoms present an endless variety in form and structure. The Naviculaceae, or boat-shaped genera, is one of the most common, and may be regarded as the type of the unattached varieties. It contains many species, but all are characterised by being somewhat pointed at each extremity and broader at the centre. Others are linear, oval, wedge-shaped, triangular, circular, etc., and the markages present an infinite variety of designs often of exquisite delicacy and beauty. These markings on the valves have received a large amount of careful examination, and many points respecting their structure have been explained. They have afforded material for long and patient research, and many theories have been suggested to explain their appearance. It would appear, however, that they are due to various forms of depressions and inequalities in the siliceous valve and that no general theory can be applied to every case. It is usually found that the striae or lines which are at first visible, are converted under higher magnification into rows of beads or perforations. Some interesting phenomena which might at first be supposed to throw some light on the construction of the diatom valve were investigated by Schulze with this object. As is well known, the addition of sulphuric acid to a mixture of powdered flour spar and sand causes the evolution of the colourless gas, silicon-tetrafluoride, which on coming into contact with aqueous vapour deposits silica in a very finely divided condition. On examining this deposit under the microscope it is found to consist of thin walled vesicles of various forms and sizes. The exterior of many of these exhibit markings very similar to those which are seen on the valves of many common diatoms. The results of Schulze's investigations, however, tended to show that the differences were greater than at first appeared, and he concludes that notwithstanding the apparent similarity the sculpturings of diatom valves and siliceous pellicles are in reality due to wholly different conditions.

The habitats of diatoms form a subject of much interest. Roughly, they may be divided into three classes, according to the water in which they are found. Firstly, there are the fresh-water species, including all those which exist in rivers, ponds or ditches, and, indeed, in any situation to which the sea has no access; secondly, the marine; and, lastly, a much smaller class which holds an intermediate position, and is found only in the brackish water of swamps and dykes, to which the sea has occasional access. Although species can be thus described as marine, fresh-water, or brackish, most of the common genera cannot be so distinguished, being abundantly represented both in sea and river.

In connection with the distribution of diatoms a remarkable feature is the great area over which most of the commoner species are to be met with. Brun remarks that he has found in Switzerland almost all those that have been recorded in Saxony, Austria, Central France, and the neighbourhood of Paris. The same might be said of Britain, whose recorded species include the great majority of those of Switzerland. I have collected specimens from the streams of the Pyrenees, the Alpes and the Riviera, and find nearly all to be recorded as British, and many to be common around London. The usual explanation suggested for their cosmopolitan nature is that in a dry state they are conveyed by the wind for long distances.

The size of fully-developed specimens varies greatly. Amongst the larger forms of British varieties some of the Synedra attain to the greatest length, S. crystallina, a marine form, is mentioned by Smith as measuring rather over 1/40th inch. On the other hand, various species of Achnanthes are frequently found to be only about 1/2500th inch in length. These dimensions refer, of course, to the single frustule; in those species in which the frustules remain attached to each other filaments are frequently found of considerable length.

In order to convey an idea of the extreme minuteness of some varieties Ehrenberg calculated that a space of a cubic inch could contain 40,000,000 specimens. He was probably unacquainted with the smallest forms, as the same space would contain over 3,000,000,000 frustules of Achnanthes.

Many diatoms possess a remarkable power of enduring great variations of temperature without injury, and of existing under conditions which are usually fatal to plant life. Brun relates that he has found living specimens in the melting snow of the high Alps, and it is known that they exist for months on dry rocks exposed to the heat of the sun. Under such circumstances all vital action is suspended, but as soon as the conditions are rendered favourable by the action of rain or sun the usual functions of life recommence, and no injury appears to have been sustained. Extraordinary cases have been reported by various observers of the power of diatoms to revive after being kept dry for a long period. Habibrahaw mentions a case of resuscitation after being kept without water for six years. I have moistened specimens of Synedra dried about four years previously, but could obtain no definite signs of life, although the colour of the endochrome was to some extent restored.
One of the most interesting phenomena connected with the natural history of diatoms is the power that many possess of independent movement, a fact already alluded to as a source of error to those observers who have classed them as animals. Various theories have been suggested to explain the method and nature of this motion, but nearly all come under one of the three following heads—firstly, the existence of endosmotic and exosmotic currents; secondly, the presence of cilia on some part of the frustule; and, thirdly, the action of some exterior or protruding protoplasm. The hypothesis that the movements are caused by osmotic currents, originated by Nägeli in 1849, was for some time the most generally accepted theory. That such currents do exist is to be expected, but that they are sufficiently powerful and varied to account for these propulsions is scarcely probable. The movements are described by the Rev. William Smith, who inclined towards the osmotic theory, in his "Synopsis of British Diatomaceae" as follows:—"This motion is of a peculiar kind, being generally a series of jerks, producing a rectilinear movement in one direction, and a return, upon nearly the same path, after a few moments' pause, by another series of isochronal impulsions. The movement is evidently of a mechanical nature, produced by the operation of a force not depending upon the volition of the living organisms. An obstacle in the path is not avoided, but pushed aside; or, if it be sufficient to arrest the onward course of the frustule, the latter is detained for a time equal to that which it would have occupied in its forward progression, and then retires from the impediment as if it had accomplished its full course." This is an accurate description of many of these movements, but the jerks are often absent, and it is frequently seen that considerable digressions are made from the rectilinear course without any apparent obstacle being encountered. It is also observable that the direction is to some extent mechanically regulated by the shape of the frustule as in the crescent-shaped Cymbella, whose course usually describes an arc of a circle. I have kept an active specimen of Pseudosigma under observation during a series of ten journeys, and found that they varied in time from sixty-two to a hundred seconds. Dr. Carpenter, in the sixth edition of his standard work "The Microscope," while stating that the cause is still obscure, appears to favour the osmotic theory, and endeavours to dispel the objection that such motion is not observable in other unicellular organisms by saying that there are no other such organisms which are so nearly surrounded by an impermeable envelope, and consequently in which osmosis is limited to so small a portion of the cell-wall. A serious objection both to the osmotic and ciliary theories is that contact with some foreign body appears to aid, if not indeed to be essential, to all the movements. If either of these theories were correct, it might be supposed that such contact would be an obstruction rather than an assistance.

The ciliary theory has now been generally discarded, although it has occasional revivals which create some sensation at the time of their appearance. The idea was first suggested by Ehrenberg from observations made on Surirella gemma, a common marine form, from the shell of which he maintained that long delicate threads projected, which the "creature" voluntarily drew in or extended. Thread-like processes, consisting of fungoid growth or parasitic Algae are not unfrequently met with, similar to those described, but that they have any connection with the movement of the frustule, beyond a tendency to decrease its speed, is not at all probable. A rather novel modification of the ciliary theory appeared in the American Monthly Microscopical Journal, for 1883, where a writer suggests that the cilia exist within the frustule and act against the current of water passing through.

The third hypothesis takes into account the presence of protoplasmic material exterior to the siliceous envelope, and has of late had many supporters, who, however, differ greatly in respect to details. Schultz, in an early contribution in support of this theory, considered that the interior protoplasm is protruded through the minute apertures of the valves, when it forms a sort of moving band, which, passing along the exterior of the shell, comes in contact with some solid body, and thus forces the diatom in the opposite direction. Professor Ray Lankester, referring to Schultz's paper, describes it as "ending in a satisfactory and conclusive explanation of the method and nature of locomotion in these organisms." A later writer, Anderdank, describes what he calls a "mobile pallium," which partially surrounds the frustule and imparts motion to it. That the final explanation will be found in connection with some protoplasmic material exterior to the shell is not improbable, but there seems no immediate prospect of a complete solution of the interesting problem.

Although the motion of diatoms is slow compared with that of many of the animal organisms with which they are found, it is not insignificant if regarded in relation to their size. The most rapid in movement is Bacillaria paradona, which Smith found to travel at the rate of about an inch in three minutes. Unlike most species with motile power, these diatoms do not consist of detached frustules, but a number of cells remain connected by the membranous covering. When first observed they may be arranged compactly side by side, then suddenly they extend into a long line, the frustules being attached only by the opposite alternata corners. The sudden transformation is a most interesting sight, and quite unlike the slow movements of other species. This diatom is usually met with in brackish water; I have found it in the ditches of marshy land near Pitses, which forms a happy hunting ground for the collector, and yields a variety of interesting forms.

Another subject of interest in connection with the natural history of diatoms is that relating to their means of multiplication. The simplest and most common method is self-division, corresponding with the ordinary cell-division as seen in all forms of plant life. The first step of the process appears to consist in the division of the nucleus of the protoplasm. This is soon followed by a growth of cellulose and the development of two fresh siliceous valves, similar in structure to those of the original
frustule, and growing opposite to each in the interior of the cell. As soon as these new valves are fully formed the frustule, if that of a free species, splits from end to end, and two diatoms result, each possessing one of the original and one of the newly formed valves. Under favourable conditions this process of self-division is estimated by Smith to occur once in about twenty-four hours. Assuming this to be correct, a simple calculation will show that in a month a single frustule might increase to about 1,000,000,000. A very rapid development of diatoms may often be observed in a puddle of rain-water which has remained undisturbed for a few days. As in many other lower forms of life, it appears that after a certain period, or after a certain number of subdivisions, this power of cell-division becomes exhausted, and Nature resorts to fresh means of continuing the species. A process of reproduction now takes place resulting from the conjugation of two frustules. The details of the process vary much in different species, but in each case the endochrome and protoplasmic contents of two frustules become united. This results in the formation of one or occasionally two auxospores, and from these a new generation is formed capable of multiplying by subdivision. Occasionally a similar result is obtained without conjugation by the enlargement of a single frustule.

In estimating the results produced by diatoms in the economy of Nature, we find that the imperishable character of the siliceous valves plays an important part. In most parts of the world where search has been made large deposits of so-called fossil diatoms have been discovered. Whether fossil is a correct term to apply to these remains when, as is frequently the case, they exist in a condition almost the same as when originally formed, is perhaps open to question. Occasional specimens are met with in recent geological strata, and they have been found to be present in the London clay, where a few species new to Britain were detected. Deposits of almost pure diatoms exist in the beds of several small lakes in North Wales, Scotland, and Ireland. In Norway and Sweden a remarkable use is made of deposits of this description, which are termed berg-mehl or mountain-fine. In bad times it is the custom of the peasants to mix this material with their dough in making bread, the idea being that it increases the nourishment. One of the best known and most remarkable diatomaceous deposits is in Virginia, where the city of Richmond is actually built upon a stratum, varying from eight to thirty feet in thickness, consisting almost entirely of the valves of marine diatoms of past ages. Another interesting source is guano, where we find that these indestructible shells have passed unburned through the bodies of sea-birds. Some new species were discovered in the stomachs of Japanese tinned oysters exhibited at the Fisheries Exhibition in London in 1883.

Diatomaceous earth is much used for polishing hard surfaces, a well-known deposit in Austria being of special value for this purpose. Owing to the extreme fineness of the valves a similar material has been used in the manufacture of dynamite, as-sufficing silica in a finely divided condition. A variety of this earth, known as kieselguhr, has been employed with success in the pharmaceutical process of filtration. The clarification of cloudy liquids may be assisted by the addition in the filter of a small quantity of powdered kieselguhr, and the filtration of comparatively thick liquids is often quickened by the same means. Besides these uses a most valuable service has been rendered by certain diatoms in providing tests for the quality of object-glasses. The lines or striae, which occur on the siliceous valves vary only to so small an extent on the same form that they may be employed as a standard. The number of these lines which can be rero'ed in a given space indicates with approximate accuracy the angular aperture of the objective, and hence its power of exhibiting detail may be correctly measured. Amphitheca pellucida, a species found in Britain, is largely employed as a test for this purpose.

A rather novel use was made of diatoms some years ago by Dr. Bossey, described in a paper entitled "Thames Mud in Relation to Sanitary Science." It is well known that large deposits of mud have been formed at various times in the Thames in the neighbourhood of Chelsea and elsewhere, and it became an important matter to determine whether these accumulations had any connection with the sewage matter discharged into the river lower down. With the view of obtaining some reliable information on this point, the diatomaceous forms from a number of these deposits were examined, with the result of finding numerous specimens of marine species even so high up as at Richmond. This indicated the power that the tide possesses of conveying solid materials far up the river, and suggested the probability that sewage matter may have had some connection with the formation of these banks.

Finally, I think we may claim that diatoms are of use from an educational point of view. The study of these minute forms of life cannot but stimulate those powers of accurate observation which are so essential to the success and enjoyment of life. The mounting of the valves as microscopic objects affords exceptional opportunities for the exercise of manipulative skill. Problems in connection with their power of movement, their reproduction, and the delicate markings of their frustules still remain unsolved, and offer to observers a promising field for further research.

In conclusion I desire to express my thanks to Mr. F. W. Phillips, F.L.S., for his kindness in lending me the series of illuminated diagrams in illustration of the subject of this paper.

A meeting was held on Thursday, February 28th, the President, R. H. Jones, in the chair.

The following papers were read:—

A METHOD OF PREPARING SMALL QUANTITIES OF AROMATIC WATERS.

BY C. R. SAGE.

The author had made experiments to see whether an apparatus could be devised in order to enable pharmacists to prepare their own aromatic waters. The apparatus consists of (1) a half-gallon tin (one that has been used for oils, etc., which has been
thoroughly cleaned) fitted with a cork in which are two tubes, one a straight tube dipping under the surface of the water and projecting some distance beyond the cork, the other tube bent at right angles and projects only a little way beyond the cork in the can; (ii.) a flask fitted with a cork containing two tubes bent at right angles, one reaching to the bottom of the flask, and the other just within the neck; (iii.) an ordinary condenser and a receiver.

The tin contains the water, which boils vigorously, and the steam passes by the exit tube into the second flask which contains the drug, where part of the steam condenses, and another portion passes over with the volatile constituents of the drug and is condensed in the usual manner. It is found that after a short time "spurt ing" commences, owing to condensation of the steam in the second flask, accordingly, a trap is used to prevent all solid particles from passing over. In this way one pint of aromatic water could be prepared in an hour, but, when the drug was used, the water was always found to possess a slight empyreumatic odour, and the author therefore suggests the use of the oil in place of the drug. When the oil is used, the second flask need not be so large, and there is no spurtling. Samples of waters prepared in this manner were exhibited.

A USEFUL LABORATORY FILTER.

BY ALEX. GUNN.

The filter was originally devised to minimise oxidation, and in this respect proved an unqualified success: it was also found very useful in filtering strong solutions of quinine in phosphoric acid, which went indifferently through funnel or twist, and refused absolutely to go through paper. The whole apparatus is in principle a syphon, the filter itself being simply an alteration in the limb of the syphon, adapted to hold the filtering medium.

The apparatus is constructed as follows:—a glass cylinder is taken about 12 inches long and 1½ inch in diameter. The supply tube, 1½ inch diameter, is connected to the cylinder by a rubber bung, and the exit tube, ½ inch in diameter, is connected in a similar way. It is important that the supply tube should be of wider bore than the exit tube, otherwise the limbs of the syphon will not be full. The filter is charged as follows:—the exit tube having been fitted to the cylinder, a few pieces of clean broken glass are inserted, then a waft of cotton wool, not tightly packed, to make a layer about ½ inch deep, then a little glass wool and more cotton wool as before, glass wool again, and then a layer of paper pulp.

The central space of the cylinder is filled with eight or nine small clean glass stoppers (ounce phial size), or glass beads if preferred. This prevents too much compression of the different layers. Paper-pulp is added next to form a layer 1 inch deep, solid but not tightly packed, a little glass wool over this, then another layer of paper-pulp, and finally a little more glass wool, and if there is room a pad of cotton wool. It is possible by using the arrangement described to filter 20 or 27 gallons in a night without any loss, but care must be taken that the receiving vessel is of sufficient capacity to contain the whole of the filtered liquid or disaster will ensue.

The following are some of the advantages in favour of the filter. Exposure to the atmosphere is reduced to a minimum; heavy sediments can be avoided by raising the limb of the syphon and so preventing clogging; there is no disturbance of the filter by addition of more liquid. It is self-feeding, and with suitable vessels requires no attention when once started; consequently filtration may proceed over-night, and the filter may be filled with any suitable material, such as charcoal, kieselguhr, etc., and can be easily changed or cleaned when necessary. Lastly, there is no waste of liquid.

The filter described bears a striking resemblance to a percolator described in a paper read before last year's British Pharmaceutical Conference, but the filter was in almost daily use in June of the same year, and this fact disposes of any charge of plagiarism that might be made.

PROVINCIAL TRANSACTIONS.

LIVERPOOL CHEMISTS' ASSOCIATION.

A general meeting was held at the Royal Institution on Thursday, February 28, Mr. Jno. Smith, President, in the chair. There was a large attendance of members, many of whom were attracted by the announcement that Professor Carter, in the course of his remarks upon "Argon," would exhibit the illness in the spectrum by the spectroscope. Owing, however, to an accident to the tube of argon, this was prevented.

Dr. Carter read a series of letters from one who has assisted Lord Rayleigh in his researches, which explained in considerable detail the progress of the investigation step by step.

The following papers were then read:—

NATURE'S POLYPHARMACY.

BY WILLIAM CARTER, M.D., B.SC., LL.B. LOND., ETC.
Professor of Materia Medica and Therapeutics, University College, Liverpool; Physician to the Liverpool Royal Southern Hospital.

As a not unnatural reaction from the great complexity of the older medicinal formulæ, there has been of late years an increasing tendency in the direction of what is termed simplicity in prescribing, till at length some physicians appear to shrink from ordering at any time more than one drug, lest they should be considered to sin against reason and nature; while in the practice of a very few medication has reached the vanishing point, and, rather than run the risk of polypharmacy, these prefer to have no pharmacy at all.

Extremes are always to be avoided. In this, as in every other department of knowledge where experience comes into operation at all, it affords the safest guide for action, and an increasing knowledge of the constitution of many of our old-established and best approved remedies proves that on that safe ground some degree of polypharmacy is justifiable, while a growing acquaintance with the great complexity of the chemical and physiological processes going on in the human body justifies it on the higher but less easily secured ground of scientific reason.
The constitution, chemical and physiological, of even the simplest unicellular organism—if it is not a misnomer to apply the term organism to that which seems to have no organs—is so complete that it is not possible to say, except as the result of experiment, how even it will react to drugs, while every step upwards in the scale of living beings presents such an increasing complexity, organ being added to organ, each with its distinct secretion and system to systems, that at last the mind becomes absolutely bewildered in its attempt to grasp the intricate workings of the whole. Our conceptions on this apparently simple but really most difficult matter of the reactions of our bodies to drugs are coloured by the belief that the personal identity, which makes us feel that morally and intellectually we are the same beings through many succeeding years of life, may be extended so as to embrace our physiological and physical beings as well.

If a man commits a breach of the moral or criminal law to-day, he will be justly amenable to whatever punishment such breach may entail, even if years shall have elapsed since the sin or crime was committed, and he would feel, and justly feel, that he is the very same responsible being in 1805 as he was in 1895; but if because of this just conclusion he thinks that he is so far the same being that he will respond to the same drugs in a similar way at the two periods, he is reasoning foolishly; for it is just possible that a really very great and fundamental change in his entire organism may have taken place in the interval. Not only is he not the same being in this lower sense of the term “being” at any two years of his life, but he is not the same at any two hours; for probably no more unstable or variable piece of mechanism than a civilised man is anywhere to be found in the world. The more highly civilised, or as we are apt to term it the more nervously constituted, he is the more and more unstable is he apt to become.

There is no more sensitive index of the chemical changes which are going on in the human body than the urine, and this is found to vary in composition from day to night, and even from hour to hour. Bouchard in his well-known experiments found that the urine of a healthy man, voided immediately after the usual night’s sleep, when injected into the veins of a rabbit, was not only more poisonous than the urine of the same man passed at the end of a hard day’s work in the open air, but that it was poisonous in a different way, the predominant symptoms in the first case being convulsant, but in the second coma-producing. It has even been thought possible that the alternating states of sleeping and waking may possibly be due to the gradual accumulation within the body of products which, acting on the nervous centres differently at one period, viz., night tend to overawe the brain with drowsiness, and at another, the morning, to irritate it into wakefulness, and call the sleeper back to life and activity. At any rate, the fact that chemical products have an entirely different effect on the systems of those within whom they are generated, according to the time of the day, makes it easy to understand how it is that a hypnotic always acts best when administered near the time of natural sleep, its effect being then added to those sleep-producing products formed in the natural laboratory of the body at that period; as well as why it is that convulsive movements will often occur in those liable to them as the time of ordinary waking is drawing near, and gives reason for the practice of doubling the dose of protective medicine the last thing at night.

But what relation have these facts to any facts of drug administration? Why, just this: that so complex and variable a mechanism will probably require a variable and complex treatment when it becomes disordered. The hackneyed rules which should guide the writer of prescriptions in order that the pharmaceutical preparation may act cito, tuto, et seuclance (quickly, safely, and pleasantly), generally direct that a medicinal formula may consist of basic, adjuvans corrigens, and constitutens, or the chief substance with which to cure that which assists it, that which corrects any unpleasant effect, and that which serves as its vehicle.

But they do not contemplate anything outside this, and modern ideas would be very much scandalised if a prescriber deliberately and of set purpose placed on paper in the same prescription the names of substances which were directly antagonistic to each other physiologically. He would be reproached for blowing hot and blowing cold at the same time, with being a mere empiric, with departing from the simplicity of science, and much more to the same effect. Yet probably such an objector would be very frequently guilty of the same kind of inconsistency as he criticised in others. For it is a curious and instructive circumstance that many of the great vegetable remedies, the efficacy of which has been established by years or generations of the experience of thoughtful and observant medical men, contain just such antagonistic principles. But a single name being given to the drug, its contradictory and compound nature is not thought of by those who prescribe it.

To a few examples of this kind of natural polypharmacy I desire to draw your attention, and if it can be established, as I believe it can be, that the effects produced by such a combination of opposite principles are good, that they are often much better than when either of the principles is given alone, there will be established a sufficient justification for the action of those who designedly introduce into prescriptions physiological antagonists, mixing them, however, in such proportions that the one shall moderate or control without entirely neutralising the activity of the other.

The first example which I will adduce is that of jaborandi. The leaves of this drug contain, in addition to a volatile oil, two absolutely antagonistic alkaloids, which, if they existed in such proportions that each could produce an equally powerful though opposite effect, would exactly neutralise one another and no result would follow. But the jaborin, or atropine-like alkaloid, is in so relatively small a proportion to the pilocarpine that it controls but does not destroy the effect of this latter. That it does control that effect is quite certain, and without any desire
to be singular or to affect a disagreement with those whose opinions are entitled to respect, I cannot help expressing my dissent from not a little of what is said and written concerning this drug. Thus, I find the following statement by a well-known authority: "Jaborandi appears, however, to irritate the stomach, and often causes nausea and vomiting, and so does pilocarpine, though to a less extent, even when subcutaneously injected."

My experience, which is large, would compel me to completely reverse the terms of this sentence by putting pilocarpine for jaborandi, and vice versa. So uniformly, indeed, did small doses (such, for example, as 3 grains) of pilocarpine nitrate cause vomiting when administered by the stomach that years ago I omitted to employ it in that way, substituting for it jaborandi as tincture or infusion, because it could be generally given without causing emesis. I do not say that jaborandi will never cause sickness, but what I do say is that it causes it very much less frequently than does pilocarpine, and that just as we sometimes designately introduce a small amount of atropine into our hypodermic dose of morphine, with a view of preventing the nauseating effect of the latter, even though atropine is to a certain extent a physiological antagonist of morphine, so nature in the case of jaborandi has effected the same kind of mixture of opposite alkaloids. I have sometimes had striking illustrations of the correctness of this statement.

In another respect the compound of opposites in this drug are superior to the pure alkaloid, it does not like that single alkaloid depress the heart. In the course of a celebrated criminal trial which took place some years ago in this city, a medico-legal expert, who admitted that he knew next to nothing of medicine as a practical art, expressed the opinion that the smallest officinal dose of tincture of jaborandi, of which I had advised the administration to relieve a distressing dryness of the mouth, would probably depress the heart; this, however, is just what it will not do, the jaborine and the alcoholic vehicle more than counteracting the depressing effect which pilocarpine alone might cause, either directly or indirectly through provoking sickness; and the admission that he had next to no knowledge of the practical effects of medicines seemed to me to be a perfectly needless one after such a statement.

Let me turn to another great drug in which a similar mixture of antagonistic principles is found. The British Pharmacopoeia contains digitale in three forms, 1, the dried leaf, 2, the tincture, 3, the infusion. Now the leaf contains several distinct principles, of which one—digitonin—is the direct physiological antagonist of the others. These last cause the small arteries, as well as the cardiac ventricles, to contract powerfully, and hence raise the general blood pressure, while the first, if pure, will, like saponin, with which it is nearly identical, cause them to dilate and the blood pressure to fall. But owing to its much greater solubility in water than some of the others, there is a relatively larger proportion of digitonin in the infusion than in the tincture, at least, such is said to be the case, and hence the contracting effect of digitonin and other principles that resemble it is more controlled and moderated by the infusion than by the tincture. If this is correct, it may help to explain what practical experience seems long previously to have settled, viz., the superiority of the infusion over the tincture in the treatment of acotic regurgitation, in which affection any undue amount of contraction of the smaller arteries would be a great disadvantage. I am quite aware that some object to the use of digitale in any form in acotic regurgitation, and that diagrams have been constructed to illustrate the manner in which it must do injury in this affection. Practical experience does not, however, support the validity of the objection. Digitale often proves most useful in this affection.

In the case of digitale, therefore, as in that of jaborandi, experience has established the fact that the blending of physiological opposites which nature has produced for us, is superior to either of the things blended when given alone; although any such intentional blending on the part of the subscriber would probably be characterised as the worst form of polypharmacy. I must add one word with regard to digitalis. Although I am willing to believe that the infusion may contain relatively more digitonin than the tincture, I am quite sure that a supposed rough proof of this which is often given is no proof at all. It is said that a given quantity of infusion of digitalis will, when shaken, froth more strongly and for a greater length of time than will an equal bulk of water into which has been poured an amount of tincture representing the value of the digitalis contained in the infusion. I can only say that when I have carefully performed this experiment as I have done, the very reverse has been the case. I can only imagine that the statement has gained currency by its having been accepted on the authority of him who first happened to make it without any attempt being made to determine its accuracy.

I will merely allude in passing to the fact that we have in physostigma such physiological opposites as physostigmine and calabarine, yet nobody objects on that account to using the extract.

If, however, we turn to the oldest and best of all the vegetable products of the Pharmacopoeia, opium, we find the most conspicuous example anywhere afforded in nature of this most despised, though in the present case most useful, polypharmacy. For besides gum, sugar, and other vegetable products, opium is said to contain no fewer than seventeen or eighteen different alkaloids, two neutral principles, and one peculiar acid, so that a prescriber of this drug, even though he may perhaps be flattering himself that he is conforming strictly with present-day notions of simplicity in pharmacy, is a polypharmacist of the worst and most pronounced type. And not only are the constituents of opium very numerous, but, like the other drugs mentioned, it affords in its thebaine and morphine a further illustration of direct physiological antagonism. Yet every practical physician knows full well that he can often obtain much more satisfactory results from that natural mixture of many principles known under the name of opium.
than from any single alkaloid which may be separated from it.

In conclusion, I should like for a moment to direct your attention to an example or two of polypharmacy of a pre-eminently useful character, though much despised by many who have never taken the trouble to prove its worth. Here is a prescription of the late Dr. Graves: B-Pulv. jalaeae, Pulv. rhei, Pulv. scamomlii, 2 gr. v., Helaterii, gr. iss., Pot. bitart., Pot. sulphatis, 5 gr., Syr. Zingib., q.s. ut flat bolus. This Dr. Graves used to treat, and well treat, as he tells us, many dropiscal patients. I can fancy the sourful curl of the lip of the very clever young pharmacological student of to-day as he casts his eye over this prescription, in which quick purgatives and slow ones, watery and simple ones, those which require an admixture with bile to ensure their activity, and those which act equally well when injected into the blood, are all jumbled up together and finally massed into a bolus big enough for a horse; and if it happens to be as humane as he is scientific, the contempt for such old-fashioned prescribers as Graves will be blended with pity for the poor people who grew dropiscal before the days when a minute powder of elaterium, perhaps even a minuter pillule, and that pillule a sugared one, as representing what is termed the elegant pharmacy of the present time would cure them cito, utu, et juvande. If I had the misfortune to be generally dropiscal, and could be permitted personally to choose between two methods, I should certainly select the bolus. By that means I should feel sure that a complete evacuation of my intestinal contents, and not a mere watery discharge, would be effected. Whereas, by the other method, I should feel almost as sure that while my small intestines were gradually undergoing contraction, till at length they would scarce be of greater girth than my thumb, my large intestines would be gradually distended by a compact solid fecal residuum, which no effort of mine, even if my strength were normal instead of at the lowest ebb, would enable me to evacuate. This is just what I have seen after the elegant method has been followed, but is just what Dr. Graves's prescription was designed and is effectual to prevent.

I will merely mention one other remedy compounded of many drugs which those who do not know its value despise, and which those who do know its value will never consent to be beyond the reach of. Warburg's tincture has formed the subject of many controversies. There was one in 1873, when Professor Maclean published a formula for it, when it was known that quinine, aloes, rhubarb, angelica seeds, saffron, fennel seeds, prepared chalk, gentian root, cubebas, myrrh, and camphor formed only some of the constituents. You may imagine the mirth that was excited in the minds of the scientific scoorners.

I will only say that I suppose we, at the Royal Hospital, have the opportunity of acquiring as large a practical acquaintance with the various types of malignant fevers as can be acquired in any hospital in the kingdom.—the Dreadnought, perhaps, alone excepted—and my opinion has long been that in some of the more dreadful of these fevers, such as those termed bilious remittent, where deep jaundice, high temperature, delirium, hemorrhage, etc., form such a combination of symptoms as would seem almost to shut out the possibility of hope, life has again and again been saved by the administration of Warburg's tincture, administered in Warburg's manner, and would have been saved by no other means as yet made known to us. I quite admit that the vast majority of such agues as we see in Liverpool do not require it. I do not know which, if any, of the numerous ingredients are useless, and until I do know this, I prefer not to omit any. And, lastly, I am ready to make the unmanly admission that if I ever should be my lot to be the subject of one of those terrible remittents or intermittents to which I have alluded, I should manifest a weak bias towards being cured by Dr. Warburg's polypharmacy rather than being allowed to die according to the strictest rules of nineteenth century scientific pharmacology.

**NOTE ON A SAMPLE OF CRYSTALLISED SUGAR.**

BY HAROLD WYATT, JUN.

Some time since I was asked if I could account for some crystallised sugar giving a distinctly blue coloration to milk with which it had been mixed. The sugar was of the ordinary white variety in rather large crystals, and had the appearance of the foreign made sugars produced from beetroot; but when viewed on a white background the crystals were of a more decidedly bluish shade than usual. The smaller particles and dust were full of dark specks easily seen with the naked eye, and on dissolving in water, a deep blue solution was formed. Knowing that it is a usual practice to face loaf sugars with a little smalts or ultramarine blue, I treated the solution with hydrochloric acid, expecting to perceive traces of sulphuretted hydrogen if the smalts blue were the colouring matter employed. The result was that the solution became yellowish, but no colour was produced. It then struck me, bearing in memory a recent case in which so-called Demerara sugar turned out to be a moist sugar coloured with brown aniline dye, that some aniline dye was the colouring matter, so I hung some floss silk in the solution, and in a few days saw by the absorption of the dye by the silk that my opinion was correct. The dye had evidently not been put into the syrup before crystallisation, but had been rubbed down with some of the sugar and then sifted through the crystals, showing that the "improvement" in colour had most likely been made by the broker and not by the manufacturer.

**NOTE ON SUPPORTORTES.**

BY HAROLD WYATT, JUN.

The most tiresome suppositories to make are, as most dispensers readily own, those containing vegetable extracts, requiring as they do such careful manipulations and unremitting attention. The usual mode of procedure consisting in thinning the extract down to a syrupy liquid, and adding this to the melted cacao butter, kept at as low a temperature as possible—is very well when one's attention is not distracted during the process, but the constant stirring necessitated makes the method,
at its best, somewhat irksome. Whilst in a situation in a French pharmacy I was shown by my worthy "patron" a little "tip" in the manipulation of such suppository masses which has been exceedingly useful to me since, and one indeed which I have extended to suppository masses generally, with the very best results. It is simplicity itself, and resolves itself into the use of a wide-mouthed bottle (fitted with a good cork, or better, an India-rubber stopper) instead of a small capsule or suppository water-bath. The cacao butter is put into this bottle, warmed on a water-bath until liquefied, and then the thinned extract or other medicament added, the whole being shaken vigorously until ready to pour into the moulds. It is easy to get as much as 5 grains of extract into a 15 grain suppository in this way, a thing rather hard to do in the usual fashion.

**Librius and Notices of Books.**

During the last few years a number of excellent books on elementary organic chemistry have appeared in which the method of treatment adopted, in most cases, has been to select a few typical compounds for detailed description as illustrations of general principles. The authors of the present work have somewhat extended this excellent plan, without, however, reducing it to a mere catalogue of organic substances. The scope of the book includes such subjects as aceto-acetic and malonic ether syntheses, oximes, hydrazones, diiso-compounds and their derivatives. Throughout the whole book constitutional and graphic formulae are freely employed, ample proofs being clearly given. Practical directions are given for carrying out a large number of experiments, the authors rightly insisting upon the importance of the student performing for himself the synthesis, analysis, purification, etc., of typical organic compounds.

Part I., comprising sixteen chapters, and about half the total number of pages, is devoted to the methane derivatives. In the introductory chapters the composition, purification, and analysis of organic bodies are described at considerable length. Then follows a chapter on the deduction of formulae from analytical results and determination of molecular weight, the cryoscopic and other methods being clearly described, and illustrations being given of the apparatus commonly used.

At the end of most of the remaining chapters a summary and extension is given in smaller type, the consideration of which the authors recommend the beginner to defer until he has acquired a general acquaintance with organic chemistry. In the extensions the more complicated reactions are placed, notably in the case of aldehydes, ketones, and carbohydrates.

Part II. consists of nineteen chapters, and embraces the benzenes or aromatic compounds. The opening chapter contains an account of the production of coal tar and the separation of its chief constituents on a commercial scale. The constitution of benzene is treated very fully, the prism, centri, and diagonal formulae all coming in for discussion. Naphthalene, anthracene, phenanthrene, the quinones, pyridine, and quinoline are also selected for detailed treatment.

Chapter XXXIII., dealing with the alkaloids, should be particularly interesting to students of pharmacy. The constitution of the most important ones is described as simply as possible, and a good deal of information in connection with this subject not usually found in an elementary text-book is contained in the chapter. Chapter XXXIV. treats of dyes and their application. The dyes are classified and the special character of each class in relation to its practical application to various fabrics is given.

Chapter XXXV., on stereo-isomerism, completes the book, which deserves to take a foremost place as a student's text-book in this country. Besides the systematic or theoretical treatment of the subject, the authors have included a large amount of interesting information in connection with the practical application of organic substances in commercial and industrial processes.

**Correspondence.**

**The British Pharmacopoeia.**

Sir,—In your issue of February 9, your correspondent "Galen" takes me to task for having used the word "tabloid" in my article in the British Medical Journal of February 8, and reprinted in the Pharmaceutical Journal of February 9. I regret that I was quite unaware that the word was a registered trade-mark, and, as I found that in 'Martin's Extra Pharmacopoeia,' seventh edition, mention is made at p. 146 of Cocaine Tablets prepared with chocolate, and at p. 148 of Tabloidor of Hydrochlorate of Cocaine for hypodermic injection, I imagined in my ignorance that I should indicate the kind of preparation I intended more exactly by the word tabloid than by tablet. I have no desire whatever to foster either quackery or monopoly, and if the General Medical Council will introduce general directions for making up suitable drugs into tablets or tabbils, your correspondent's troubles will be lessened or removed. But much more serious charges are brought against me in the leading article of your Journal of February 23, in which you have done me the honour of noticing my paper, for in it I am said to take up a position which is "very untenable," and am accused of using "arguments which are 'fallacious in the extreme.'" I am quite ready to renounce the position I have taken up as soon as it is shown to be untenable, and to throw aside at once any argument that is proved fallacious. But in your article you merely start with the assertions I have quoted, and you bring no evidence in support of them. The title of my paper and the statement in the leading article at p. 357 of the British Medical Journal (February 3), that it is the first of a series to be published in that journal dealing with the Pharmacopoeia from various points of view, show that my position is not that of a judge summing up the whole question of what the British Pharmacopoeia is or is not to be, but that of an advocate presenting one view of the case, viz., that of the prescriber; you bring forward no evidence what-
ever to show that this position is untenable. Acting as the advocate of the prescriber, I state that the Pharmacopoeia issued by the General Medical Council is intended primarily for medical men. This statement you grant to be correct (p. 711, column 1, last line). You then pass on to consider the relation of the Pharmacopoeia to pharmacists—a most interesting question, but altogether apart from the subject of my paper. I feel strongly myself, and I have also tried to persuade others that if the British Pharmacopoeia is to be up to the mark, it can only become so by the help of pharmacists, and I am glad if my paper has afforded evidence in support of this view; but this subject was outside of the scope of my paper, and was, consequently, not touched upon. The reasons I give for the greater popularity with medical men of Squire's 'Companion' and the 'Extra Pharmacopoeia' than of the British Pharmacopoeia are that they omit much matter which is not wanted, and that they supply some information which is wanted by the prescribers regarding 'the preservation of medicines and different modes of prescribing them in a more or less agreeable form, as well as hints or even fairly full statements about their actions and uses.' It must be remembered that the reasons given are for the popularity of the works not amongst pharmacists but amongst medical men. I have given them as the result of inquiries made amongst medical men, as well as of my own experience, and I should be glad to know in what respects they are 'not valid.' In my paper I acknowledge that the introduction of indications of the actions of medicines into the British Pharmacopoeia would be an innovation hardly to be hoped for, yet the expressions of opinion I have heard since my paper was printed justify me in the statement I made, that such an innovation 'would be warmly welcomed by many a medical man.' From the emphatic statement contained in your article, such an innovation would appear to be most pleasing to pharmacists, and it will be the duty of the General Medical Council to take into consideration the wishes and interests of all those concerned in the new edition of the British Pharmacopoeia, and decide accordingly. I should not have troubled you with this letter, but I have felt it necessary to defend myself from the charges which you have in your article brought against me of taking up a position which is 'very untenable,' of bringing forward reasons which are 'not valid,' and of making use of arguments which are 'fallacious in the extreme.'

T. LAUDER BRUNTON.

* * * Though we cannot share Dr. Lauder Brunton's opinion that the British Pharmacopoeia should be made a compendium of miscellaneous information, we regret that he should, therefore, have felt compelled to defend himself as the advocate of prescribers. If his efforts in that capacity were directed to ensuring a more rational exercise of the art of prescribing than is too frequently met with, we do not doubt that they would be productive of great advantage, not only to prescribers themselves, but also to their patients and to the dispensers of their prescriptions. —[Ed. Pharm. Journ.]

THE MAJOR EXAMINATION.

Sir,—Will you kindly allow me space to echo the sentiments of "M.F.C.S." in your last issue, re the passing of the Major examination by instalments, and to thank that gentleman for one of the best suggestions that I have lately seen in your Journal. If the above suggestion is adopted, possibly the Council of the Pharmaceutical Society will be able to make some slight concessions to those who were associates in business before the jubilee of the Society, as a mark of appreciation of their support as associates. Such an inducement would undoubtedly have the effect of largely increasing the membership of the Society—as there would be very few who, after having belonged to the Society for years, would sever their connection with it after having attained the higher qualification—and possibly induce outsiders to join when they see that the Society does something for those who have remained true to it, and so make the Society a truly representative body.

VERRATUM.

"SHOULD DOCTORS DISPENSE?"

Sir,—"Omega," in his letter to you of March 2, writes: "We chemists have not the right to prescribe." May I ask "Omega" where he has found that piece of law which disqualifies a chemist from enjoying rights common to all citizens of the United Kingdom? I was not aware that I signed away my prospective rights as a citizen when I signed my indentures. The law, as stated by a London stipendiary magistrate, and confirmed by a late Lord Chief Justice of England (Cockburn), was that doctors had no monopoly as to prescribing, anybody might prescribe. I think it would be better to cast aside all the miserable cant and face the matter fairly. Doctors dispense because it pays them well to do so; they thereby secure a fee whenever the patient requires a repetition of the medicine. The chemist prescribes because he cannot secure the prescription. He is surrounded by doctors who dispense their own except during an epidemic such as the present influenza, when they have not the time. There are a few exceptions, and I very carefully avoid prescribing for their patients.

London.

ALPHA.

REVISION OF THE BRITISH PHARMACOPEIA.

Sir,—In reference to the suggestion of "Devonensis" (p. 729), to omit the cypher in a few sp. gravities, I would suggest that, in an approximation, as a sp. gravity always must be, the cypher may be a significant figure indicating that the calculation has been carried to the third (or fourth) place with negative result. For instance, 1·065 indicates a value between 1·065 and 1·066; whereas 1·066 only gives latitude between 1·066 and 1·0665.

Tunbridge Wells.

S. O. REDMAN.

Answers to Correspondents.

"Constant Reader."—The former explanation is the one usually given, but it is conceivable that the second factor might come into play in some cases.

W. A. Grace.—Thanks for enclosure. The case illustrates several points of interest.

Corrections.—In the report of the Chemical Society's meeting in last week's Journal, the name of Professor MacLeod appeared amongst the auditors instead of the members of Council. On page 78, column 2, line 11, also, the word "reducing" appears instead of "oxidising." In Mr. Lusan's paper also, on page 79, column 1, after ascanitidines delete the words "to up," and in column 2, for Amaryl Nitrae read Aregni Nitrae. As already noted, on page 799, column 1, line 38, for "shall" read "still."

STANDARDISED PREPARATIONS OF BELLADONNA.

By R. A. Cripps, F.I.C.

The subject of this paper is by no means a new one; several investigators have already carried out valuable work and made suggestions which have been more or less practical.

Means. Dunstan and Ransom contributed to the Ph. J. [3], vols. xiv., xvi., and xvi., several papers, in which they described accurate processes of assay for the root and leaf, and their alcoholic extracts.

Their results indicated that the alcoholic extract of the root, as met with in commerce, was at that time extremely variable in alkaloidal value, nine samples yielding from 1-65 to 4-45 per cent., average 2-39 per cent. They strongly advocated the use of the root alone for all preparations of belladonna, the leaf and its extract being much less convenient for assay. They would exhaust the root by means of a mixture of rectified spirit and water in the proportion of four to one by measure, assay the resulting tincture, evaporate to dryness and add sufficient sugar of milk to bring the whole to the strength of 2 per cent. alkaloids, finally reducing to powder. From this the liniment and tincture could be prepared by solution in spirit of the same strength (1 to 1) in such proportions as to contain 0-2 and 0-034 part in 100 fluid parts respectively.

Ransom (Ph. J. [3], vol. xvii., p. 257), found samples of liniment to contain from 0-067 to 0-724 part of alkaloids in 100 fluid parts, average 0-19 per cent.

Cowie (Ph. J. [3], vol. xxi., p. 631) records the assay of six commercial samples of the root extract, which showed a range from 1-6 to 4-0 per cent., average 3-2 per cent.; moreover, he suggests 4-0 per cent. as a "standard."

J. Barclay (Ph. J. [3], vol. xxiii., p. 740), in a very valuable contribution to the subject, advocates a "standard" of 3-0 per cent. for the alcoholic extract, which he would prepare by first percolating the root with rectified spirit, then with a mixture of equal parts of natural spirit and water, evaporating each to an extract, assaying separately and mixing in correct proportions. The remainder of the weak extract he suggests should be raised to the strength of 1 per cent. alkaloids by addition of the strong extract q.s., and this might replace the present official extract. The liniment and tincture he would make to contain 0-25 and 0-025 part in 100 fluid parts respectively. His paper contains a useful table of results obtained by analysis of the root—twenty-three samples, extending over a period of five years, showing an average of 0-49 per cent., nearly all of which contained upwards of 0-40 per cent. Six samples of the commercial tincture yielded an average of 0-018 part in 100 fluid parts, and seven of the official green extract from 0-77 to 1-24, or an average of 1-00 per cent.

Farr and Wright, in their well-known researches on tinctures, examined twelve samples prepared by themselves from English and German leaves, the average being nearly 0-025, the English samples 0-028, German 0-017 part in 100 fluid parts.

A. Smith (Ph. J. [3], xvii., p. 856) examined three samples of the commercial success, and found from "a trace" to 0-05 per cent.

Collecting these various results together, we find the following averages and suggested standards:

<table>

Taking Barclay's figures for the root, and assuming an average yield of about one-eighth of alcoholic extract, the following would be the average strength of such extract for each year:

<table>
<thead>
<tr>
<th>Year</th>
<th>Average Yield</th>
<th>Per cent.</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Average of five years, 3·84 per cent.

It would thus seem that the evidence from their own figures, as well as Barclay's, goes to show that Dunstan and Ransom's standard of 2 per cent. for the alcoholic extract is too low, whilst Cowie's is too high; in fact, Barclay's would be about as reasonable a figure as could well be adopted, certainly not too high. It is, however, a very important question whether the alcoholic extract is really the most satisfactory starting point for a series of standardised preparations of belladonna. Wright and Farr, at least in so far as tinctures are concerned, strongly object to extracts in general for this purpose, and they are supported by Martin and others, the objections being chiefly:

1. The exposure to heat changes some of the constituents of the drug, so much so that the extract does not dissolve to a clear tincture, which tincture is also darker in colour and more liable to deposit than if made direct from the crude drug.

2. The extract may not contain the active principles in the condition in which they naturally exist on account of the prolonged heating.

3. Few extracts long remain in the same condition of dryness, etc.

4. There is needless waste of time.

They, therefore, advocate the preparation of a strong tincture as the starting point for standard tinctures in general. In so far as belladonna is concerned, the second objection has, I think, little ground, but the third is of peculiar force. If a jar of the alcoholic extract be left in a moist atmosphere for a single day only, it will be found in a semi-liquid condition on the surface. To put this into actual figures I left 226 grains of the extract for three days in a moderately damp place; at the end of that time it weighed 240 grains, corresponding to a gain of 5·8 per cent. The colour also of liniment or tincture prepared from an extract is very much darker than that made by B.P. process. This matter of colour is by no means improved by Dunstan and Ransom's suggestion of a powdered extract, although if kept in a tightly-closed bottle this expedient partially avoids the difficulty of deliquescence.

It seemed to me, therefore, that experiments were desirable in order to ascertain whether:

Vol. LIV. (Third Series, Vol. XXV.), No. 1880.
use of spirit of other strength than that employed by Barclay would yield a less deliquescent extract, or failing that (2), whether a liquid extract could not be prepared sufficiently strong to serve for the preparation of the liminent and tincture by dilution, and yet containing a sufficiently small proportion of "extractive" to serve for production of the alcoholic extract, etc.

There are two other objections to the extract prepared by Barclay's process, viz., such an extract contains so much mucilaginous matter that it requires a good deal of rubbing with the spirit to be satisfied that all the alkaloids have been removed from the insoluble portion, and the extract obtained by weak spirit requires a rather more complicated process for its assay, owing to this same mucilage.

Four experiments were therefore made on the first point as follows:—Four separate quantities of half a pound of the root in No. 20 powder were moistened with 6 fluid ounces of spirit, sp. gr. 0.833, and after standing all night, packed firmly in a percolator. Fourteen fluid ounces more spirit was now poured on in successive quantities of four ounces, after which the separate percolators received one pint of spirit of varying strength, as under:

| No. | Mixture of spirit and water | Pint of Spirit | Percolation stopped when 18 fluid ounces of percolate had been obtained from each, which was then evaporated to an extract—Nos. 1, 2, 3, 4.

Water was then poured over contents of percolators until one pint of weaker tincture had been obtained from each, which was also evaporated for extract—Nos. 1a, 2a, 3a, 4a.

Each of these was weighed and assayed, the results being recorded in the following table:

<table>

</table>

It will be seen from these figures that the total amount of alkaloids extracted by Barclay's method No. 4, and by the stronger spirit (3 to 1) used for No. 1 is practically the same, but that the actual yield of 3 per cent. extract is greater in No. 1.

Each of these was now mixed in proportions to form a 3 per cent. extract, and kept in a covered jar for a few days; in every instance a considerable amount of moisture had been absorbed, rendering the extract quite soft for some depth below the surface.

The next step was to endeavour to produce a strong liquid extract, and for this purpose two pounds of the root (containing 0.60 per cent. of alkaloids) was divided into four equal parts and treated by re-percolation with a mixture of spirit and water, 4 to 1, reserving the first sixteen fluid ounces of percolate from the final percolator, and also a second portion of sixteen fluid ounces.

Each of these was assayed and found to contain in 100 fluid parts 786 and 1/104 respectively, representing 78.6 and 10.4 per cent. of the actual alkaloids present.

When mixed with rectified spirit this liquid extract produced a very considerable precipitation. It was therefore thought desirable to use a rather more strongly alcoholic menstruum, consequently 1 lb. was similarly treated in four portions, with a mixture of rectified spirit 7, water 1, by measure, reserving 12 fluid ounces. This extract contained 0.73 per cent. alkaloids in 100 fluid parts. It was found to be far better for the production of the limiment, but formed a still more satisfactory mixture on the addition of a small proportion of water.

Having thus proved that a sufficiently strong liquid extract can be easily prepared, the next step was to settle the standards of strength, and then to devise satisfactory formulae for the various official preparations.

The root itself should, I think, be required to contain from 0.4 to 0.11 per cent., limits between which it will be easy to find plenty of bales. In my experience it may contain anything from 3 to upwards of 10 per cent., but seldom above 6 or much below 4. The German root is not inferior to the English, and should by all means be allowed.

The leaf it is quite unnecessary to retain for the preparation of the tincture, the dose of which, being but small, it will not materially alter the colour of mixtures to use a root tincture; however, I would, solely on account of its very extensive use, retain the present extract, but also wish to introduce a standardised powdered root extract of similar strength, so that in time the survival of the fifteen would determine which is to remain official. My experience of the assay of the official extract is in accord with Barclay's, the average being near to 1 per cent., rather below than above.

The success, so far as I know, and several pharmacists having large dispensing businesses tell me the same, is very little prescribed, and consequently would be of no great loss if deleted from the Pharmacopoeia; in common with the extract it cannot readily be standardised.

The alcoholic extract, as referred to above, should contain 2 per cent.

The limiment might contain 0.25 part in 100 fluid parts, this being more in accord with the proportion in the root than Ransom's suggested 0.20 per cent.

The tincture, as recommended by Farr and Wright and Barclay, might be one-tenth of the strength of the limiment.

In addition to these official preparations, the glycerin is largely used, and will probably be official in the next issue of the Pharmacopoeia; it could be made from the liquid extract so as to contain 5 parts in 100 fluid parts.

If these standards be accepted, the most convenient strength for the liquid extract will be 0.75 part in 100 fluid parts, and the following will be the formula of a full list of standardised official preparations, including the glycerin and powdered extract, as suggested above:—
**Eupatorium Belladonna.**

**Take of—**
- Liquid extract of belladonna.............. 4 fl. ozs. or 100 C.c.
- Resin plaster* Of each 24 ounces or 62½ grammes.

Evaporate the liquid extract of belladonna by the heat of a water bath until it is reduced to 1 ounce (or 25 grammes), then add the plaster, previously melted, and mix the whole thoroughly together.

It contains 0.5 per cent of alkaloids.

**Extractum Belladonnae Alcoholicum.**

**Take of—**
- Liquid extract of belladonna............. 21 fluid ounces, or 1060 C.c.
- Sugar of milk
- In powder .... a sufficiency.

Take 1 fluid ounce (or 50 C.c.) of the liquid extract of belladonna, evaporate it in a tared dish over a water bath, until it is reduced to a moderately firm extract, and weigh. The difference between the weight of the extract and ½ ounce (or 12½ grammes) will give the amount of sugar of milk required for 1 fluid ounce (or 50 C.c.) of the liquid extract:

Distil off the spirit from the remaining 20 fluid ounces (1000 C.c.) of liquid extract, add the required amount of sugar of milk as shown by experiment, and evaporate over a water bath to a firm extract, which should weigh 5 ounces or 250 grammes.† This extract will contain 30 per cent. by weight of the alkaloids of belladonna:

**Extractum Belladonnae Liquidum.**

**Take of—**
- Belladonna root in No. 20 powder...... 2 pounds or 1280 grammes
- Rectified spirit,
- Distilled water, of each a sufficiency.

Divide the belladonna root into four equal portions, and damp the first with 6 fluid ounces (or 240 C.c.) of a mixture of 7 fluid parts of rectified spirit with 1 fluid part of distilled water; allow to stand in a covered vessel for six hours, then pack firmly and uniformly in a percolator. Pour over the surface of the powder 4 fluid ounces (or 160 C.c.) of the same mixture of spirit and water, and when the liquid has been poured off, to drop close the lower orifice of the percolator and allow to macerate for twenty-four hours. Now continue slow percolation, adding more of the same menstruum as required, and use the first 6 fluid ounces (or 240 C.c.) of percolate to damp the second portion of belladonna root. Collect now the percolate in fractions of 4 fluid ounces (or 160 C.c.) each, or less, and having packed the second portion of moistened root in another percolator, use the fractions of percolate successively for its extraction, carrying on the operation exactly as in the first percolator. The first 6 fluid ounces (or 240 C.c.) from the second percolator is used to damp the third portion of powder, and this system of re-percolation is carried out through the whole series of percolators. Reserve the first 12½ fluid ounces (or 500 C.c.) of percolate from the fourth percolator and recover the spirituous liquor from the marc by displacement with water or pressure.

* This is rather weaker than the present emplastrum, in the proportion of 5 to 6; the official plasters are frequently complained of as being too strong.

† That no loss occurs was proved by direct experiment, 3°06 being obtained instead of 3°13 by theory, a difference within limits of experimental errors.

This weaker percolate may be used instead of fresh menstruum when again preparing the liquid extract, or it may be concentrated to an extract, dissolved in rectified spirit, and added to the reserved portion of percolate.

Determine now the proportion of alkaloids in the reserved percolate by the following process:

Introduce 10 C.c. into a separator, add an equal volume of chloroform with 50 C.c. of distilled water and a decided excess of solution of ammonia, agitate and set aside for the liquids to separate; draw off now the chloroform and agitate the aqueous liquid with another 10 C.c. of chloroform, drawing off as before; repeat a third time, and reject the aqueous liquid. Agitate the mixed chloroform solutions thoroughly with 5 C.c. of dilute sulphuric acid, mixed with twice its volume of warm distilled water; separate the chloroform, and agitate with a second portion of acidulated water. Wash the mixed acid liquids with a little chloroform, then agitate vigorously with 10 C.c. of chloroform and an excess of solution of ammonia, drawing off the chloroform when it has separated. Repeat this agitation and separation twice with half the quantity of distilled water, draw off into a tared flask or dish, evaporate, dry, and weigh. Dissolve now the alkaloidal residue in 10 C.c. of NaOH at 30°, and finally add 100 C.c. of till neutral, using myrtyl-orange or iodine as indicator. From this calculate the amount of alkaloids 1 C.c. NaOH at 100° being equivalent to 0.0289 Gm. of atropine. This should correspond closely with the amount found by weighing.

Add now to the remainder of the reserved percolate sufficient of the original menstruum to produce a liquid containing 0.75 part of alkaloids in 100 fluid parts.

**Glycerinum Belladonnae.**

**Take of—**
- Liquid extract of belladonna.............. 4 fl. ozs. or 100 C.c.
- Glycerin .... a sufficiency.

Evaporate the liquid extract by the heat of a water bath until it is reduced to a soft extract, then add sufficient glycerin to make the whole measure 6 fluid ounces (or 150 C.c.), mixing thoroughly.

One hundred fluid parts will contain 0.5 part of alkaloids of belladonna.

**Linsimenum Belladonnae.**

**Take of—**
- Liquid extract of belladonna.............. 10 fl. ozs. or 250 C.c.
- Camphor....................... 1 oz., or 25 grammes
- Distilled water............. 2½ fl. ozs., or 62½ C.c.
- Rectified spirit....... a sufficiency.

Dissolve the camphor in 10 fluid ounces (or 250 C.c.) of the spirit, and mix the solution with the liquid extract and water, adding sufficient rectified spirit to produce 30 fluid ounces (or 750 C.c.). Allow to stand for twenty-four hours in a cool place, and decant or filter from any deposit.

One hundred fluid parts contain 0.25 part of the alkaloids of belladonna.

* The third washing contains an appreciable amount of alkaloids; two experiments yielding me 1°5 and 2°0 Mgm. respectively.
Pulvis Extracti Belladonnae Compositus.

Take of—
- Liquid extract of belladonna ........................................... 4 fl. cts., or 100 C.c.
- Sugar of milk in powder ...................................................... a sufficiency.

Evaporate the liquid extract by the heat of a water bath until it is reduced to a soft extract; add now 2 ounces (or 50 grammes) of sugar of milk, and rub well together. Dry the resulting paste at a temperature not exceeding 212° F. (100° C.), reduce it to fine powder, and add sufficient sugar of milk to bring the whole to the weight of 3 ounces (or 75 grammes).

Note.—This preparation contains 1 per cent. of the alkaloids of belladonna, and corresponds in strength and dose to the green extract obtained from the fresh leaves. It should be kept in well-closed bottles.

Tinctura Belladonnae.

Take of—
- Liquid extract of belladonna ........................................... 1 fl. oz. or 30 C.c.
- Proof spirit ......................................................................... 29 fl. ozs. or 870 C.c.

Mix, allow to stand for twenty-four hours in a cool place, until filtered.

100 fluid parts contain 0·025 part of the alkaloids of belladonna.

Unguentum Belladonnae.

Take of—
- Liquid extract of belladonna ........................................... 1 fl. oz. or 30 C.c.
- Benzcoated lard .................................................................... 2½ ozs. or 45 grammes.

Evaporate the liquid extract on a water bath until it is reduced to a quarter of an ounce (or 5 grammes), add the benzcoated lard, and mix thoroughly.

One hundred parts contain approximately 0·3 part of the alkaloids of belladonna.

**EMPLEURUM SERRULATUM.**

BY JOHN C. UMBERY.

The leaves of *Empleurum serrulatum* occasionally appear in the port of London, either mixed with, or simultaneously with the shipments of *Barosoma serratifolia*. Unfortunately, when offered for sale by public auction, the drug is generally described in the brokers’ catalogues as Buchu. This practice has prevailed for twenty-five years or more, and reference is made to the leaves by Hanbury in ‘Pharmacographia’ (p. 99, edition 1874) in the following terms:

"The leaves of *Empleurum serrulatum*, Ait., a small shrub of the same order as *Barosoma*, and growing in the same localities, have been imported rather frequently of late and sold as Buchu. They have the same structure as regards mucilage, and nearly the same form as those of *B. serratifolia*, but are easily distinguished. They are still narrower and often longer than those of *B. serratifolia*, and terminate in an acute point without an oil duct; they have a bittersh taste and a different odour from Buchu. The flowers of *Empleurum* are still more distinct, for they are spatulate and reddish brown. The fruit, consisting of a single, compressed, oblong carpel, terminated by a flat sword-shaped horn, is quite unlike that of Buchu."

The fruit to which reference is there made differs from that of various species of *Barosoma*, which have five carpels covered with glandular dots, and the fruits, being almost always present in the bales of leaves, may afford excellent indication of the presence of *Empleurum* in the samples of leaves under examination. Holmes also has pointed out (Ph. J. [3], viii., 363) another distinguishing feature of the leaves, viz., that when the leaf of *Barosoma serratifolia* is held up to the light, the lateral veins are seen to be straighter, longer and more strongly developed than in the leaves of *Empleurum serrulatum*. The Hanbury Herbarium contains an excellent specimen of the dried plant, in which these important differences of both leaves and fruits may be readily observed.

Within the last two years, at occasional intervals, several bales of these leaves have been imported in excellent condition and unmixed with those of any species of *Barosoma*, and it was with a view of seeing what differences existed between these leaves and Buchu that the experiments of which the results are detailed below were carried out.

An interesting analysis is recorded* of the leaves of *Barosoma crenulata*, which was probably the first species imported, which agrees fairly well with the results obtained in an examination of the leaves of *B. betulina*, which has been carried out for comparison with the *Empleurum* leaves.

Water removed by successive boilings a considerable quantity of mucilage, which corresponds in behaviour with that derived from *Barosoma betulina*. It is not readily precipitated by alcohol, but affords a considerable precipitate with neutral acetate of lead.

The total amount of aqueous extractive dried at 100°C. was 43·4 per cent., or slightly in excess of that obtained from the *Barosoma* leaves, 36·2 per cent.

The aqueous infusion of the leaves possesses an odour resembling trimethylamine, possibly due to decomposition, and is so marked as to be distinctly noticeable in the freshly-distilled volatile oil, although it rapidly disappears on exposure to the air. It renders the taste of the infusion, moreover, so nauseous as to preclude the use of the drug, in the form of a fresh aqueous infusion at any rate, even though the therapeutic action be proved to be similar, as a substitute for Buchu. Ferric chloride has practically no effect on the cold infusion of *Empleurum* leaves, whilst with that prepared from *Barosoma betulina* a distinct greenish coloration is produced.

Alcohol extracts from the leaves, after the removal of fat and chlorophyll, 6·6 per cent. of a golden-yellow varnish-like body which, when treated with water, is only partially soluble. The insoluble portion had the characters of a soft resin, whilst the soluble part showed marked gluesidal reactions and was decidedly bitter. The leaves of *Barosoma betulina* yielded 6·91 per cent. of extractive to the same solvent, but differed in not containing any appreciable quantity of resin. After precipitation with neutral acetate of lead, the filtrate continued to show powerful reducing power with Fehling’s solution.

**Volatile Oil.**—The leaves possess a not unpleasant piperaceous odour, quite distinct, how-

* *Gmelin’s Chemistry,* ii., 1839.
ever, from that of buchu, and afforded on distillation 0·64 per cent. of a volatile oil, which was accompanied by the peculiar body having a fishy smell already referred to above.

After the disappearance of this on exposure to the air the oil possesses an odour recalling rue, though more pleasing, and has a specific gravity of 0·964 at 15° C. After keeping for some months, and even after cooling to -5° C, it showed no sign of separation of stearotep. It distils between 200° C. and 235° C., the greater portion passing over between 220°-230° C.

This fraction affords a crystalline compound with bisulphite of sodium, and may correspond with methylisouylketone, which is contained in oil of rue in considerable quantity, and may be separated from that oil by fractionation and treatment of the portion, distilling from 220°-228° C. with bisulphite of sodium; it does not, however, solidify on exposure to cold.

A quantity of the leaves of both B. betulina and B. serratifolia has been distilled for the purpose of comparison with the following results:

From B. betulina 1·4 per cent. of volatile oil was obtained, which deposited at ordinary temperatures a stearotenp amounting to about 30 per cent. of the whole oil, which after recrystallisation from alcohol melts at 82° C, and at a slightly lower temperature after resublimation, and agrees in general characters with diosphenol. The liquid portion of the oil after removal of the stearotenp boils at 205-210° C, and has a sp. gr. of 0·979 at 15° C.

Messrs. Schimmel record a larger percentage of volatile oil from B. betulina, viz., up to 2 per cent. the sp. gr. being 0·969 and yielding a considerable proportion of diosphenol.

B. serratifolia yielded 8 per cent. of volatile oil, from which no stearotenp could be separated by cooling, and having a sp. gr. of 0·9615 at 15° C.

The following table includes the principal

features of the oils of B. betulina, B. serratifolia, Ruta graveolens, and Empleurem serratiatum. The reaction of the oils with ferric chloride is confirmatory of the absence of diosphenol in the oils of both B. serratifolia and Empleurem serratiatum.

Special search was made in the Empleurem oil for salicylic acid, the presence of which in buchu oil was announced by Wayne,* but could not be found either in the oil of B. betulina by Maisch,† or in that of B. serratifolia by Bedford.‡ The suggestion of Professor Maisch that the presence of another kind of leaves, whether of the genus Baroena or some other genus, might account for the yield of salicylic acid may be therefore correct, but my observations point to the fact that such admixture was not, at any rate, the leaves of Empleurem serratiatum.

The proportions of extractive yielded to various solvents are tabulated below for comparison:

It is evident, therefore, that though the leaves of E. serratiatum show certain botanical and chemical affinities with buchu, their use as a substitute for that drug is not permissible without therapeutic examination.

**CUBERS AND ITS ADULTERATIONS.§**

(Concluded from page 758)

11. Piper syzygiyum, Lam.—The fruits in the Herbarium at Kew, which were examined, were gathered in Ceylon by Thwaites, and are cited as authentic by De Candolle. They are small, globular, mucronated, blackish, and scarcely reticulated, about 3·5 milli-

---

† 'Year-Book.' 1882, p. 196.
‡ 'Year-Book,' 1882, p. 196.
§ Abstract of paper by Dr. De Weyre.
12. *Piper.*—Dr. De Wevre has found in cubeb a another *Piper*, which at first he thought might be the young fruit of the *Piper cubeba* var. *crassipes*. He was, however, able to identify it with that of a plant in the Museum of the Society, received from Professor van Eeden, and which came from Java, bearing the native name “Kemokesean kêmêkê,” or “Dancêng Boesoeng.”

The fruit resembles that of *P. longum* in structure, having neither stone cells in the hypoderm nor in the endocarp, nor crystals of oxalate of calcium in the epidermal cells. The essential oil glands in the epicarp are, however, few, but large. The fruit is small, elliptical, elongated into a beak at the apex, and attenuated at the base into a short pedicel about 5 millimetre long.

*Fruits not derived from the Piperaceae, but met with in cubeb.*

---

**Fig. 10.—Endocarp and parenchyma of fruit of Daphniodium cubeba, transverse section.**

**Daphniodium cubeba.—** This fruit had been stated to be identical with that of *Tetranthera citrata* by Holmes, and Dr. De Wevre proved by a histological examination that the fruits of this false cubeb and of that of the *Tetranthera citrata* received from Java, and now in the Society’s Museum, are identical in structure. The endocarp consists of long, narrow, sclerenchymatous cells, crowded closely together in a single line, and arranged radially. The taste of the fruit is slightly bitter and aromatic, but not burning. It has usually no pedicel, and the pericarp contains a dicotyledonous seed without albumen, whereas in the cubeb the embryo is too small for the naked eye to distinguish the cotyledons, the mass of the seed consisting of albumen. The cells of the endocarp, have a very narrow linear cavity, and are very distinct from those of cubeb (Fig. 10).

*Rhamnus.*—The sample of adulterated cubeb containing fruits referred to *Rhamnus* was furnished by the Museum of the Pharmaceutical Society of Great Britain.

Dr. De Wevre has no hesitation in referring the adulteration to *Rhamnus*, although unable to identify the species. He gives the following characters:—

The fruits are rounded, but compressed laterally; on the lateral faces there are two rather deep furrows, separating the fruit into two, and on the other two sides a very slight median ridge.

Their colour is black, somewhat hidden by a whitish powder; the surface presents longitudinal ridges, which sometimes Anastomose by means of lateral ridges.

The odour resembles that of *Daphniodium cubeba*, mixed with the scent of a cigar box. The fruits have but little taste; after a time, however, a slight astringent favour is perceptible. In size they are nearly the same as cubebes. Sometimes a calyx with six teeth is observed at the base of the fruit. The fruit internally shows two cells, between which a columnella, due to the elongation of the pedicel, is visible. The pericarp contains resinous matter. The powdered fruits are distinguished under the microscope by the presence of a great number of stone cells of very different form to those of cubebes. They are narrower, often long, forked at the extremities, sometimes very irregular and mammillated. There are also bundles of long fibres, with pointed ends and thick walls. The cell-walls of the perisperm are coloured blue with loddine, which is never the case with cubebes. The same colouration takes place also with the fruits of *Embelia ribes*, which Dr. De Wevre suggests may some day be found in cubebes, as they have already been in black pepper. The fruits contain crystals of oxalate of calcium but no starch. Dr. De Wevre also gives details of the fruit of *Piper nigrum*, of which he remarks that there are two varieties, viz., *tritenum* and *macrostachyum*, and of allspice fruit, which M. Brunotte states that he has found in cubebes.

The conclusions at which Dr. De Wevre arrives as the result of his investigations are as follows:—

*Piper cubeba* is a variable plant, the principal forms being “Rinoe katemtofer,” “Rinoe badak,” “Rinoe tjaroloch,” and var. *crassipes*, De Wevre.

*Piper ribesoides* is properly an *Artanthe*. *Piper sumatrancum* is either identical with *P. ribesoides*, or is a variety of it.

*Piper crassipes*, Korth., is very near *P. ribesoides*, but requires further examination to determine its value as a species.

In *Piper nigrum* and in the *Piper* with a short pedicel (*P. schisonephros* or *P. baccatum*) the endocarp is only cutinised, not stony, and the hypodermal stone cells are very much developed.

In *Piper meilisium*, Bl., the endocarp is not sclerenchymatous, and the stone cells of the hypoderm are sparingly developed.

In *Piper oclusis*, D.C., and *P. guineense*, Schum., neither the endocarp nor the hypodermal present stone cells.

In *Piper longum*, Bl., and *P. sylinestre*, Lam., both

---

*Chemist and Druggist*, Nov., 1886, p. 620.
of Javanese origin, the structure is the same as in the
two preceding African species.

The name of *Piper canum* is applied to several
plants. The true *P. canum* is, in Dr. De Wervr's
opinion, the one at Kew, the fruit of which has short
pedicels and a structure resembling that of *P. olivrii*.

The pepper with short pedicels resembles *P. lovong*
in structure.

With respect to the detection of adulterations,
it is possible by the use of the microscope to detect
some of them, but in many cases there are not
sufficient characteristic features to serve for their
detection when mixed with the true cubah. In
some cases, as in *Piper cubeba*, var. *crassipes*, *P.*
*ribesicoides*, *P. crassipes*, Korth. *P. sumatraonum*, the
presence of numerous polygonal stone cells will indi-
cate adulteration, and the relative absence of stone
cells in *P. olivrii*, *P. lovong*, *P. canum* and *P. yl-
cestre* would indicate the presence of an adulterant.
The endocarpic cells of *Daphnadiun* are so distinct
that they would easily be seen if the powder were
first cleared with lignor potassae or *Eau de javaelle*, and
the colouring of the cell walls with iodine solution
would indicate the presence of *Embelia ribs* or *Rham-
us* fruits.

Dr. De Wervr, however, advises pharmacists to buy
their cubahs whole, and to examine the fruits before
powdering them.

THE RELATION BETWEEN CHEMICAL CONSTITU-
TION AND PHYSIOLOGICAL ACTION.*

BY T. BRYMER MARSHALL, D.Sc., EDIN.,
Professor of Chemistry, St. Mungo's College, Glasgow.

(Concluded from p. 607.)

ALDEHYDES.

We shall next consider the second group, where the
paraffins have undergone still further oxidation. Here
we have two hydroxyl residues replacing hydrogen
atoms, and we have produced a group of bodies called
aldehydes, which all possess the extremely active
residue CH(OH). This residue, however, is very
unstable, and under ordinary conditions splits off a
molecule of water (OH). The activity of living pro-
toplasm is most probably due to this aldehyde group,
and the readiness with which this residue condenses
or combines with other active bodies, polymereses or
becomes oxidised to acids or reduced to alcohols,
enables a number of complex changes to take place.
This extreme mobility explains the extraordinary
multiplicity of actions which take place in living pro-
toplasm.

Aldehydes are very powerful hypnotics, but cannot
be used owing to their powerful action on the tissues.
This powerful action is greatly modified when the
aldehydes are polymerised into closed chains—e.g.,
CH$_2$COH into para-aldehyde C$_8$H$_5$O$. The aldehyde
hypnotics do not depress the heart like the halogen
derivatives of the paraffins. We can greatly increase
the narcotic power by substituting halogenes in place of
the hydrogen in the aldehydes—e.g., chloral CCl$_3$
CH(OH)$_2$. Chlorine is best, because bromine and
iodine produce a too powerful depressing action on the

* From the Glasgow Medical Journal for January.
tives of ammonia, it will be necessary to refer to the unsaturated closed chain of 6 carbon atoms known as benzene \( \text{C}_6\text{H}_6 \), which is present as a nucleus in the so-called aromatic compounds. Hitherto we have only dealt with simple open chains. Benzene tends to produce increased sensibility, inco-ordination, and torpor, so that the effect of substituting a benzene radicle \( \text{C}_6\text{H}_6 \) in place of a hydrogen atom in ammonia, would be to modify the convulsive effect of ammonia. The action would therefore never assume that of true tetanus. To express the matter simply, we would say that the general physiological effect of a substituted ammonia containing a benzene nucleus is so to act on the grey matter of the cord, that stimuli do not reach the brain. This action is called analgesic action, which is the power of relieving pain.

By replacing another hydrogen of the ammonia, now containing a benzene ring, by acetyl, \( \text{CH}_3\text{CO} \), we further modify the tetanic action of ammonia, and produce the valuable antipyretic and analgesic, antifebrine, \( \text{C}_6\text{H}_5\text{NH-C}_2\text{H}_5\text{O} \). The still stronger analgesic, naloxine, \( \text{C}_6\text{H}_5\text{N(CH}_3\text{)C}_2\text{H}_5\text{O} \), is antifebrine with the remaining hydrogen replaced by methyl. Those substances which act as antipyretics are supposed to affect the temperature of the body by acting upon definite centres of the brain. The stimulation of these centres causes contraction of the protoplasm in the muscle and gland cells, thus lessening the oxidation process which is the source of heat.

\[
\begin{align*}
\text{NH}_3, & \quad \text{C}_6\text{H}_5\text{NH}_2, \\

\text{Aniline.} & \quad \text{Antifebrine.} \\
\text{C}_6\text{H}_5\text{N(CH}_3\text{)C}_2\text{H}_5\text{O.} & \quad \text{Naloxine.} \\
\text{Antipyrine.} & \\
\text{ANTISEPTIC.} &
\end{align*}
\]

In the earlier part of the paper I referred to the anesthetic properties of the halogen derivatives of the paraffins, but did not mention the antiseptic action which the halogens convey to the hydrocarbons. It is found that all highly halogenated derivatives of the hydrocarbons are powerful antiseptics, but are dangerous owing to their anesthetic action; still, they are useful where this latter property is desired. The derivatives of benzene and other closed chains are more powerful and less poisonous than the above; and there are a large number of benzene derivatives containing iodine, which are superior to iodine (which is the most powerful of the paraffin series), as they are devoid of smell, and probably produce no poisonous effects.

In considering the employment of antiseptics for internal disinfection, we must be very careful to study the effect they may produce on the organism. It is found that the diphenyl (diphenyl, \( \text{C}_6\text{H}_4 - \text{C}_6\text{H}_4 \)) are less poisonous and more powerfully antiseptic than the benzene (benzene, \( \text{C}_6\text{H}_6 \)) derivatives. It is, however, interesting to note that the poisonous action of benzene can be greatly reduced by sulphonating. For instance, the poisonous carbolic acid, \( \text{C}_6\text{H}_4\text{OH} \), which possesses powerful antiseptic and slight anesthetic properties, is converted into the comparatively safe antiseptic substance, \( \text{ascopol} \), \( \text{C}_6\text{H}_4\text{OH-SO}_2\text{H} \), by introducing the sulphonic acid radicle - \( \text{SO}_2\text{H} \). Probably the safest and most potent antiseptic will be found amongst the diphenyl sulphonic acid derivatives.

**The Effect of Hydroxy1 in Benzene.**

Benzene, although active to a slight degree itself, is converted into a powerful poison and antipyretic by the introduction of the hydroxy1 group, which again proves the great activity of this radicle. This toxic action is increased with the increased number of hydroxy1 groups.

**The Pyridine Class of Bodies.**

Pyridine, \( \text{C}_5\text{H}_4\text{N} \), may be looked upon as benzene with one of the carbon atoms replaced by nitrogen. This pyridine nucleus is interesting from a physiological point of view, as it is to be found present in nearly all the alkaloids, and there is no doubt that this group characterises the physiological action of these complicated bodies. Dr. Stockman has found that all the pyridine derivatives have an antiseptic and antipyretic action. In studying the physiological action of pyridine and its derivatives, he found that the action was diminished by substituting alkyl groups in place of the hydrogen atoms; also, that by saturating the ring by addition of hydrogen they are rendered nearly harmless.

By saturating the nitrogen by the addition of methyl iodide, the physiological action is so modified that a curare action is produced (the property of paralysing the motor nerves). It is, however, well to remember that, in all these cases of substitution and addition to a nucleus, the change in physiological action is not sudden or profound, but that this action is simply modified in particular directions, although the symptoms produced may be in themselves profound.

**Cultivation of Ginger in Jamaica.**

The Director of the Public Gardens and Plantations in Jamaica has recently drawn up, at the request of the Governor, a report on the ginger crops in the island. It is well known that Jamaica is noted for its ginger, the produce of the island being the finest quality known in the market, and consequently it realises the highest price. Mr. Fawcett's notes on the subject will, therefore, interest those engaged in its culture, not only in Jamaica but in other ginger-growing countries. He remarks that the quality of commercial ginger is due chiefly to soil, but also to curing, to the variety, white or blue, and to whether it has been freshly planted a few months before, or has been "ratooning" for one or more years. The soil which produces the very highest quality, realising perhaps £10 per cwt. in the London market, is the very deep black soil of the virgin forest. To grow ginger under this condition involves the destruction of large areas of forest.

Magnificent trees, six feet in diameter, may be seen in some districts lying rotting on the ground, while the ginger cultivators have gone further to the centre of the island, abandoning the woodlands already cut down. The plan adopted in clearing the forest is for a cultivator to invite two or three of his friends to a "cutting match"; he provides food and drink, and the laborious work of felling trees is carried on merrily and without much expense. Afterwards fire is applied and the place is burnt over. This burning is considered
very important, as much so as the virgin soil. Probably its importance is due principally to the deposit of potash and other mineral matters contained in the ashes, but the fire also sweetens the ground, correcting sourness, and, moreover, it destroys insect pests. Some cultivators will grow ginger only in freshly-cleared woodlands, and next year they move on to a new clearing, but although they get in this way very fine ginger, it is at the expense of forest land, which would require a very heavy outlay and, perhaps, a term of a hundred years to restore. Albert Town was, not so long ago, a centre for the cultivation, but it seems that growers have already got as far as fourteen miles further inland. Ginger can be, and is, grown in many places, year after year, on the same ground, even for forty years in succession. At Seaford Town, a German colony, one of the original colonists, an old man of eighty-six years, is said to have been cultivating ginger and arrowroot in the same place from his youth, he and other colonists have been in the habit of planting a small patch one year, leaving it to “ratson,” as long as it was profitable, then throwing it up or growing other plants, until, after a term of years, they again plant the same patch with ginger. This is an irregular rotation of crops. “Plant ginger,” the produce of planting, is of better quality than the ratsons, and the ratsons in each succeeding year are inferior. When the ground is too poor to grow white ginger, then the inferior blue variety can be grown. More depends upon the curing of ginger, considering the crop as a livelihood, than soil. At Seaford Town there was a wet season about two years ago; the people could not dry the ginger in the sun; it mildewed; there was very little sun, and the cultivators suffered some distress. Careful attention to the curing is quite the rule, and badly-cured ginger, that is sometimes brought to the market, is due to wet weather, rather than to want of care.

Though it is difficult to make any recommendations on the subject, the following hints are given, as indicating what points are worthy of consideration by cultivators:—The first is the application of manure. There is a prejudice against its use, some maintaining that it breeds worms, and that there is also a difficulty in getting it in any quantity. It is probable that those who have not succeeded with manure have used it improperly, by applying it fresh, or not sufficiently mixed with soil. As to obtaining it in quantity, example should be taken from the Chinese labourer, who preserves every particle of matter that can in any way be utilised as manure, not only cattle manure, but decaying matter of any kind, night soil, etc.; even soapy water, left after washing, is most useful. To imitate the formation of forest soil, a pit might be filled with alternate layers of bush and manure; everything in the nature of manure or decaying matter should be thrown in, and a layer of soil directly over the manure would be useful. The pit ought to be lined with clay, to prevent the very valuable part of the liquid of the manure from escaping, and a cover of some kind should be fixed in some way over the pit, to keep out rain.—Journ. Soc. Arts.

**GLYCERIN OF THE MARKET.***

**BY J. L. TEGARDEN, PH. O.**

In order that the sources of impurities and adulterations that are liable to be present in glycerin may be understood, a brief review of the process of manufacture is necessary.

Commercially, glycerin is invariably obtained as the result of the decomposition of neutral fatty bodies in the process of manufacturing either candles or soap. Long experience has shown that fatty oils from all sources yield not isomers and homologues of glycerin, but exactly the same variety of glycerol. Various agents have been employed in the saponification of fats. In former times olive oil was boiled with oxide of lead and water; later the liqbus was replaced by lime; succeeding these processes saponification was effected by water and high pressure, by sulphuric acid, by superheated steam and subsequent distillation.

At present by far the greatest amount of commercial glycerin is either a by-product of the soap manufacture, and is made by saponifying with caustic soda, or is the result of the saponification of fats with some base, under high pressure. The “sweet water,” as it is called, which is formed, is separated at this point by pressure or distillation, and then concentrated or distilled. In leading manufactories of England and America, zinc oxide is now used to replace one half of the lime. It is claimed that the reducing action of the zinc prevents the discoloration of the fatty acids resulting from other treatment. It will be seen, then, that impurities do not naturally exist in glycerin, but are introduced by the re-agents used in its manufacture.

Neither the colour nor the specific gravity of a sample are safe indications as to whether it consists of crude or distilled glycerin. As a rule, the latter is light in colour, but may be brown and even black, and its specific gravity rarely exceeds 1.261; whereas, the former is usually dark, varying in colour from yellow to black, and ranging in specific gravity from 1.25 to even less to as high as 1.37, according to the degree of concentration. One of my samples which subsequently proved to be a chemically pure article gave a specific gravity of 1.268, while the one containing the most impurities gave a gravity of 1.229. A good indication as to the quality of glycerin can be obtained by subjecting it to ignition, as the amount of mineral residue in distilled glycerin is never more than 0.2 per cent, whereas all crude samples contain much more—soap-like glycerin containing as high as 9 to 14 per cent.

The U.S.P. ignition test is to place a small portion of the glycerin in an open evaporating dish, then heat gently till it ignites. It should burn and vaporise, and not leave more than a dark stain. This establishes the fact of the absence of dextrin and sugar. And then, on full combustion, no residue whatever should be left; this indicates the absence of fixed impurities. Out of the thirteen samples tested, all were free from sugars and fixed impurities except numbers eight and ten. No. 8 contained a sufficient amount of ash to be considered a crude sample. Sullivan and Berry, who are acknowledged by A.H. Allen to be authorities

*Read at the Asheville meeting of the American Pharmaceutical Association.*
on this subject, say that a preliminary distinction between a crude and distilled product is indicated by the former causing a great deal of spluttering during volatilisation, while the latter volatilises quietly. In this respect, also, the above suspected sample indicated a very poor quality of a raw or crude glycerin. By a more thorough analysis this sample was found to contain as intentional impurities magnesium sulphate and glucose, these being used extensively in some manufactories for the purpose of adulteration.

Fehling's method is recommended as the best test for the detection of sugars. It is impossible for this substance to occur in glycerin unless employed as an adulterant, and consequently it is only necessary to look for it in a distilled product. The Pharmacopoeia directs that 5 C.c. of glycerin be mixed with 50 C.c. of water and 10 drops of hydrochloric acid in a small flask and heated for thirty minutes on a water bath; and then mix 10 C.c. of the liquid with 2 C.c. of sodium hydroxide T.S. (= test solution, U.S.P.), and 1 C.c. of alkaline cupric tartrate T.S. No yellowish-red cloudiness should appear within six hours. Some of the samples analysed by this method were found to contain sugar.

To detect the presence of formic and butyric acids, gradually heat 5 C.c. of glycerin with 3 C.c. of dilute sulphuric acid below the boiling point. There should be no offensive or acidulous odour evolved. Six of the samples gave reactions for the above-named acids. As has been stated, the variety of impurities that are found in commercial glycerin are such as are contained in the re-agents used in the manufacture of it. Sulphates and sulphur compounds, chlorides, lead, iron, zinc, calcium, magnesium, arsenic and other metals, oxalic acid, resinous matters and fatty acids are the impurities that are likely to be detected in glycerin. Sulphates always occur where sulphuric acid has been used as the saponifying agent of the fat. Sulphites, sulphides, and thiosulphates are also formed. Calcium is also met with in the form of an olate. Oxalic acid sometimes occurs in glycerin, being used either as a re-agent or an oxidation product. Three of the samples contained sulphates, five contained calcium salts, none contained oxalic acid, and all were more or less contaminated with chlorine in the form of either a sodium or a calcium salt. The Pharmacopoeia says: "No colour, cloudiness or precipitate should appear when separate portions of its aqueous solution (1 in 10) are treated with hydrogen sulphide or ammonium sulphide T.S. (absence of metals), barium chloride T.S. (absence of sulphuric acid), calcium chloride T.S. (absence of oxalic acid), or ammonium oxalate T.S. (absence of calcium salts)." The tests for chlorides are based upon the readiness with which silver chloride is formed when glycerin containing a chlorine is brought into contact with silver nitrate in diffused daylight. Acrolein is an irritating aldehyde which should not naturally be developed in a good sample of glycerin. Professor Coblenz, of the College of Pharmacy of the City of New York, says that if there be the least trace of acrolein in glycerin, it can always be detected by adding 1 C.c. of fuchsin (decolourised by sulphur dioxide), and if present the mixture will assume a purple colour. By this method a trace of acrolein was found in each of the samples I analysed.

For the past few years it has been repeatedly stated that some samples of glycerin intended for pharmaceutical and medicinal purposes contained a sufficient quantity of arsenic to cause suspicion and alarm. That this fact was known to the manufacturer there is no doubt, but it is also true that he took great care not to enlighten the consumer on this most vital and important point. The arsenic in glycerin, like most other accidental impurities named in this article, has its origin in the re-agents used in the manufacture. It has been stated by good authority that distilled glycerin would not be contaminated with arsenic. A. H. Allen, in discussing the subject in the British Pharmaceutical Conference, at Leeds, in 1892, seemed to entertain some doubts about it, yet in his concluding remarks he distinctly states that it can be removed by distillation. Mr. Lewkowitsch, in a recent article on glycerin, takes a different view of the subject. He says that arsenic exists in glycerin in the form of an arsenious ether of glycerin, A12O3(C2H5)2. From experiments conducted by him, he finds that arsenic in this form distils over at 250° C., the same temperature at which glycerin is distilled. If this be true, there is no practical process by which glycerin, once contaminated with arsenic, can be completely freed from it. Therefore, chemically pure glycerin, free from arsenic, is produced only when re-agents not containing it are employed.

With a view to ascertain what proportion of commercial glycerin was free from this poisonous drug, I examined all the samples I had, which were mostly of different manufacture. Seven of the samples contained comparatively large amounts. Two samples contained minute traces, which might be disregarded, while four were absolutely free from it. The method used for detecting arsenic was that introduced by Gutzeit, and now recognised by the Pharmacopoeia. It consists in allowing the gas slowly eliminated by the action of sulphuric acid on zinc in presence of the liquid supposed to contain arsenic, to come in contact with three thicknesses of filter paper moistened with a saturated acid solution of silver nitrate. In order that sulphides which might be formed may not reach the filter paper, a plug of cotton or glass wool, moistened with lead acetate solution, is introduced into the mouth of the test tube. The presence of arsenic is shown by the production upon the paper cap of a bright yellow stain, which turns dark by the application of water. Vulpins, Flickiger, and Siebold employ a modification of this test. Vulpins and Flickiger substitute hydrochloric acid for sulphuric acid, and do not use the moistened plug of cotton. Siebold modifies the method just described by using instead of silver nitrate a solution of mercuric chloride. In the latter test a yellow spot will be the result of minute traces of arsenic.

To recapitulate, glycerin intended for medicinal purposes should be distilled once or twice. It should have a specific gravity of at least 1:25, and should be free from all metallic and organic impurities and adulterations.
it leads to more accurate results. The view put forward by Professor Cash is precisely what might be expected from a pharmacologist, and in that respect it is entitled to consideration. But it covers only part of the ground that must be surveyed in deciding what changes are to be made in the national Pharmacopoeia to meet the requirements of medical practice. The arguments brought forward on the ground of empirical experience, in favour of the retention of remedies and preparations which do not admit of a scientific explanation of their efficacy, cannot be ignored without producing a feeling of antagonism on the part of a large portion of the medical profession.

The paper read at the Liverpool Chemists’ Association by Dr. Carter, and published in last week’s Journal, will serve as an apt illustration of the fact that therapeutic experience and pharmacological observations are not unfrequently at variance. However much some medical men may be inclined to agree with a strictly pharmacological view of the therapeutio use of remedies, there are many others who hold very different opinions and follow a very different practice. How much is known concerning the chemical constitution of cinchona bark, and why are better results obtained by its use than by the exhibition of definite chemical principles extracted from it? The effect, however, of such a rule as that suggested by Professor Cash would be to remove cinchona bark and its preparations from the official list of medicines, whilst leaving quinine, cinchonidine, etc., to serve the same purpose, more or less effectively. Dr. Cash fortunately does not propose the adoption of any such rule, and the position he takes up generally is worthy of commendation. It is impossible to exercise too great care in deciding as to the fitness of a new remedy to become recognised officially, and, as Dr. Cash points out, other considerations than the main one present themselves before novelties are admitted into the Pharmacopoeia. Thus, it should be shown that there is a distinct necessity for their inclusion, that they are more effective than similar remedies already official, or that they are articles supplying a place not yet occupied.

SYNTHETIC FOOD.

In his retiring address as President of the American Chemical Society, Mr. H. W. Wiley considers the possibility of preparing human nutrient synthetically. After summarising the progress that has been made in the synthesis of organic compounds, he proceeds to criticise Berthelot’s utterances regarding the coming suppression of agriculture and the substitution of synthetic foods for its products. Berthelot is said to hold that, even at the present time, tea and coffee could be made artificially if the necessity should arise, his arguments being based on the facts that
theine or caffeine is obtainable from theobromine, theobromine from xanthin, xanthin from uric acid, uric acid from urea, urea from carbonyl chloride and ammonium, carbonyl chloride from carbon dioxide and chlorine, and carbon dioxide from carbon and oxygen. In like manner he holds that tobacco may shortly be made because something resembling nicotine has already been made synthetically. According to BERTHELOT, the fields which are now defaced by agriculture will be beautified by regaining their natural covering; the earth will be one vast park of pleasure and the chemist the great conservator of the human race.

In all the instances brought forward, however, it is pointed out that there is not the slightest approach to anything to justify the prophecy of a period of artificial food. The few cases of synthesis in which the products approach the composition of anything digestible are said to present such insurmountable difficulties in expense and supervision as to render any expectation of reaching economic results apparently futile. In the great majority of cases, too, the process of synthesis is conducted on materials already organised by living cells, and the enormous cost of building up any kind of a commercial, synthetic body directly from the elements is such as to render its successful achievement, in Mr. WILKIE's opinion, utterly improbable.

Finally, it is remarked that, even if food products could be formed in the crucible, Nature's laboratories are infinitely cheaper in construction and operation than those filled with platinum and porcelain. The sun ignites the crucibles of Nature at far less expense than attends the use of gasworks, whilst the director of Nature's laboratory depends on no endowment nor legislation for his salary, and his bills for supplies are not disallowed by any board of auditors on the score of economy. "Night and day his patient faithful assistants work without thirst for fame, without hope of reward. They fight not for priority of discovery, and their anonymous papers are printed in rich profusion in the great Berichte of the universe. The chemistry of the chlorophyll cell is far more wonderful than any of the achievements of Lavoisier, Berzelius, or Fischer."

STRENGTH OF COCAINE SOLUTIONS.

Amongst the preparations which require careful consideration in the revision of the Pharmacopoeia cocaine stands prominent. Five years ago it was not unusual in this country to meet with prescriptions for solutions of 10 per cent. strength to be used hypodermically. At the present time it not rarely happens that 5 per cent. solutions are required for this purpose. Yet we find much weaker solutions in common use, and a 2 per cent. solution is now most frequently asked for. On the Continent hypodermic injections of 1 per cent. are employed. Thus, a French surgeon, A. RICARD, writing in the Gazette des Hopitaux, February, 1895, recommends a solution of this strength for injecting into the tissues to produce local anesthesia in operations on the anus. SCHLICH has found that in the skin 0.2 per cent. solution of cocaine produces anesthesia without causing pain immediately after the injection. This solution is thus 100 times weaker than that most commonly employed in this country. This drug is of such common use that it is of importance to have a formula which will allow of its being kept ready for use in solution without fear of deterioration. Boric acid is usually employed for this purpose, but it probably makes the first injection more painful than it would otherwise be. SCHLICH's formula is:

- Cocaine hydrochloride ........ gr. h.f.
- Morphine hydrochloride .......... gr. 2
- Soda chlor. ......................... gr. iii.
- Ag. dest. ad. ........................ $ii.
- Ac. carbol. (5 per cent.) .......... mili

This is for use on painful areas; for operations on healthy parts the cocaine is reduced to gr. 1/2. It is to be hoped that standard solutions will be fixed by the revising committee.

ANNUAL DINNER.

At a meeting held at 17, Bloomsbury Square, W.C., on Wednesday last, the President, Mr. MICHAEL CARTMIDGE, in the chair, it was decided to hold the annual dinner of the members of the Pharmaceutical Society and their friends at the Whitehall Rooms, Hôtel Métropol, on Tuesday, May 21 next, at 6.45 p.m. for 7 p.m. The President, Vice-President, Professor ATTFIELD, Dr. PAUL, and Messrs. ALLEN, BourDAS, BUTT, FRAVER, CLARKE, HILLS, HOPKIN, R. A. ROBINSON, TAYLOR, and WARREN will form the Committee, and Mr. RICHARD BREMMIDGE, 17, Bloomsbury Square, was appointed to sit as an Honorary Secretary. The tickets (one guineas each) will be obtained only from the Secretary, and it is desired that gentlemen willing to act as stewards will notify him to that effect as early as possible.

EVENING MEETING IN EDINBURGH.

An evening meeting of the Pharmaceutical Society will be held at 36, York Place, Edinburgh, on Friday, March 23, at 8.30, when the chair will be taken by Mr. J. LAIDLAW EVANS, Chairman of the Executive of the North British Branch, and the following paper will be read:—"Decomposition of Alcohol-Reduced Chloroform," by D. BROWN, and D. R. BROWN. A discussion on the proposed "imperial" pharmacopoeia will take place subsequently; "Ointments" being dealt with by P. BOA; "Infusions," by W. LYON; "Pills," by J. I. FRASER; "Extracts," by W. SWAN; "Waters," by W. S. GLASS; "Linseed Meal," by A. J. DAY, and "Recent Criticisms," by T. MARSH, whilst "General Notes" will be contributed by J. R. STEWART and G. COULL. Recent additions to the museum will be exhibited by the Assistant-Secretary, Mr. J. RUTHERFORD HILL.
EVENING MEETING IN LONDON.

The fourth Evening Meeting of the Session was held on Wednesday, the 13th Inst., at 8 o'clock, Mr. Michael Carteige (President) in the chair.

The first paper read was on "Standardised Preparations of Belladonna," by Mr. R. A. Cripps, F.I.C. It is printed at p. 783, and gave rise to the following discussion.

Mr. Martindale said he could not quite agree with the line Mr. Cripps had taken, in producing a preparation which represented two parts by weight of the root in one part of the fluid extract. That seemed to be going in the direction of pharmacy made easy, which he did not agree with, as it would lead to retailers simply obtaining from wholesale houses one article from which to make all their preparations. That sort of thing was done to a great extent in America, and tincture of nux vomica became little more than a solution of strychnine. The pharmacocepal tincture of 1 in 20 was absurdly weak; a tincture of a plant should represent conveniently a spirit solution which should reasonably extract the drug without waste of material, and the present weak tincture would probably give way to something stronger, or to a fluid extract, though he doubted whether it would be such a fluid extract as Mr. Cripps suggested. At Chicago there was a debate on normal percentage fluid extracts, and it was then generally agreed that 1 in 1 was too strong, and that a 1 in 2 preparation would be much more suitable for general purposes, but then it was suggested that the manufacturers would put an article on the market double the strength and beat the ordinary pharmacist. It was doubtful whether in many cases a 1 in 2 preparation could be made which would represent the whole activity of the drug. Mr Groves told him that a preparation ought to, as far as possible, exhaust the drug, but he would not say it was possible for it to equal the whole medicinal activity. It was not necessary to completely exhaust the drug, and in many cases it would be waste of time and material to attempt it. A 2 in 1 preparation he should imagine would be too concentrated to contain the whole medicinal activity. From a great many experiments made during the last year he found the total alkaloids contained in belladonna leaves averaged 5 per cent., which pretty well agreed with Mr. Cripps' results from the root. One advantage in using the leaves was that you did not kill the goose which laid the golden eggs, as you did in digging up the root; on the other hand, there were many advantages in using the root especially for liniment and plaster, though it lacked the green colour which some liked, but which he did not. He thought there was on the average about 3 per cent. alkaloid in extract made from the root, and about 2 per cent. or a little under in that made from the leaves.

Mr. G. Umnny said Mr. Cripps had done good service in collecting the results of so many experiments on belladonna. Much as he should like to see a 4 per cent. solid extract of the root, he did not think it would be possible to obtain it in practice,
except occasionally, and therefore the solid extract should be fixed at 5 per cent. The average of his work on large quantities was about 3-2. In the fluid extract a convenient standard would be 1 per cent., though he should have liked to see the solid extract double the strength of the fluid, as a matter of symmetry. With regard to making the tincture from the root instead of the leaves in future, it was necessary to proceed with caution, as medical men were accustomed to prescribe pills made from the green extract, and with doses of about double what would be ordered of the alcoholic extract. With regard to English and foreign roots, he had lately worked on about four tons of English roots, and the percentage of alkaloid was rather better than foreign roots, but he was not prepared to say that if the latter were more carefully collected they would not be of equal value; they generally had pieces of stem attached, which of course lowered the percentage. He had on examination shown how nearly English roots agreed: one sample from Brighton gave 44 of alkaloid; one grown by Mr. Holmes 48; some grown in Germany only gave 30. But there was no reason why roots grown in Southern Europe, and large quantities were shipped from Trieste, should not be as good as English. He did not like using sugar of milk as a diluent in such a case as this, as with a powdered extract of this potency you were dealing with a very sharp edged tool.

Mr. Gerrard said the present belladonna plaster was a very unsatisfactory preparation; it made with real alcoholic extract, as it was intended to be, and of the strength given, and applied to a person's back, the consequences would be serious. The plaster generally made now was prepared probably from a proof spirit extract, and he hoped this point would be attended to in the new pharmaepoia. When the alcoholic extract was made with alcohol of say 84 per cent., it separated after a day or two into two portions, and on that ground alone was unsatisfactory, though he did not know whether the upper or lower portion was most active, though he thought it probable the upper portion was more inert, and consisted largely of chlorophyll substances; there was always a little of this in alcoholic extract of the root which could be extracted by washing with ether. Another preparation largely used was glycerin of belladonna, which he had had to prepare by the half hundredweight; it was always made with the green extract, and he considered it unsatisfactory; it was applied in such large quantities that he could not but think it must be very weak, and it was very uncleanly. He was glad to hear that Mr. Crieff recommended the titration method for the alkaloidal residue, in addition to weighing.

Mr. J. C. Umney said his attention had recently been called to the separation of the alcoholic extract made with 84 per cent. spirit into two portions. On examining it, he found that the more liquid part contained 7-7 per cent. of total alkaloids, instead of between 3 and 3-25, which was the figure for the whole extract mixed together. Thinking he must have made a mistake, he repeated the experiment, and found 7-8, so that there was no doubt about this separa-

ration making a great difference in the potency. With regard to the peculiar effect sometimes produced by belladonna, he held it was due to an idiosyncrasy of the patient rather than to any difference in the strength, owing to its being made from the root rather than the leaves, because he had recently to examine a plaster which had produced blistering, and it was made from leaves and contained only 1-8 per cent. total alkaloids.

Mr. J. C. Umney said he had often had complaints about belladonna plaster producing blistering, and he had formerly been under the impression that it was in consequence of the plaster being made from the root, but the instance just mentioned by his son convinced him that it was not so.

Mr. Gerrard said it was well known that atropine preparations, when applied to the skin, would produce what was called "belladonna rash," and he believed the effect referred to was due mainly to the atropine.

Professor Attfield said he was there to learn rather than to contribute anything to the subject of the standardisation of drugs, and he must say he had learned a good deal both from the paper and the discussion. There could be no doubt that the next pharmacopoeia would have to include a large number of standardised alkaloidal preparations. They could not go on using tinctures, extracts, fluid extracts, and various preparations containing highly variable proportions of mixed alkaloids. Then came the question what should be standardised, and what methods should be adopted. There was also the objection of men who said they did not believe much in preparations which contained such a number of constituents, and they preferred to use the pure alkaloids. Such men, of course, must prescribe accordingly, but the vast majority of practitioners used galenical preparations, and their interests must be met by standardisation where possible. They could not hope to have a perfect method of doing so; it was obviously impossible to do with many of these things as with arsenic or mercury, i.e. make a definite percentage solution, because they were not dealing with definite substances. All they could do was to fix their minds on a particular alkaloid known to be the chief active principle, ascertain how much was present in the raw material, and decide how much should be in the preparation, and then find out the best way to ascertain the proportion of that alkaloid in a given galenical substance. If they could not do that they must be content to deal with the total alkaloids. It was not because they had not as yet perfect knowledge that they were to do nothing. Then came the question, How much should be attempted? They must improve on what had been done for cinchona, opium, and nux vomica, and he did not see why they should not have standardised preparations of hemlock, henbane, stramonium, jalap, belladonna, and ipecacuanha. He did not think they were as yet in a position to includeaconite, but there were about ten, and there might be some others which might be standardised.

Mr. Crieff, in reply, said he did not think Mr. Mardinal's objection to "pharmacy made easy" would apply. A very large number of pharmacists would be very
glad to standardise preparations of belladonna, nux vomica, and so on, but it was impossible to do so when they only made small quantities; but if they could buy or make one preparation, like the liquid extract, from which they could prepare all the others, they could standardise that for themselves, and this would operate against buying things in a slipshod way. As to the strength of 2 in 1, he had made it without differing from an average strength root, but he could not yet speak as to its keeping properties. He would admit that there were many drugs in which a 1 in 1 fluid extract would be an impossibility, and in some cases 1 in 2, but in the case of belladonna it was quite easy. This preparation contained about 90 per cent. of the alkaloids in the drug, which was quite strong enough, and the remainder could easily be recovered working on a large scale. As to the waste of material, it was as long as it was broad; if you had 10 grains of alkaloid in a given quantity of drug, it did not matter whether you made a gallon of tincture or an ounce of extract, the absorption of spirit by the given weight of drug would be the same, and the actual loss of spirit was very small. As to foreign roots, he thought Mr. Umney must have had a bad parcel, as had happened to himself, both with foreign and English. He had examined a good many foreign samples, and found over 7 per cent. After what had been said as to the difference in strength of the two portions of the alcoholic extract, it was a serious question whether such an article should be allowed to remain in the Pharmacopoeia. He had heard a good deal from time to time about the blistering effects of belladonna plaster, and agreed that it was due to idiosyncrasy; he had once examined a plaster which produced this effect, and found it rather weaker than usual. He had tried washing with ether, as Mr. Gerrard suggested, and found that it removed a good deal of the alkaloid.

The President, in moving a vote of thanks to Mr. Cripps, remarked on the great increase in the demand for preparations of belladonna since the use of the root had been introduced. He thought there could be no doubt that the introduction of standardised preparations was to the advantage of pharmacists from a business point of view.

The next paper was on "Empyreum serrulatum," by Mr. J. C. Umney. This is printed at p. 798, and gave rise to the following discussion:

Mr. Holmes said his attention was called some time ago to an oil of buchu which contained diosphenol to the extent of 50 to 40 per cent., and thinking it would be interesting to know whether this substance had any medicinal properties, he sent some to Dr. Cash, who reported that on trying it in cases of vesical catarrh it had the same effect as buchu itself. It appeared, therefore, that those leaves which contained this substance should be used in preference to those which did not.

Professor Attfield asked if Mr. Umney would recommend as the result of his investigations that B. serratifolia should be excluded from official recognition, and the other two retained, or as Mr. Holmes hinted, that only one variety should be recognised.

Mr. Martindale said he always preferred the B. serratifolia, as it contained more mucilage.

Mr. Holmes said, according to his experience, the B. betulina was most frequently met with in commerce. Whether B. crenulata contained diosphenol he could not say.

Mr. C. Umney said he well remembered Mr. Daniel Hanbury having a large quantity of the essential oil made, which he examined, and he believed it was from that sample the experiments were made which were described in the 'Pharmacographia.' The B. serratifolia only came into the market occasionally, as a rule, but just now the market was flooded with it. The crenulata, or betulina, was mostly sold. The price varied from 6d. to 2s. a lb.

Mr. J. C. Umney said he did not know until that moment of the result of Dr. Cash's experiments, but there was no doubt there was a difference between the B. betulina and serratifolia, the latter yielding no diosphenol whatever, while the former gave 30 to 40 per cent.

Mr. C. Umney said he believed the lance-leaved variety was richer in mucilage, and was valued on that account.

The President proposed a vote of thanks to Mr. Umney, which was carried unanimously.

Mr. Durholdt then exhibited an automatic still, which is described on p. 99 of this week's Eptome. Reynolds and Branson's "Bandage-shoot" and "Pill-box-shoot" were also shown.

Proceedings of Societies in London.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 16, Bloomsbury Square, on Wednesday, March 6.

Present:—Mr. N. H. Martin (President), Messrs. Cartelghke, Hayes, and Umney (Vice-Presidents), Mr. Moss (Treasurer), Mr. Bird, Messrs. Naylor and Ransom (Hon. Gen. Secs.), and Mr. Nightingale (Asst. Sec.).

Letters were read from Messrs. Atkin, Martindale, Reynolds, Ewing, Wells, Farr, and Holmes, regretting their inability to be present.

The minutes of the previous meeting were read and confirmed.

Reference was made to the death of Professor Flückiger, and on the motion of the President, seconded by Mr. Cartelghke, a resolution was unanimously passed expressing the regret that the Committee felt at losing so distinguished a honorary member of the Conference, and the Secretaries were requested to forward a copy of the same to Frau Flückiger, expressing sympathy with her in her bereavement.

From a statement received from the Treasurer, it appeared that the subscriptions indicated some falling off in membership, and considerable discussion ensued as to the best means to be adopted to obtain an increase in the number of members, and to improve the financial condition of the Conference. It was finally
decided that a special circular should be drawn up by the President and Hon. Secs. and addressed to the members of the Conference, urging upon them the necessity of individual effort to obtain candidates for election.

By a unanimous vote, Mr. Louis Slabold, F.I.C., F.C.S., was re-elected editor of the 'Year Book.'

The Treasurer and Hon. Secretaries were requested to revise the 'Blue List' and make any alterations that they deemed necessary.

Eight gentlemen, having been duly nominated, were elected to membership.

CHEMICAL SOCIETY.

A meeting was held on Thursday, March 7, the President, Dr. Armstrong, F.R.S., in the chair, the following papers were read:

DIMETHYL-KETO-HEXA-METHYLENE.

BY DR. KIPPING.

The author has previously shown* that the higher fatty acids of the C_{n}H_{m}O_{2} series can be readily transformed into ketones by the action of phosphoric anhydride, the reaction taking place according to the following equation:

\[
\begin{align*}
\text{R} + \text{R} & \quad \text{COOH} + \text{COOH} \\
\text{COOH} & \quad \text{CO} + \text{CO} + \text{H}_{2} \text{O}
\end{align*}
\]

If, however, a dibasic acid were used a ketone of a methylene derivative would be obtained:

\[
\text{CH}_{2} \text{COOH} + \text{CH}_{2} \text{COOH} = \text{CH}_{2} \text{COO} + \text{CO} + \text{H}_{2} \text{O}
\]

Experiments were made with dimethylpimelic acid with the hope of obtaining the corresponding ketone, which would be a dimethyl-keto-hexa-methylenic. The acid, however, did not react with phosphoric anhydride in this way, so resource was had to other methods in the hope of obtaining this ketone.

It had been shown that when calcium salts of the higher dibasic acids of general formula C_{n}H_{m}O_{2} were distilled, similar ketones were obtained. By distilling calcium suberate, a keto-hepta-methylene was obtained, and Wieland, by using adipic acid instead of suberic acid, obtained the keto-penta-methylene.

The author therefore converted the dimethyl-pimelic acid into the calcium salt, and then subjected this to dry distillation, when a brown oil was obtained having a strong odour of peppermint. The oil was proved to contain a ketone, and since it could not be crystallised, it was converted into the oxide, which was easily purified by crystallisation. The ketone was regenerated from the pure oxide by hydrolysis with hydrochloric acid.

As thus obtained, the ketone is a mobile colourless liquid with a pure odour of peppermint, which is characteristic of these closed chain ketones.

The reaction would be expressed by the following equation:

\[
\begin{align*}
\text{CH}_{2} \text{CH}_{2} \text{CHMeCOO} + \text{CaCO}_{3} \rightarrow \text{CH}_{2} \text{CH}_{2} \text{CHMeCOO} + \text{CaCO}_{3}
\end{align*}
\]

Calcium salt of dimethyl-pimelic acid.

When the ketone was treated with nitric acid vigorous action ensued and oxidation took place, and as a final result a lactone was obtained and two other acids, which have not yet been identified. The oxidation may be supposed to occur in the following stages:

1. The keto group becomes oxised in the usual way to a keto-acid, the ring being broken, the molecule being as follows:

\[
\begin{align*}
\text{CH}_{2} \text{CH}_{2} \text{CHMeCOO} + \text{H}_{2} \text{O} \rightarrow \text{CH}_{2} \text{CH}_{2} \text{CHMeCOO} + \text{H}_{2} \text{O}
\end{align*}
\]

2. On further oxidation the ketonic residue would be oxidised to the carboxyl group, and we should have a dibasic acid, and at the same time the tertiary carbon atom would be oxidised, and the hydrogen be replaced by hydroxyl. Thus:

\[
\begin{align*}
\text{CH}_{2} \text{CH}_{2} \text{CHMeCOO} + \text{H}_{2} \text{O} \rightarrow \text{CH}_{2} \text{CH}_{2} \text{COOH}
\end{align*}
\]

3. This acid, which would be a-hydroxy-a-methylglutaric acid, yields, on evaporation the γ-lactone, which was actually the final product obtained.

\[
\begin{align*}
\text{COOH} \quad \text{CH}_{2} \text{CH}_{2} \text{C(OH)MeCOO} + \text{H}_{2} \text{O} \rightarrow \text{CH}_{2} \text{CH}_{2} \text{COOH} + \text{H}_{2} \text{O}
\end{align*}
\]

The final product of oxidation is therefore the lactone of a-methyl-a-hydroxy-glutaric acid.

THE USE OF BARIUM THIOGUSLATE IN STANDARDISING IODINE.

BY DR. PIMPTON AND J. G. CHORLEY.

The advantages of using this salt are (I.), that it can easily be obtained pure and is of definite composition (II.), and can be kept for a long time. It is best prepared by mixing hot aqueous solutions of barium chloride and sodium thiosulphate, when double decomposition occurs and barium thiosulphate is precipitated as a fine white powder, which is washed and easily purified. The water of crystallisation is not easily driven off, so it is necessary to heat it to 120° for some time before weighing as anhydrous salt.

It should not be drained by the pump or pressed between filter paper, but on drying in the ordinary manner forms a very light powder which mixes very easily with water, and during the titration it gradually disappears owing to the formation of the soluble tetrathionate. It is unnecessary then to add the starch till near the end of the reaction, and thus greater delicacy is obtained.

THE MAGNETIC ROTATION OF THE PLANE OF POLARISED LIGHT IN LIQUIDS.

BY J. W. RODGER AND W. WATSON, B.S.

A new and improved apparatus for determining this constant was described, particular attention being paid to the influence of different temperatures on the liquid under examination. Special methods and precautions had to be taken to avoid errors, and these were described.

The following paper was taken as read:—"Tri-methylsuccinic Acid," by Professor W. H. Perkin, and D. Bone.
Scottish Transactions.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

At the meeting on Friday, March 8, Mr. Alexander Sutherland, President, in the chair, the following papers were read:—

REPORT ON SPIRITUS ETHERIS NITROM.

BY WALTER SMITH.

With a view to ascertaining what practical effect the many papers on this subject had had on the quality of the article as met with in commerce, the author had procured thirteen samples from various retail pharmacists, and determined the volume of nitrous oxide gas yielded by each in accordance with the official method. He had also examined three samples obtained from Mr. Hill, belonging to the series reported on by Mr. Meldrum in December, 1892. The results were as follows:—

<table>
<thead>
<tr>
<th>Sample</th>
<th>Volumes NO Yielded.</th>

</table>

It therefore appeared that only six out of the thirteen samples were above the minimum official strength of twenty-five volumes; while one was slightly under, and the remaining six all far below it. Of the three obtained from Mr. Hill No. 14 was made according to the official formula, and in 1882 yielded 37.3 volumes. No. 15 contained an addition of five per cent. of glycerin, and yielded 38.4 volumes; No. 16 contained ten per cent. of glycerin, and in 1892 yielded 38.8 volumes. It thus appeared that with five per cent. of glycerin the spirit was much better preserved than with spirit alone, and that with ten per cent. of glycerin the results were again much better than with five, but even the addition of glycerin did not appear to be an effectual preservative. These three samples had been kept stoppered and never opened since 1892. He examined the other samples for glycerin, and found it in two. One of these, No. 8, was full strength; the other, No. 4, was a little below the minimum. The foregoing results go to strengthen the view that this preparation should be deleted from the Pharmacopœia or that some better menstruum than rectified spirit should be used as a preservative.

Elderberry Juice as an Indicator.

BY W. B. COWIE.

Having seen the statement in 'Mutens' Analytical Chemistry,' that elderberry juice is recommended by Dr. Hamilton as being the most universally useful indicator for alkalies, being green with them and red with acids, and is in much favour in the U.S.A., I collected a quantity of berries last autumn, and made a juice according to the note. I carefully neutralised the product and used it as an indicator, when I found that it was quite useless as it had very little colour, and but little or no change in excess of an alkali. It occurred to me that the pericarps might give a better colour, and having kept the refuse from the juice, I made a 1 in 5 proof spirit tincture from them, and obtained a rich red colour, which on being neutralised changed to reddish-brown. On using this as an indicator, I found that the colour reactions corresponded to those ascribed to the juice, viz., green with alkalies and red with acids. I have determined the B.P. mineral and organic acids, using it as the indicator and checking with methyl-orange and phenol-phthalein as indicators respectively, and the results were identical. Elderberry tincture forms an excellent indicator in the determination of acids, the change in colour is from red to green, and the end reaction is sharp and unmistakable. On the other hand, when used in the determination of alkalies, the change in colour—from green to reddish-brown, and finally red—is so gradual that the end reaction is very difficult to detect, and it is by no means a good indicator under these conditions. Elderberry tincture is therefore only useful as an indicator in the determination of acids, that is, when an alkali is used as the standard solution.

Types of Branching and Inflorescence.

BY W. B. COWIE.

By means of a series of diagrams the author gave an interesting and very clear description of the different varieties of branching and inflorescence, showing how these were related to the division and subsequent development of apical cells.

The reading of the papers was followed by a discussion, taken part in by Messrs. Cowie, Hill, Lothian, Macpherson, Robertson, Smith, and Sutherland, and on the motion of the Chairman, votes of thanks were awarded to the author.

Reviews and Notices of Books.

The Natural History of Plants. By Kermer and Oliver. Part II. Price 2s. 6d., nett. (Blackie and Son, Limited, London.)

This part of Kermer and Oliver's valuable work deals with various pollination processes, and fertilisation and the formation of fruit in Phanerogams. This interesting part of the subject is treated very fully and in a masterly style, whilst the numerous well-drawn illustrations are adapted to illustrate the text in a highly satisfactory manner. The coloured plate in this part is a brilliant representation of Alpine flowers in the Tyrol.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS

A perusal of this tract leaves on the reader's mind only one clear fact, namely, that the author has been ill: "I had for some months been under medical treatment for the removal of biliary concretions from the gall-bladder and bowels, part of which treatment consisted of rubbing and massage of the abdomen, which I conducted personally; whilst doing this the tips of my fingers were rendered extremely sensitive, and I became, and am still, able to distinguish by the touch, conjoined with internal sensations, the rapid passage of matters, varying in consistence from time to time, through the whole course of the colon until it joins the rectum." And again: "I have, on one occasion, had for a short time complete paralysis of the left arm, which I could distinctly refer to obstructing matters in the colon and higher bowels."

Many discoveries when first disclosed have seemed to the world to be but symptoms of bodily, chiefly cerebral, derangement, and yet in the end they have proved to be true. Whether or no Mr. Fisher's discovery is a symptom or a reality, it is impossible even to surmise, because, for want of a familiarity with anatomical and physiological terms, the description of the observations on which the author founds his views is as yet incapable of being interpreted, and so it is impossible to criticise it. In true Baconian spirit Mr. Fisher has applied experiment to test his theory (whatever this may be). "I have recently had under examination the livers of a sheep, with a large part of the diaphragm attached to them." Thus the author has added a great discovery in anatomy to his physiological triumph. Up to the present time it has been believed that a sheep had but one liver, like the rest of the Vertebrata. Perhaps if Mr. Fisher could spend a year or two in the study of anatomy and physiology he would be in a position to do himself justice in giving his views intelligible form, and showing their relation to established facts of physiological science. It is probable that such a course of study would enable the author to feel the truth of the old saying, Ne etsur supra crepitam. To conclude, the hope may be expressed that Mr. Fisher has by now recovered his health and lost all abnormal sensitiveness.

A MANUAL OF VETERINARY THERAPEUTICS AND PHARMACOLOGY. BY WALLIS HOARE, F.R.C.V.S. Pp. 560. 10s. 6d. (London: Baillière, Tindall and Cox.)

Although it is abundantly in evidence that this book is the production of a master hand, it is to be regretted that its publication has not been delayed to afford a sufficient time for the author to have eliminated the imperfections and supplied some of the omissions, that must detract in no small degree from its value as a text-book for the student and as a reference book for the more advanced practitioner in the science and art of veterinary medicine. As an illustration also of the desirability of a more complete and perfect index the reader does not get...
beyond page 9 without the want of it being brought conspicuously under his notice. A paragraph printed upon this page, referring to pain as a prominent symptom in a variety of affections, states by way of illustration that "it occurs in simple colic, in enteritis, in peritonitis, in volvulus, in affections of the stomach, and also in pleurisy, nephritis, &c." Upon turning to the index with a view of localising this manifestation of pain as a help to diagnose and differentiate between these various ailments, the aspiring student will find to his astonishment and regret that neither peritonitis, volvulus, pleurisy, nor nephritis is to be found therein.

It is, however, more especially in part 3 and in the appendix on Veterinary Pharmacy that this book requires a careful revision. It is palpably incorrect to describe colocyth pulps as the dried fruit of *Citrus vulgaris*. Oleate of mercury is something more than a mixture of yellow oxide of mercury and oleic acid. Sodii bicarbonas is not prepared by saturating carbonate of potash with CO₂. Lin. tereb. alh. does not require the addition of aqua q.s. to convert it into a fluid emulsion. Borax dissolved in water for use as a gargle does not make an astringent gargle. These illustrations may be taken as typical of others that are only too prominent.

New remedies and their doses are fully in evidence; the results obtained by the use of some of them are commented upon. Antipyrene very much takes the place of our older friend, antimony. Antim. tart. is said to be only occasionally prescribed in veterinary practice, and it is further stated that it is difficult to understand how it can be of any therapeutical value. Myrrh is dismissed in two lines; it is no longer associated with its old congener, aloes, or considered to possess any veterinary value in the form of tincture. In concluding this notice the especial attention of the reader is directed to Chapter VII. in part 3, p. 396, dealing with anesthesia and anesthetics, which is eminently praiseworthy, and does honour to the book, to the author, and to the modern humanitarian practice of veterinary medicine.

**Les Droges Simples d'Origine Végétale.** Par MM. G. Planchon and E. Collin. Tome première, avec 626 figures dans le texte, la plupart originales. (Paris: O. Doin. 1865.)

The object of the present extensive work appears to be to combine the classical 'Histoire des Drouges Simples,' of Guibourt, with the 'Tractat Pratique de la Determination des Droges Simples.' The former was an excellent treatise on the commercial drugs of all countries, and was arranged according to the natural orders. In the second the drugs were classified under the different organs of the plant, and it was a most useful handbook for students.

But in order to obviate the inconvenience to students of referring to two distinct works arranged in a different style, Professor Planchon conceived the idea of combining the two works in one, or, in other words, of introducing the histological and anatomical and chemical knowledge of drugs that has been acquired during the last fifteen years or so into the old

'Histoire des Droges,' so as to bring it up to date in pharmaconogy. This work is intended, according to the authors, to form a résumé of the "Cours professé" at the École de Pharmacie de Paris. The wisdom of this plan seems somewhat doubtful. The present volume, which is only the first part, is about the size, or rather larger than, one of the volumes of the original edition of Pereira's 'Materia Medica,' and the entire work will not only be far too cumbersome for use as a student's handbook, but the enormous number of drugs mentioned in it are likely to bewilder the pupil, since there is no distinction drawn, by printing in different type, between the important drugs and those which are little used or rarely seen in pharmacies, even in France. If the latter had formed an appendix at the end of each chapter, they might have rendered the labour of the student and the tax on his memory very much less. The space occupied by them might also have been utilised in giving details of the different qualities and adulterations of drugs, which are neglected, except in a few cases. Of the history of the drugs, or the conditions of climate, soil, and situation in which they grow, practically nothing is stated, nor of the ports whence they come. Moreover, the work is essentially a French one, i.e., whenever the information given is fuller than usual, it relates to the products of French colonies and must be taken to indicate, in all cases, the varieties of drugs met with in the French drug market.

Foreign journals or works on materia medica do not seem to have been consulted, or to a very limited extent.

The progress that pharmaconogy has made in the direction of pharmaco-geographic histology has been fully recognised throughout the work. At the commencement of each chapter a brief summary is given of the chief anatomical details characteristic of the genera treated of. The structure of nearly every drug is described in detail, and the description accompanied by one or more illustrations. The descriptions are, as a rule, minute and accurate. It is to be regretted that in the illustrations a lack of discrimination between the important and unimportant makes itself felt. It may reasonably be assumed that one of the principal objects in illustrating a work of this description is to convey to the reader an accurate conception of cells and tissues that are of diagnostic value or scientific interest; this is precisely what, in many cases, the figures fail to do. For instance, in the case of willow bark (p. 258), oak bark (p. 259), and strychnos bark (p. 663), the attempt has apparently been made to represent an entire section, from cork to cambium; consequently, the scale of magnification must be low, detail is lost, and tissues that are characteristic become inconspicuous or even undistinguishable.

These instances are by no means exceptional nearly all the drugs are treated in a similar manner. The illustrations of powdered drugs might in some measure have supplied this want, but they, unfortunately, are drawn to so small a scale and are so badly printed as to be practically useless, and the reader is, in great measure, dependent upon the text for an
explanation of the histological details. Whilat the student must admire the patience and industry which M. Collin has evidently devoted to the drawings, he will with difficulty restrain a feeling of regret that he has not availed himself of illustrations equally accurate and far more elegant, intelligible, and instructive, that have appeared in the literature of the subject during the past ten years.

It is also to be regretted that the authors have followed the growing practice, of not acknowledging the source of drawings that are not original. Those, or at least the majority of them, in the section on Cryptogamic botany, have evidently been copied from Dallin’s excellent, ‘Traité de Botanique Médicale Cryptogamique’, and some from earlier works. The reader then begins to wonder how many of the subsequent drawings are copied, and how many are original. But there is time to improve the second volume, and it may be hoped that, in a work which is intended to occupy so important a position, the authors will consult the literature that has been published in other countries, and exhibit less of the insularity, so to speak, which our neighbours conceive to be our own special peculiarity.

Correspondence.

The British Pharmacopoeia.

Sir,—In your note to my letter in the Pharmaceutical Journal of the 9th inst., you neither substantiate nor retract the charges you have brought against me in your leader. You are, I think, bound in fairness to do either the one or the other.

T. LAUDER BRUNTON.

* * We regret that Dr. Lauder Brunton should regard our comments as charges against him, but think it undesirable to enter into a discussion of our different opinions.

[Ed. Pharm. Journ.]

Sir,—With reference to the volumetric determination of liq. mag. carb., mentioned in Mr. Lusan’s interesting notes on pharmaooporial revision, I would suggest the use of methyl-orange as an indicator, if such has not been suggested already. Being unaffected by carbonic acid, the determination can be done in the cold. Its inclusion in the B.P. appendix, together with resolic acid, might be useful. In the U.S.P. the most suitable indicator is given in each estimation.

J. G.

A Correction.

Sir,—In your notice of my paper in last week’s issue I observe an error which I think ought to be corrected. The diameter of the supply-tube of the filter is given as 1½ inch instead of ½ inch, and the exit-tube should be ½ inch diameter. As this is apt to be very misleading, especially in the absence of the illustrations, I trust you will oblige me by kindly inserting this correction.

ALEXANDER GUNN.

Sir,—If Mr. Brayshaw will go through the calculation given on page 734, substituting 10°P for 10°S, he will find that the total theoretical COs from 5 c.c. of spirit, is 385 C.c., not 8795 C.c. as he states. The standard I suggest is practically that of the present B.P., and I think the analyses given show it is reasonable.

Birmingham.

J. F. LIVERMORE.
THE PHARMACOPOEIA TEST FOR

PEPSIN.

BY C. D. MOFFAT.

According to the definition given in the British Pharmacopoeia, pepsin should be capable of digesting at least fifty times its weight of coagulated egg albumin when tested in the manner there directed. Since the issue of the present Pharmacopoeia various forms of pepsin have been brought into the market, which according to the point of view, relativley much larger solvent power. The United States Pharmacopoeia defines pepsin as being capable of digesting not less than 3000 times its weight of coagulated egg albumin when tested by the process described in that work. This process differs from that of the British Pharmacopoeia in several particulars, and the question arises as to how far the difference in the solvent power of pepsin, as indicated by these two authorities, may be due to actual difference in strength or determined by the method of testing.

In order to obtain some information on this point comparative experiments were carried out with several samples of pepsin, which were tested simultaneously by the methods of both Pharmacopoeias.

The first sample tried was represented as being capable of digesting 3000 times its weight of egg albumin and, when tested in the manner directed in the U.S. Pharmacopoeia, results were obtained confirming that statement. But when the same pepsin was tested according to the method of the British Pharmacopoeia the results obtained was widely different, and the quantity of albumin dissolved was only 250 times the weight of pepsin used. This difference, which is attributable to the method of testing, shows that the solvent power of a sample of pepsin, as indicated by the process of the United States Pharmacopoeia, would appear just twelve times as great as that indicated by the test of the British Pharmacopoeia. In order to confirm this relation before proceeding further, two other samples of pepsin, which respectively claimed a digestive power of 1:3000 and 1:2500, according to the U.S.P. test, were tested in the standard, and the solvent power was found to be 1:1800 in each case. As these, however, when tested according to the British Pharmacopoeia, both dissolved 150 times their weight of albumin, the first results were substantiated as the table below shows:

For reference the details of the B.P. and U.S.P. tests are tabulated in the next column.

The directions given in the U.S. Pharmacopoeia are so precise that no misunderstanding can occur, but the following particulars as to the manner in which the B.P. test was carried out are desirable.

Vol. LIV. (Third Series, Vol. XXV.), No. 1291.

With the exception of one or two minor details this test is identical with that recommended by Benger (Ph. J. [3], vol. xii., 567), and it was found to answer admirably after several other methods had been tried and discarded; it will, therefore, be briefly described here. The water bath consists of a beaker (5 by 6½ in.), on the top of which is fitted a tin plate, with five perforations, which hold stout test tubes (1½ by 6½ in.), one of which contains the thermometer in 1 fluid ounce of water. The proportions of albumin, hydrochloric acid, and water were in all cases constant, the pepsin being the only variable quantity. This is much preferable to varying the albumin, which would entail a proportional variation of water and acid, comparative results not being then so readily obtained. Since many of the commercial pepsins are now soluble in water, and practically non-hygroscopic, it is most convenient when dealing with one of unknown solvent power to use an aqueous solution of definite strength, the amount of water thus employed being deducted from 1 fluid ounce, as prescribed in the B.P. test, so as to have the bulk of liquid in each case the same, and when examining an insoluble pepsin to dilute with sugar of milk. To ensure the albumin being in as finely divided a state as possible, it is preferable to pass it through the sieve a second time, as recommended by Mr. J. L. Bullock. One hundred grains is then thoroughly triturated with a small quantity of water in a mortar, and transferred to each test tube, particles of albumin adhering to the mortar being washed into the tube with the remainder of the water. Five minims of strong hydrochloric acid are added, and the tubes having been loosely corked and shaken are heated in the water bath until the temperature is constant at 130° F. The several quantities of pepsin are then added, and the tubes kept at this temperature for thirty minutes, each being shaken in turn so as to allow of an interval of five minutes between the individual shakings. At the expiration of the time they are immediately cooled to 60° F., and the quantities of undissolved albumin, if any, compared at once.

I have found the use of corks and shaking preferable to stirring with a glass rod, if due care be exercised, as there is less risk of breaking the tubes, and no difficulty is experienced in dislodging the particles of albumin from the tops of the tubes.

Everyone who has worked at this subject will have experienced some difficulty in getting a comparative reading of the albumin remaining undissolved with the requisite accuracy. This, I find, can be obviated by the addition of a few drops of an aqueous solution of roseine acetate to each tube after the period of digestion has terminated. By means of
the magenta colour thus formed, the relative portions of undissolved albumin are thrown into striking relief, and the boundary between complete and incomplete solution of albumin is accurately defined.

In fixing the solvent power of a pepsin, it is advisable in the preliminary test to use such amounts of pepsin in the four tubes that the relations to 100 grains of albumin may be as 1:50, 1:100, 1:200, and 1:300 respectively. A rough idea can thus be formed of its strength. Thus, if 1:100 has completely dissolved, whilst 1:200 has a considerable amount left, a further test is carried out in the proportions of 1:100, 1:125, 1:150, and 1:175 respectively, the first being useful for comparison. The second test will then determine the exact solvent power.

More than passing allusion to the absolute necessity of strict attention to detail in working at this subject, in order to obtain concordant results, is unnecessary, as this point has been previously sufficiently impressed. The fact has been established that the solvent power of a pepsin determined by the U.S.P. is twelve times as great as when tested according to the B.P. standard, some investigation of the conditions affecting this relation was necessary. These were as follows:

—Acidity, time, temperature, amount of water, and frequency of agitation. The first was soon dismissed, as the B.P. proportion is practically the same as the U.S.P., i.e., 2 per cent. real HCl, and this has previously been shown to be the most favourable.

With regard to time, it was apparent that the proportion of 3000:250 represented numerically the time occupied by the two tests. Of course it was not likely that the relation was really one of time, as there were other conditions at work; still, to clear up this point, a test was carried out with pepsin No. 1 by the B.P. process in all respects, except that the proportion of pepsin to albumin was 1:3000.

The time occupied for complete solution was two hours only. It will be noticed that this test differs from the U.S.P. only in the interval between agitation and the amount of water, which is proportionally about 2.3 times as much in the U.S.P. as in the B.P. The relations between it and the strictly B.P. test are here given.

With No. 6 but little solution of albumin was effected when in the proportion of 2 fluid drachms to 100 grains albumin, and on still further increasing the proportion of pepsin the solvent action on albumin correspondingly diminished. As the menstrum was found, however, to be largely composed of alcohol, it is probable that this had a retarding effect upon the reaction.

It will be noticed that throughout this paper the term "solvent power" has been used in preference to "digestive power," as only in isolated instances was the amount of peptone formed determined, and it would appear that for comparative tests it is unnecessary to proceed beyond the solvent power.

A few words, in conclusion, as to the relative utility of the pepsin tests of the British and United States Pharmacopoeias. In spite of the elaborate nature of the latter, my experience of it is not of a satisfactory nature. An attempt has been made in it to carry out the test under conditions approximating to those at work in the human organism. But it is well to remember that we can never hope
to do this under absolutely natural conditions, and that peptic testing is at the best but comparative. The six-hour test of the U.S.P. is tedious and unnecessary. It involves practically constant attention, and the results when obtained show no compensating advantages over a shorter test at a higher temperature.

The basis of the B.P. test, on the other hand, is workable, and although as it at present stands many loopholes are afforded for discrepancies in results, owing to the idiosyncrasies of different workers, when modified as suggested it will be found to constitute a test which is reliable and readily applicable, and when carefully performed under invariable conditions will be found to give constant results. The objection often brought against it, that the temperature at which it is carried on is above the blood heat, favours of the hypercritical, as for comparative tests this is of no moment. The modifications I should suggest are as follow:—

1. The standard should be raised from 1:50 to 1:250. From an examination of several makers of peptic now in the market, it is evident that no difficulty will be found in procuring a peptic which, under the B.P. conditions of time and temperature, will dissolve 250 times the weight of albumin.

2. There should be a definite interval of five minutes between the agitations. If the albumin be in a properly divided state to start with, shaking is preferable to stirring, since there is always some liability to breakage with the latter.

3. The albumin should be passed through the sieve twice. It will then be in the most favourable condition for the peptic to exercise its solvent powers.

Generally, a more detailed account should be given as to the method of carrying out the test, as it is this want of detail which constitutes a large source of error in a test of this nature, where conditions are little unless the test is carried out under unvarying conditions. The other directions as to proportion of acid, albumin, water, time, and temperature, should remain unaltered.

**BOTANY FOR PHARMACISTS.**

**LABORATORY EXERCISES IN BOTANY,** designed for the use of colleges and other schools in which botany is taught by laboratory methods. By Edson S. Baslin, A.M., Professor of Botany and Materia Medica in the Philadelphia College of Pharmacy, Pp. 540. Illustrated. (Philadelphia, U.S.A.: W. B. Saunders, 1894.)

In the present position of pharmaceutical education, a very considerable difficulty is often experienced by the student in selecting reliable textbooks from the number presented to him. This is unfortunately intensified in the case of the subject of botany by too general a tendency to regard as of subsidiary importance the exact principles of the science, and to lay especial stress on only its pharmaceutical application. The position demands, therefore, that new books, especially when they emanate from a College of Pharmacy, shall be carefully and critically scrutinized before being accepted as trustworthy works of reference for the student.

Regarded from this point of view, Professor Baslin's new work, though admirably got up and containing much that is valuable, must be pronounced as coming far short of present-day requirements. Reading carefully a good deal of the work, the reader is inclined to turn back curiously to the title page to see if the date of publication is not 1875 rather than 1895, so far are modern discoveries and recent views of structure ignored.

At the outset a very different impression is made; the book is said to have had its birth in the laboratory, and it emphasizes strongly and clearly the desirability of studying structure from the plant rather than from books. So clear and definite is the teaching given on this head, that it appears as if it would constitute a most valuable aid to any student who might take it up and follow it. Much of its instruction also is good and sound; it shows the student how to investigate vegetable tissues, and teaches him what reagents to use in his practical studies, and what he may learn from the effects that they produce.

But it is when the author turns to actual botanical teaching a sense of disappointment comes over the reader, which intensifies as the subject is pursued. Botany, anatomy, physiology, all alike contain inaccuracies and leave omissions, which must involve the unhappy student in uncertainty and confusion. The whole work is out of date, old views and modern work are frequently allowed to clash, and the discrepancies remain unexplained.

Criticising the author's morphology first, as this section is the first treated of, one may notice his treatment of the seed. As the fruit is stated to be the ripened pistil, so the seed is called the ripened ovule. A novice must conclude, and very naturally, that the changes in the pistil and those in the ovule are of the same nature, being defined by the same word. But what can be more misleading? Instead of a change chiefly chemical, and involving no morphological alteration, as in the first case, we have in the formation of the seed changes of vast importance both morphological and anatomical. So far from the ovule only ripening, it is the seat of development of the whole gametophyte, the alternation phase of the plant, of the formation and fertilisation of sexual cells, and of the origination of the development of the new sporophyte. In using the phrase "the ripened ovule," as defining the seed, the author is guilty of false morphology. The seed is, in fact, the young sporophyte, embedded in, or attached to, the gametophyte which gave it origin, and surrounded by the remains of the original macrosporangium in which the macrospore was formed. To call it a ripened ovule is to ignore the fact that the spore is a definite stage in the life history of the plant. If the phrase "ripened ovule" can be admitted at all, it must apply to it at the time when the spore or embryo sac has reached its full development, and before it germinates to produce the gametophyte.

In the description of the corona of Narcissus, the morphology given is at variance with the usually accepted ideas of leaf structure. This, like the scales in the corolla of Caryophyllaceous flowers and the ligules of grasses, is said to be stipular in origin, though it arises as they do at the summit instead of the base of the petiole.
Adventitious and secondary roots are said to be the same, and the author holds that the branching of the root is generally without any definite order. But it is in the section dealing with anatomy that the greatest errors are to be found. The most glaring of these is the reiteration of the old ideas of the structure of the bark, in both stem and root.

If anything in the structure of the axis has been ascertained more clearly than another by modern work, surely it is that the bark is a secondary formation, that is it is not a thing added on successively to the cortex and bast of the stem, and generally in the pericycle of the root. Yet the author gravely puts forward the old views of corky layer, cellular or green layer, and liber layer of the bark, saying that all external to the cambium must be regarded as belonging to it. In describing the stem, on p. 496, he finds himself in the curious position of speaking of the middle or green layer, while saying that outside it is only an epidermis. Where are the other layers here? How can there be a layer properly called a middle layer, when no other layer is either outside or inside it? From the mode of its formation, bark is necessarily dry and dead. Yet the author describes the dandelion root as having a succulent bark, containing numbers of latexiferous vessels.

It would take too much space to criticise in detail all the erroneous statements in the book. There is an absolute silence about the theories of axial structure, which have now for some three or four years taken the chief place in modern textbooks; the pericycle is not even alluded to, nor is the central cylinder or stele of the axis described as an anatomical region. The endodermis is dealt with as if it belonged to a vascular bundle and not to the stele, while the attempt to find a central cylinder in the stem of the fern, now recognised almost universally as polyetalic, lands the author in a maze of difficulty. The anatomy of the root is represented as based upon a single vascular bundle with many rays, instead of upon a central stele with alternating alternate bundles of wood and bast.

Where the author incidentally throws light upon physiological conceptions he is still more unhappy. He speaks of root hairs covering the whole surface of young rootlets, whereas they are confined to a definite portion. His interpretation of the structure of stomata and explanation of their mode of action, on page 322, may be quoted as a special instance of his looseness of reasoning. He admits that the outer surfaces of the guard cells are thickly cuticularised, and that only their radial walls (i.e., those abutting on the other epidermal walls) are thin. Yet he gravely says they take up water from the watery vapour of the air by their hygroscopicity! This is exactly what they do not do, the entry of water being always through the thin radial wall by osmosis from the other epidermal cells. Why on his theory are the guard cells supplied with chlorophyll when the rest of the epidermis has none?

It is a grave pity that a book like this should go forth to the average elementary student under the authority of a Professor of Botany and Materia Medica. It will do more to perpetuate the old errors that modern research has demonstrated to be such than it will good in directing students in the proper methods of study.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

which the requisite mineral manures are added and the nitrogenous matter is given in the form of nitrates, the cereals make growth and attain vigour in direct proportion to the amount of nitrate given to them when the quantity provided is small. So that a double dose of nitrate causes the growth of a two-fold amount of organic matter, a treble dose gives a three-fold increase, and so on, until that amount of nitrate has been added which enables the plants to grow to their normal size, when, of course, the further addition of nitrate has less and less effect upon the amount of organic matter produced. The cereals are thus able to assimilate the nitrates directly, and the growth of these crops in a soil otherwise fertile was found to depend precisely upon the amount of nitrate present. With the leguminous plants no such correspondence was observed. Their growth was quite capricious, and, indeed, sometimes the soil containing the least amount of nitrate would produce the largest and healthiest plants. Many experiments at length led Hellriegel to the conclusion that it was the free nitrogen of the air which constituted the store from which leguminous plants derived their nitrogenous nourishment.

If we accept as correct Hellriegel's conclusion that leguminous plants differ from others in that their roots are furnished with nodules which are the seat of changes due to micro-organisms, whereby albuminoid matter is stored up from the assimilation of free nitrogen, either in the air of the soil or in that of the atmosphere, the question still remains whether the bacteria coming from the soil or the micro-organisms in the nodules are the actual carriers of nitrogen to the plant, or even whether they stimulate the plant in such a way as to enable it to take up free nitrogen by its leaves or otherwise. The experiments of Berthelot and André indicate that, altogether apart from the growth of leguminous plants, some soils are capable of absorbing the free nitrogen of the air. In such cases the gain in nitrogen is associated with a growth of organic matter which has been proved to be due to the presence of small unicellular Algae. Frank, of Berlin, after years of study, has concluded that the root-nodules of leguminous plants are not the cause of the capacity to absorb nitrogen, but are rather the result of that process. He accepts Berthelot's doctrine that small cryptogamic plants, such as certain Algae, are able to assimilate free nitrogen, and that the organic nitrogen in the soil is due in some measure to their growth, but he sees in unicellular Algae, small plants that may be compared with the ordinary chlorophyll-containing cells of green-leaved plants in general, and he is of opinion that the seat of the assimilation of free nitrogen is to be sought in the chlorophyll cells, where it was long since demonstrated that the seat of the decomposition of carbonic acid and the fixation of carbon is to be found. He would admit of no difference between leguminous plants and others as regards their capacity to assimilate free nitrogen in their chlorophyll cells, though he acknowledges that the Leguminose possess this power in a very remarkable degree. He is, therefore, of opinion that, while fallow land, poor

in organic matter, may become richer in nitrogen through the growth and nitrogen-assimilation of minute cryptograms therein, yet the enrichment is greatly augmented when plants of a higher order are grown upon the land. Some orders of plants, like the Leguminose, may assimilate so much nitrogen from the air as to leave in their roots and stabkle when the crop is removed more nitrogen in the form of nitrogenous organic matter than was thus previously. Others, such as the cereals, may assimilate so little atmospheric nitrogen, and make at the same time such demands upon the nitrates in the soil, as to leave the land poorer when the crop is taken off. Between these extremes come all manner of crops which, especially in the later stages of their growth, undoubtedly assimilate free nitrogen, but whether the amount thus assimilated will cause them to be ranked agriculturally as nitrogen-collectors or as nitrogen-consumers must depend upon the greater or less extent of their leaf surfaces, and the consequent multitude of chlorophyll cells exposed to the air, besides, probably, upon specific differences in the ability of the chlorophyll cells to assimilate nitrogen in the various orders of plants. Such, in brief, are Frank's views, which, it need hardly be said, are being warmly controverted by various distinguished chemists and botanists.

It was the splendid achievement of the philosophers at the close of last century to demonstrate the means whereby plants are able to acquire their carbon. A later comprehensive survey of the conditions of life upon the globe showed how animals and plants are associated in the alternations of oxidation and reduction in which that element takes part. It would seem that at the close of the present century we are on the eve of solving that still more difficult problem—of profound interest to the agriculturist—concerning the history of nitrogen as it fluctuates between what are known as the organic and inorganic divisions of matter upon the earth.—Times.

DRUG GRINDING.

BY CHARLES A. THERR, B.S.C.

This venerable and necessary art has been in use from time immemorial, and in many cases we still follow in the footsteps of our forefathers by strictly adhering to the most crude methods imaginable. Strictly speaking, drug grinders may be divided into two classes—1. Those who grind materials for their own use, and, 2. The drug miller, whose chief occupation consists in grinding other people's drugs at so much per pound.

Of the former little need be said—the goods belong to them, they grind according to the convenience of the moment, and generally giving themselves marked satisfaction.

With the latter the case is entirely different. Competition is keen, and customers are very particular as to the weight, colour and aroma of various goods returned—they sometimes also expect impossibilities. Before going further, it may be distinctly understood that the drug miller, in order to be successful, must be acquainted with machinery and botany, and likewise have a general chemical knowledge, relying
entirely on this, together with experience, for drug grinding is ignored in books.

1. Drying is in most cases necessary, as no fine powder can be made from damp goods. Overheating must be guarded against, as both colour and aroma are soon ruined, notably in opium, aloes, rhubarb, orris. Heat is not so necessary as good ventilation. One hundred degrees of the former and plenty of the latter are safe quantities. The loss in drying is of course dependent on the state of the goods received, yet it is a hard matter to convince customers that opium will lose 20 per cent., soap 35 per cent., or green quassia logs 50 per cent. It is likewise difficult to assure them that Cape aloes sometimes contain 25 per cent. of stones, but such is a fact.

2. Crushing.—Few things need crushing before powdering, with the exception of very coarse or heavy substances, the grinding being done at once. Still, when necessary, heavy disintegrators or regular crushers are used.

3. Grinding.—Just at this point is where experience is necessary. Take seeds as an example. If fine powders are required, one's ingenuity is taxed to the utmost. Hardly two need exactly similar treatment, and even the same seed will require different mechanical division if wanted for oil preparing or the general powdered article. Croton and stavesacre seeds, if for oil expression, are most conveniently pulped—not powdered—under fairly heavy Putty chasers, whereas a disintegrator with fine screens, is the correct machine to use for the ordinary powders. Fenugreek and corianders can also be ground in these machines, but need final homogeneity under edge runners, otherwise the powder appears to consist of husks. Cardamoms require the edge runner only, whereas aniseed, caraway, and fennel are only ground to advantage under seed roller mills. Nux vomica seems, by common consent, to need steaming. It is difficult to understand why, as there is a very good machine on the market capable of grinding 150 pounds per hour, the powder passing through a 90 degree mesh. Mustard is generally powdered under stampers. A well-equipped drug miller's establishment is not a plaything, for, besides plenty of power and all the paraphernalia required to carry on the processes mentioned, there are exhaust fans, decorticators, saws, and chipping machines to be taken into consideration. One of the worst drawbacks—and, unfortunately, the most common—is overcrowding. I once visited an establishment where sang draconis, tumeric, gum arabic, and capsicum were being ground in adjoining machines. The following should find room in all first-class establishments, the number being dependent on the amount of work calculated: First—Disintegrators, with six or eight light iron beaters on each, and movable screens speeded up 2000 to 3000, according to size. These machines are most suitable for roots, barks, some seeds, leaves, capsi- cums, cantharides, etc., and are, moreover, easily cleaned. Second—Burr stones (horizontal), for salts, as alum, sal Rochelle, black antimony, etc. Third—Pebble mills, for small quantities of poisonous goods, and where time is no great object. Fourth—Seed roller mills, mostly for the very oily varieties; speed low. Fifth—Granite edge runners, five feet in diameter, ten degrees (!) wide, speed 30, for high-class powders, such as best gums, orris, or goods in which colour is a great consideration, notably rhubarb, gamboge, sang draconis, opium, aloes, etc. Sixth—Small stone edge runners, about two feet, speed 40; for all light and friable articles. Seventh—Putty chasers, for coarse work.

4. Mixing.—It is self-evident that as the soft parts of a root or bark are at once reduced, whereas the harder particles remain till the last, the necessity of this process is obvious. A practical man generally devises his own machinery, yet the market is full of good ones, and this is no source of trouble.

5. Sifting.—For large quantities a bolt is preferable to anything, but for poisonous substances there is nothing to equal the "drum sieve." Above all, it is well to remember that all powders need sifting.

6. Finishing.—That is a question of taste, but all brown paper bags should be lined with white or blue paper.

Finally, drug grinding must be looked upon as a combination of scientific and artistic attainments. Everyone who is at all anxious as to his goods should carefully examine them on return. The test is simple—a sense of smell, a magnifying glass and searching physical properties.—Drug Reporter.

THE ACTIVE PRINCIPLE OF RHUS TOXICO- 
DENDRON AND RHUS VENENATA.

Dr. Pfaff, in a paper read before the American Physiological Society, stated that his experiences had been made with the assistance of S. Sanford Orr. He said that it is the general opinion that R. toxicoDendron and R. venenata contain a volatile proximate principle, which causes the well-known dermatitis venenata. Malach's toxicodendric acid has been generally accepted as the active poison. Pfaff and Orr could not believe that a very volatile substance is the cause of the trouble, as this would be contrary to the pharmacology of vegetable skin irritants. They isolated Malach's toxicodendric acid in the form of the barium salt, and found it non-toxic. The same is true of a solution of the free acid in water. As the real active principle they found a non-volatile oil. This oil, when applied to the skin, causes the well-known eruption. Photographs demonstrating the effect of the oil upon the human skin were shown. As preventive treatment Pfaff and Orr proposed a thorough washing with water, soap, and brush, or, still better, a repeated thorough washing with an alcoholic solution of lead acetate. The oil being soluble in alcohol, and then forming a nearly insoluble lead compound, is thus best removed from the superficial skin. Further investigations will be undertaken, and an attempt made to classify Malach's toxicodendric acid and the new poisonous oil, which seems to be of the kind called cardol, obtained from Anacardium occidentale. These two oils are, however, not identical.—Science.
BACTERIOLOGY IN ITS PRACTICAL ASPECTS. *

BY R. T. HEWLETT, M.D. LOND.,
Demonstrator of Bacteriology in King's College, London.

It is difficult to define exactly what is meant by bacteriology. This term is now used in a comprehensive sense, equivalent to micro-pathology and even micro-biology, for all investigations connected with micro-organisms, vegetable and animal, are included under it. Bacteriology, however, especially deals with micro-organisms in their relation to processes, disease, fermentation, putrefaction, and the like.

Commercially, micro-organisms are of the utmost importance, and this is daily becoming more and more recognised. When you consider that the beer and wine industries owe their existence to the activities of micro-organisms, that the fertility of our lands is largely due to nitrifying micro-organisms in the soil, that sheep-farming and the silkworm industries in France were once threatened with extinction, the former owing to the ravages of anthrax, and the latter to a disease of the silkworm known as pébrine, you will see that this statement is perfectly true.

Commercially too, bacteriology is important. In brewing, for example, it is found that occasionally abnormal conditions arise technically termed "diseases," which cause considerable loss. It has been demonstrated that some of the worst of these so-called "diseases" of beer are due not to faulty manipulation or to the use of bad materials, but to the entrance of extraneous micro-organisms. Thus, certain "wild" yeasts produce imperfect clarification and bitter taste, a saccharine causes a bitter taste and disagreeable smell. To remedy these evils bacteriology has stepped in, and by certain methods it is possible to purify the yeast and to obtain cultivations of yeast bacteriologically pure, that is, containing only a single species of yeast and free from bacteria.

These pure cultivations of yeast are being largely employed on the Continent, and their use is now being introduced into English brewing practice. For the ravages of anthrax and pébrine, through the genius of Pasteur, bacteriology has likewise found remedies. I do not, however, intend to dwell on this aspect of my subject. I wish rather to deal with bacteriology in its relation to everyday medicine and surgery, in its relation to the diagnosis and cure of disease.

Experimental bacteriology has a great deal to tell us about the groups of substances known as antiseptics, for example, by bacteriological methods we are enabled to accurately estimate the value of various disinfectants and antiseptics.

First of all, with regard to antiseptic treatment, most are agreed, I think, of the value of that treatment for wounds, either surgical or accidental, may I suggest that any antiseptic system adopted, to be efficient, should be as simple as possible and free from complications. The use of antiseptics, like everything else, should be tempered with judgment and common sense. We all know that fatal poisoning by carbolic acid, iodiform, and corrosive sublimate, used as antiseptic dressing has occurred, and I have heard of such accidents as slaughtering and the like following a too vigorous application of certain antiseptic lotions. With regard to the merits of antiseptic versus aseptic dressings, that is, dressings impregnated with an antiseptic, or dressings simply rendered sterile by heat, I would mention that as it is impossible to altogether exclude micro-organisms from wounds it would seem to be desirable to employ antiseptic dressings; the antiseptic constituent of these will then inhibit the growth of organisms if they be present, which would not be the case with aseptic dressings, sterilised wool, and the like.

To me it seems certain that the aseptic system must break down occasionally, no matter how carefully carried out, and that the antiseptic system is theoretically the only logical one, and practically the safer in the long run. Apropos of surgical antiseptics, it is worthy of note that dilute solutions of corrosive sublimate are by no means stable. Vignon and Buckler have found that aqueous solutions of corrosive sublimate of a strength of 1 in 1000 prepared with distilled water, and in the absence of light and air, undergo little change, but exposed to air, the strength diminishes; prepared with ordinary tap water, a considerable proportion of the corrosive sublimate is decomposed; the addition, however, of small quantities of hydrochloric acid (5 Cc. per 1000 Cc.) renders such a solution quite stable. The addition of the acid would not, I think, interfere with the antiseptic action, and its presence would prevent precipitation by albumin.

Some recent researches showing that the potency of antiseptic solutions may be markedly increased by raising their temperature, somewhat seems to be of practical importance. Heider found that spores of anthrax survived an immersion of thirty-six days in 5 per cent. aqueous solution of carbolic acid at the ordinary temperature, but were soon killed when the temperature of the same solution was raised to 55° C.

Chamberland and Fernbach also found that solutions of sodium hypochlorite, chloride of lime, and peroxide of hydrogen were much more potent at a temperature of 40°-50° C. We may have a practical example of the application of these facts in the treatment of diphtheria. Here local treatment is of the utmost importance, and we can increase the activity of our antiseptic paints and gurgles without increasing their strength, which might be dangerous, by employing them hot, say at a temperature of 45° C. In surgical practice, hot lotions are of course better for the patient, and we see that they have the additional advantage of being more potent germicides. It has also been shown by Lent that some substances have a powerful inhibitory action on antiseptics, and may render them inert. Tested on anthrax spores, carbolic acid in olive oil has no disinfecting action, and alcohol and glycerin, when present in large quantities, markedly interfere with the activity of corrosive sublimate and carbolic acid. This is another noteworthy point, seeing how often glycerin forms a constituent of antiseptic throat paints and gargles.

Antiseptic treatment in acute infectious diseases where it would seem to be especially indicated, has

* Read before the Harveian Society of London, November 1, 1894.
failed, and for this reason, that it is impossible to introduce any known antiseptic into the body in sufficient quantity to act as a germicide without danger. It is only where there is some local seat of disease which can be got at that this form of treatment is of any avail, and even here there may be limitations. In enteric fever and cholera, for example, antiseptic treatment is indicated, and may be of service, the difficulty being, however, to get the antiseptic through the stomach into the intestines. In cholera the vomiting and purging are also disturbing factors.

Diphtheria and tetanus are two diseases in which the micro-organisms that produce them are localised, the general symptoms being due to the absorption into the circulation of toxines elaborated by these organisms. In each of these diseases local antiseptic treatment should be useful; in diphtheria it is usually adopted in some form, and should, I think, be persevered with; in tetanus it is probably wiser to treat radically, and to remove the local lesion by excision or amputation, but if this be inexpedient or impossible for any reason, then it would seem to be desirable to inject an antiseptic. Experimentally, it has been shown that iodine has a powerful effect in destroying or rendering inert the toxines of the tetanus bacillus, and I would suggest that a solution of iodine might be valuable in treatment, both used locally and, perhaps, internally.

To bacteriology we owe the development of the promising antitoxic treatment. An animal is treated with gradually increasing doses of the toxine of tetanus, for example, and in time acquires a very high degree of insusceptibility to the disease. The blood serum of such insusceptible animal possesses the remarkable property of curing the disease in other animals and in man. Such a curative blood serum is termed an antitoxine. Here, too, there are limitations—the more acute the case and the longer it has lasted the greater must be both the activity and the amount of antitoxine injected, until finally the dose necessary for cure may become an impossible one.

Some very striking results have been obtained in diphtheria and in tetanus by this treatment. Experimentally the antitoxines have a marvellous power. In tetanus, for example, with which I have chiefly worked, minute doses (1/200 C.c.) of the antitoxine blood serum will render a guinea-pig immune to ordinarily fatal doses of the tetanus toxines. Mixed with the toxines the serum renders them quite inert.

More striking, perhaps, than the curative effect is the immunising power of the antitoxines, and if our hopes are realised, a wide field of practical application is opened out. Moreover, the antitoxines seem to be harmless, so that they will be used in suspected, as well as undoubted cases of disease.

Bacteriology has given us improved methods of diagnosis in several instances. The examination of sputum for tubercle bacilli is now daily practised, and is of the greatest value, for in many instances where physical examination leaves the diagnosis doubtful the finding of bacilli will settle the matter. It must always be remembered that while the presence of tubercle bacilli is proof positive, failure to find them by no means indicates that the case is not tubercular.

(To be continued.)

CINCHONA GATHERING IN PERU.

The mountains of Peru form the natural home of the cinchona-tree, which is easily distinguishable from surrounding foliage by its beautiful leaves and magnificent proportions. The trees themselves frequently attain a height of eighty feet, are straight as a lance, and covered with foliage. The leaves are large and of a deep glossy green, relieved by delicate pink lines. The life of a bark-hunter is one of constant toil and incessant hardship, and his main reliance on his long and solitary journeys in search of the bark is the coca leaf, which he masticates for the strengthening and stimulating qualities it possesses. Since the days of the Incas this coca has been in common use locally, and it is said that among the mountains of Bolivia and Peru, Indians using coca freely when driving pack mules over the roughest roads along the Sierras outstrip well-mounted horsemen. From thirty to fifty grammes are consumed daily, serving both as food and stimulant. The cacarillo, constantly using coca, finally loses the senses of taste and smell. There are many varieties of cinchonas, which the hunter learns to distinguish through the texture and appearance of the bark. They are red, white, orange, yellow, blue, and grey; the yellow being the finest. Although the pay of the quinine-hunter is very small, it suffices to meet the simple requirements of himself and family, and as a class they are happy and contented with their lot. It is a vocation that is handed down from father to son, but despite long years of experience, coupled with an intimate knowledge of the intricate trails leading to the cinchona tree, the Indian hunters frequently lose their lives in the jungles of the wilderness. Occasionally, a number of hunters start together as a greater protection against disaster. Upon reaching a desirable spot where the signs of paying trees are considered good, preparations for camping are at once made, and from the tops of the loftiest trees the hunters scan the forest, quickly recognising the cinchonas. The task of gathering cinchona bark occupies all the working hours between sunrise and sunset. Armed with knives and keen-edged hatchets, the tree is quickly felled and the trunk is stripped and cleared from all foreign growth. This is a task of considerable magnitude, frequently requiring days of constant labour, the sharp edges of lance-like leaves, mingled with thorns and briers, lacerating and wound- ing the hunter's flesh. The bark, when removed, is cut into small curling slips and piled up in a convenient spot, where they are subjected to a drying process. The thin portions of the bark curl up, drying rapidly, while the larger and thicker strips retain their shape and are easily packed for transportation. When all is pronounced ready by the toriago, or head hunter of the party, the bark is neatly lashed together with plaited grass and bound round with broad tough leaves, as a protection to the cured bark. The Indians and peons then shoulder their burdens, often weighing as much as one hundred and fifty or two hundred pounds—these are kept in position by plaits of grass passing round the foreheads of the bearers, and are thus carried to market.—Journ. Soc. Arts.
POISONING IN SCOTLAND.

A supplement to the thirty-eighth annual report of the Registrar-General for Scotland has just been issued, in which some information is given as to the number of deaths caused by poison during the ten years 1881-1890. Unfortunately, it relates only to cases of suicide by poison, and no details are given in regard to the cases of poisoning by accident. But it is satisfactory to learn that, even among suicides, poison has been the cause of death only in a comparatively small number of instances. During the period of ten years there were, according to the report, in all 2146 cases of suicide, 1496 males and 651 females. Out of that number the number of cases in which poison was employed was 233, or rather more than 10 per cent. of all the deaths by suicide.

Among the poisons employed for suicidal purposes, opium, morphine, and their preparations were, as is usually the case, the most frequent cause of death, the number being altogether 106, or rather more than 45 per cent. In thirty-three instances the nature of the poison causing death is not stated. Of other scheduled poisons, prussic acid is stated to have been the cause of death in eleven instances; oxalic acid, nine; strychnine in eight; arsenic in seven; chloral hydrate, six; potassium cyanide in five; chloroform, three; corrosive sublimate, two. The number of instances in which articles not in the poison schedule have been the cause of death is forty, and of that number sixteen are attributed to carbolic acid.

Although unconnected with the subject of death by poison there is an interesting feature of this report which is worth drawing attention to. It is the comparison instituted between the death rates obtaining among persons engaged in different occupations. Seventy-three occupations have been selected for the purpose of the comparison, and the relation between them is expressed by the comparative mortality figure computed from the death rates in each occupation, and representing the mean mortality of males between the ages of 25 and 65 engaged in any occupation, as compared with the mortality of all males of similar ages in Scotland, the latter being taken as 1000. From this comparison it appears the chemists and druggists occupy a medium position, the comparative mortality figure being in their case 925, while that of hotel keepers and publicans is as much as 2306. Chemists and druggists stand 36th on the list; and it is of interest to note that while clergymen are 59 on the list, with a comparative mortality figure of 561, physicians, surgeons, etc., are 18 on the list, with a comparative mortality figure above the average, of 1109. With persons engaged in agricultural pursuits the comparative mortality figure is still more favourable.

THE DANGERS OF COMPRESSED GASES.

The list of fatalities from accidents to cylinders containing compressed gases has been increased by a case presenting unusual features. On Friday, 16th inst., a gardener named Holbrook was blown to pieces at Fenchurch Street Station, London, by the explosion or bursting of a cylinder containing compressed oxygen. The cylinder was guaranteed to be of best soft steel, had just been refilled by Messrs. Clarkson, of Holborn, for Messrs. Newton and Co., opticians, Strand, and was sent out with a certificate stating that it had been tested up to a pressure of 3500 pounds to the square inch. It is understood that the contained gas was under a pressure of 1800 pounds only. Holbrook was sitting down at the station with the cylinder resting beside him upon the wooden seat. Suddenly a loud report was heard, and Holbrook was found dead and badly mutilated, whilst considerable damage was done to the station. The Daily News, commenting upon the accident, remarks that there are two great dangers from which those concerned in the production of limelight and using cylinders containing compressed gas have to be guarded —the liability to explosion should the oxygen come into contact with hydrogen, and the possibility of a cylinder bursting should it be unable to withstand the pressure of the highly compressed gas within. In the former case there would be an explosion properly so-called, while in the other, though equal damage might be caused by the velocity with which the fragments of steel would be propelled through the air, there would be no combustion. Some eye-witnesses of the disaster allege that they saw a flame, and such testimony is incompatible with the theory that the cylinder simply burst. In the Leeds case (vide Ph. J. [3], xxiv., 417, 438, and 528) it was shown
that the cylinder was not made of suitable metal, but manufacturers now take the most elaborate precautions to render accidents from that cause impossible. Great attention is paid to the quality of the steel, which is carefully annealed, and each cylinder is tested to withstand a pressure considerably greater than that to which it is intended to be put. These precautions having been taken, it is alleged that the charged vessels can be dropped with impunity. On the other hand, considerable caution is exercised to avoid the mixture of gases, the manufacturers being careful to manipulate the two gases in distinct parts of their premises. It is possible, however, that there may be left in an empty cylinder a residue of one gas sufficient to occasion an explosion should it be re-charged with the other. Of late years, therefore, the precaution has been adopted by some dealers of painting vessels intended for one gas black, while vessels intended for the other are coloured red. As a further precaution it has been suggested that the pressure of contained gas should not exceed one-sixth to which the cylinders have been tested, but it is questionable whether harm may not be done, by weakening the vessels, by testing to such extreme limits. The strain caused must be exceedingly great, and at best it cannot be guaranteed that the cylinder will bear such a strain, or even one approaching it, again. This point seems worthy of consideration, and it will be a distinct public advantage if the inquiry into the matter should result in the cause of the disaster being precisely indicated, so that more definite precautions may be taken to avoid the repetition of similar disasters.

ACTIVE PRINCIPLES AND GALENICAL PREPARATIONS.

Under this heading Dr. Ralph Stockman contributes an article to last week’s British Medical Journal, in which he re-states the well-known, and yet not too well-known, fact that from a therapeutic point of view it is not always preferable to use pure active principles in place of galenical preparations. When, for example, the general action of morphine and quinine is desired it is most advisable to give them pure, “as they are then more easily administered and more quickly absorbed, and in consequence the beneficial effect is more rapid and decided.” When, however, it is desired to act on the alimentary canal, opium or its galenical preparations are considered superior to morphine, and the same is true with regard to quinine and the preparations of cinchona bark. Kino and catechu again act better as intestinal astringents than pure tannic acid. It is suggested, however, that ointment of galls might be made with tannic acid, that elaterin and aloin should replace elaterium and aloe, respectively, that galenical preparations of nux vomica should be relinquished in favour of strychnine, whilst atropine might possibly be generally substituted for belladonna. Reference is made to the fact that certain drugs in common use contain different principles which act in an antagonistic manner, and that accordingly those drugs and their active principles cannot be used indifferently. It might also have been shown that this indicates that chemical knowledge of the drugs in question is in advance of pharmacological knowledge, for, as Dr. Stockman remarks, medical practitioners are often very much in the dark as to the actual cause of the effects produced in such cases. On the whole, it cannot be said that beyond stating these facts Dr. Stockman has added much of value to the discussion on the revision of the Pharmacopoeia.

THE PROVINCE OF PHARMACOLOGY.

In an inaugural lecture on “Pharmacology and Therapeutics,” since reprinted, Dr. J. B. Bradbury, Downing Professor of Medicine at the University of Cambridge, expressed the opinion that the province of the pharmacologist is to be a forerunner of the physician, pointing out the therapeutic indications of new remedies and an extended or more rational use of old ones. Though a perfect pathology and pharmacology (if attainable) might lead to a perfect therapeutics, they could not replace it. A firm foundation may be laid by them, but the superstructure must depend upon the individual tact and experience of medical practitioners.

SCOPOLAMINE.

The Apotheker Zeitung of 16th inst. contains an interesting note on “Scopolamine Hydrobromide” by Dr. O. Hess, in which he states that he has reason for believing that it is a mixture of the salts of two distinct bases. One of these bases is described by Dr. Hess as being identical with the hyoscine which has long been known. The other base is isomeric with hyoscine, and Dr. Hess proposes to name it atroscine. The proportion of the salt of this latter base in ordinary scopolamine hydrobromide varies from 11 to more than 50 per cent., and the preparation of the two salts in a state of purity is stated to be free from difficulty. Further information on that point will be furnished shortly by Dr. Hess.

THE ANNUAL DINNER.

Gentlemen willing to act as Stewards at the Annual Dinner are requested to send their names to the Honorary Secretary, Mr. Richard Bremridge, 17, Bloomsbury Square, W.C., without delay, in order that they may be included in the first list, which will be published next week.

PROCEEDINGS UNDER THE PHARMACY ACT.

On March 20, at the County Court, Carnarvon, before His Honour Sir Horatio Lloyd, M.P.P., Evans and Laker, not being registered chemists and druggists, were sued by the Pharmaceutical Society of Great Britain for a penalty of £5 for keeping open shop for the sale of poison, namely, Fellows’ syrup, on January 2 last. Judgment was deferred. A full report will appear in our next issue.
Proceedings of Societies in London.

THE WESTERN CHEMISTS' ASSOCIATION
(OF LONDON).

A meeting of this Association was held at the Westbourne Restaurant on the 20th inst., the President, Mr. Parker, in the chair. There was a representative attendance, and after the minutes of the previous meeting had been read and confirmed, Mr. W. Martindale, was called upon to open a discussion on the forthcoming new edition of the British Pharmacopoeia.

Mr. Martindale prefaced his remarks by saying that they represented his own views only, for, although a member of the Pharmacopoeia Revision Committee of the Pharmaceutical Society, no work had yet been done in that capacity; consequently he was not breaking any confidence. He considered the subject of weights and measures to be the most difficult point in the revision of the B.P., and the more we take into consideration the fact that the metric system of weights and measures has been adopted by every civilised country, with the exception of Great Britain and Russia, and that, with the exception of our own, every pharmacopoeia employs the metric system exclusively. Hence, unless the latter system be adopted, we are in danger of losing a great part of our export trade with the various countries where the metric system is in force. If, however, the metric system were adopted the system of measuring liquids, as partially adopted in the Supplement to the French Codex, would have to be used. By adopting the metric system the relations between liquids by measure and solids by weight would be clearly defined, but the doses would have to be stated in both the English and metric systems for the convenience of prescribers. Decimal proportions should be as much as possible adhered to. For example, tincture of opium might be made 1 in 10, using crude opium, and standardising the tincture to contain 1 per cent. of morphine. The various classes of remedies in the B.P. were referred to under the following heads:

Acids.—The present group of liquid acids is both inadequate and redundant. Some are too weak, such as nitric and sulphuric acid for caustics, and hydrobromic and sulphurous acids can be obtained in a concentrated form for preparing the official acids in a much purer state than is at present directed. Acetic acid is redundant. We now have three acids, where two would suffice, as the ordinary acid is made commercially by diluting the glacial acid. Acetum, if retained, should be free from sulphuric acid. Liquor acidi chromici seems unnecessary, as it is too weak to be used for the purpose of a caustic. Carbolic acid should be designated Phenol, or better Carbol, to indicate its origin.

Ether.—The ether '735 is too much diluted, both by alcohol and water. The gravity should be raised to '725, whilst it would be advisable to introduce an ether prepared from methylated spirit, e.g. '717 to '720, to use for testing and some manufacturing pur-poses. The retention of Hoffman's anodyne will have to be decided in deference to medical opinion.

Ammonium preparations.—The weaker solutions of citrate and acetate of ammonium should be expunged.

Alcohol.—The plan followed in the French Codex of indicating various strengths of alcohol as the prescriber may require, is favoured. They are made by diluting alcohol containing, say, 95 per cent. by weight. Methylated spirit free from mineral naphths, for external application, should be recognised.

Aqua.—The distilled waters of orange flower, elder flower, and rose, are objected to on the ground that they can only be prepared at one season, and two are foreign products. All three are apt to become fungoid. The process of the Japanese Pharmacopoeia for preparing them is preferred. It consists in agitating the essential oil of the drug in question with boiling distilled water. Camphor water should be of definite strength.

Cachets and Capsules should be recognised.

Collisions might be extended as a class. The formula for simple collodium needs careful investigation to determine the best proportion of alcohol, ether, water, and pyroxylin to use, so that a transparent, contractile, and non-brittle film may be produced.

Confections.—Only confection of sulphur and confection of senna appear worth retaining.

Decotions.—A uniform direction applicable to the whole of this class of preparations is advisable. Thus, boil 1 part of the drug in 30 parts of distilled water for 10 minutes; strain, and pour enough distilled water over the strainer to make up to 20 parts. This is a modification of the plan adopted in the French Codex, and could be adapted to unofficial drugs.

Elizirs.—Formulae for these might be admitted.

Emplastrum.—These are unnecessarily complex.

Enemases.—These seem unnecessary, as they are generally prepared extemporaneously according to special formulae. A nutritive enema might be added.

Extracts and Liquid Extracts.—The rationale of the processes for solid and liquid extracts of cascara was criticised. Taking the preparations as a class considerable improvement in the way of shortened processes is necessary. The "one in one" liquid extract was condemned, a fifty per cent. liquid extract being preferable.

Glycerina.—Several additions may usefully be made.

Medicated Wool and Gauses.—The official recognition of these as antiseptic dressings, impregnated with salicylic acid, iodous form, sal alembroth, etc., was recommended.

Granules and PILules.—Preparations of aconitine, digitaleine (crystallised), and strophanthine might be introduced in these forms, similarly to the Codex. Samples were shown by Mr. Martindale which had been made in an ordinary pill machine. They weighed 2/3 grain, contained 1,10 milligrammes aconitine, and were made up with sugar of milk and coloured with carmine.

Infusions.—Three-fourths of these are very seldom used, and a general direction might be given similar to that given for decoctions.
Infus. Cinchona Acidum.—Specially should be deleted. Concentrated infusions were condemned, as well as cold water infusions.

Iodoform should be in crystals, and coumarin should be used to aromatise it.

Lamelle.—Of doubtful utility with a gelatin basis.

Hypodermic Injections.—All alkaloidal solutions should be preserved with salicylic acid, similarly to the official solution of hydrochlorate of cocaine.

Liquors.—A soapy solution of cresol might be added.

Liquor Hydrargyri Perchloridi should have the chloride of ammonium omitted.

Lotions.—Additions in the shape of lotions of boric and carbolic acids, and perchloride of mercury should be made.

Mixture.—Mista Croceti should be diluted.

Oils.—The use of the term "Otto" is recommended for all essential oils to avoid confusion with fixed oils. The proposed substitution of sesame and cotton seed oils for olive oil was deprecated.

Paraffins.—The use of a mixture of hard and soft paraffins was recommended for an ointment base which would not completely liquefy under 113° F.

Pepsin.—Should be freer from peptone than the present preparation, and of greater digestive power.

Passarius.—It is proposed to introduce a gelatin basis for these.

Pills.—The formulae should be modified for several.

Powders.—Several of these might well be added.

Soap.—As a class should be exactly defined.

Spirits.—An official preparation corresponding to Rubini's preparation might be included, and some at present official deleted.

Succi.— Might be extended.

Suppositories.—It is recommended that the curd soap basis be discarded, and the cacao butter used in its place; also in such a case as morphine, other strengths than a standard suppository could become official by stating that more or less medicament could be used if needed.

Syrups need simplifying in some cases. The water should always be boiled before using it for the syrup.

Tablets, Compressed.—The introduction of these was noticed but not recommended.

Tablets with Chocolate are recommended for nitroglycerin, cocaine, and menthol.

Tablets for hypodermic injection.—It is said that the use of a basis consisting of a mixture of acid or acid salt (such as cream of tartar) and an alkaline carbonate greatly aids the solution, which is often otherwise slow.

Tinctures need decimating, and in some cases standardising. In some cases the strength might be increased. Maceration and percolation admit of uniform results, but special methods of procedure are necessary.

Lozenges.—The introduction of black and red currant basis is recommended.

Ointments.—Some could be modified considerably.

Inhalations.—Doubtful if they should be included.

If admitted they should be considerably increased and altered.

Wines.—Sherry is probably the best for most purposes as the vehicle. The present process for vinum ferrri should be retained. A sweet Malaga wine suitable for children should be introduced.

Mr. Parker, President of the Association, in opening the discussion, was of opinion that percentage solutions should all be made so that one grain of the medicament was contained in 100 minims of the finished product, believing that to be the intention of the prescriber. With regard to suppositories, he was not in favour of giving particulars directing that more or less of the medicament could be used if required. He would rather have one morphine suppository of a definite strength, so that no misunderstanding could occur if only the term morphine suppository were used. He was not in favour of allowing two qualities of drugs to be introduced, as for instance both the natural and artificial salicylic acid, and chloroform and ether prepared from pure and methylated spirit.

Mr. J. C. Hyslop, in the course of his remarks, characterised the pills and ointments of the Pharmacopoeia as a disgrace to pharmacy, and alluded to the variability met with in various trade samples of pills.

Mr. Davies, who followed, objected to the introduction of tablets into the Pharmacopoeia, and gave some particulars of the method adopted at King's College Hospital for ointment making, in which the finished product was rubbed through a sieve, and ensured a perfect product.

Mr. C. B. Allen, in alluding to the question of the introduction of the metric system of weights and measures, was of opinion that even if that were done the old system would have to be kept on, so that the two would work side by side. He advocated the use of a glyco-gelatin basis for the manufacture of pastilles, and their official recognition. He did not wish to see the Pharmacopoeia become a compendium of general information, as some seemed to be inclined to make it.

Mr. Gulliver was in favour of more complete tests to each article in the Pharmacopoeia, so that no difficulty would be experienced by the pharmacist in ascertaining the purity of his drugs.

Mr. Pickard alluded to the bad condition in which the iodide of iron was usually sent out, and said that 10 per cent. of reduced iron should always be added to it, if a fairly stable preparation were required.

Others who took part in the discussion were Messrs. Cracknell and Taplin.

Mr. Martindale, in his reply, laid stress upon the fact that if the metric system be adopted at all it will have to be the only system. It cannot exist side by side with our present system. He was of opinion that it would probably be adopted in the next Pharmacopoeia, as the Royal College of Physicians, amongst others, was in favour of it.

After Mr. Taylor had proposed and Mr. Andrews seconded a vote of thanks to Mr. Martindale, the meeting terminated.
A meeting was held on Thursday, March 14, Mr. H. T. Durant, Vice-President, in the chair. A paper on Argon, the new constituent of the air, was read by Mr. A. M. Peter, who summarised the investigations which had been carried out, and the facts which had been ascertained regarding this body.

Mr. J. R. Walker then relieved Mr. Durant in the chair, and the Reporter on Pharmacy gave his report as follows:

REPORT ON PHARMACY.

BY WM. MOORE.

In taking a retrospect of the Pharmacy of 1894, one is impressed by the progress that animal preparations have made in every-day pharmacy, and, secondly, by the army of synthetic products which are forced upon us, have an ephemeral fame, and are forgotten. Pharmacy is indeed suffering from an epidemic of new remedies.

Animal extracts.—Thyroid extract does seem to deserve much of the credit it has gained, both with the medical profession and the public. The most attractive form in which it is supplied is compressed tablets. There are many objections to these. They are generally the dried and powdered glands, compressed and sometimes coated, are naturally hygroscopic, contain unaltered animal matter, and are therefore very prone to putrefaction. When the remedy is demanded in a solid state, the least objectionable is found to be the dried precipitated extract, devised by Mr. Edmund White, who published his process in the "Pharmaceutical Journal" (3rd ser., vol. xxiii., p. 65). This powder is non-hygroscopic, perfectly stable, and may be dispensed in powders or cachets. Up-to-date pharmacists are now stocking the antitoxins of tetanus and diphtheria, since they are acknowledged to be of value, whilst many others, such as testicular extract and supra-renal capsule extract, remain at the probationary stage.

Synthetic bodies.—Of the new synthetic bodies those intended for use as hypnotics are by far the most numerous, although as yet it seems that the perfect one has still to be discovered. Many of them are of proprietary origin, so that it would be invidious to expressly mention them, others are old friends refurbished and reintroduced under new names, or differing only in unimportant particulars. To this latter class belong such compounds as bromal hydrate and bromoform, which have no particular advantages over their chlorine analogues. Chloralose and chloral-oxide are effectual in smaller doses than ordinary chloral hydrate, but have no further advantages.

Aluminium compounds.—The claims of aluminium compounds for use as astringents and antisepsics seem to be scantily recognised; they may be used as powders for dusting, or in solution. A selected few may be given as examples, such as alumonal (aluminium naphthol sulphonate), salamin (aluminium salicylate), tannal, boro-tannal or outol (aluminium boro-tannate).

Antiseptics.—Tablets of mercurio chloride mixed with bicarbonate of sodium and tartaric acid and coloured, are now largely used for extemporising antiseptic solutions. Unfortunately there is great want of uniformity in the colour, size, and strength of the products of different manufacturers, whilst the carelessness with which they are distributed is beyond comprehension. I have seen an ordinary one-pound white wood-top corked bottle, such as is ordinarily used for lozenges, filled with them, having merely a name on a written label and a small "poison" slip attached. They were of such colour and size that they could not be distinguished from lavender lozenges at a yard distance. They are official in the new supplement to the German Pharmacopoeia just published, as is also another antiseptic which is coming much to the fore, solution of formic aldehyde (95 per cent.), known in this country under the proprietary name formalin.

Compressed Potassium Permanganate.—Another form of compressed medicament capable of abuse is that of potassium permanganate. It is to be hoped that the enterprising manufacturers who introduced the tablets never intended them for other use than as disinfectants. Whilst admitting the general utility of compressions, their indiscriminate use is to be deplored, and it is questionable whether their introduction can have been upon the whole of benefit either to pharmacy or the public.

Glycoo phosphaes and Ferratis.—Physiological data are being largely taken into account in selecting remedies which are intended to become readily absorbed in the system. The glyco-phosphates come under this category; they are prepared artificially in a perfectly pure condition. They are regarded as a most suitable source of assimilable phosphorus, since glyco-phosphoric acid is a decomposition product of lecithin, resulting from the decomposition of nerve tissue. Ferratis is another product of this type. It is described as an albuminate of iron, obtained from liver, but the process is not made public. Its claims to recognition are that it causes no irritation in the stomach, and does not affect the teeth, the inference being that it is an absolutely inert substance which passes through the system unchanged.

Standardisation.—The researches of Paul and Cowalay upon Ipecacuanha, recently published, conclusively show that it is possible to standardise the drug for alkaloid value, but that titration alone would be insufficient if the second alkaloid should prove to be inert and require to be separated. It is shown to be possible to standardise eucalyptus oil for eucalyptol, by the process patented for manufacturing purposes by Faulding, which consists in adding syrropy phosphoric acid to the oil at a low temperature, when a compound of phosphoric acid and eucalyptol crystallises. This compound is decomposed by water and distilled.
simple piece of apparatus devised by Mr. Blison, a Bournemouth pharmacist, can be used to turn out medicated glycerin pastilles in a few minutes. It is only necessary to keep a stock mass of glyce-gelatin in readiness; a formula used by the inventor consisting of one part gelatin, two and a half parts each of glycerin and water. The introduction of cachets naturally caught the popular fancy, but being regarded by the average pharmacist as an innovation, they have not been pushed by him to the extent which they deserve. Equipped with a simple machine like the Morstadt apparatus, there is no reason why they should not be dispensed at the same price as powders, as their preparation undoubtedly requires less time. A machine supplied by Messrs. Christy and Co. is capable of filling three sizes at once.

The report gave rise to a discussion, in which the Chairman, Messrs. Aubrey Hill, Davis, Tunbridge, Tickle, Gayer, Jealous, and the Secretary took part.

The meeting then adjourned.

ROYAL INSTITUTION.

THE RARE METALS AND THEIR ALLOYS.

The lecture delivered by Professor Robert Austen at the Royal Institution, on March 15, was devoted mainly to a description of the effects produced by the presence of rare metals in traces, on the properties of the "base" metals, and vice versa.

Professor Austen's experience as chemist at the Mint, and Professor of Metallurgy at the Royal School of Mines, enables him to speak with authority on the most recent modifications of alloys, and imparts additional interest to his remarks. The incident of the little tin soldiers of 'Hans Andersen's' Fairy Tales was used at the commencement to illustrate the effect of heat upon alloys, and in tracing the points of resemblance between men and metals allusion was made to the similarity of terms used to describe pre-eminent qualities in both. Thus there is a class of "noble" metals, as well as a large number which by themselves can serve no useful purpose, but have to be associated with one another in various ways before useful products can be obtained. The alchemists regarded the metals as bodies having volition of their own, the "noble" metals being such as resist the fire, as noble natures among mankind resist temptation, and the microscope, which has done so much for the biologist, is now largely instrumental in studying the effects of environment and minute traces of foreign matters on the morphology of metals. The "rare" metal of the metallurgist is not necessarily considered rare by the chemist, for the latter called those which are only found in small quantity rare, while the former reserved the term for difficulty reducible metals.

Among the rare metals of the metallurgist may be considered those which occur in the free state, such as gold and the metals of the platinum group, and those which occur in combination, generally as oxide, such as chromium, manganese, titanium, uranium, zirconium, molybdenum, and tungsten, and one might add nickel and cobalt. Carbon has no effect in reducing the compounds of these metals under ordinary condi-

tions, but aluminium possesses deoxidizing properties to a peculiar extent, and may be described as "greedy" for oxygen. Although it may be heated strongly in air or oxygen without more than a superficial oxidation, it will still remove oxygen from the oxides of many metals, notably in the case of chromium. In the case of the rarer metals, the action goes on without violence, but when the baser oxides are treated, reduction occurs with great energy and sometimes with explosion, as when aluminium is heated with lead oxide.

In the course of these preliminary remarks two experiments were made which strikingly illustrated how metals in the state of oxide differ in resisting reduction to the metallic state. In the first, when oxide of chromium was fused with finely divided aluminium, the chromium was found to give up its oxygen to the aluminium with the greatest difficulty, the temperature indicated by the pyrometer being 2500°. In the second instance oxide of lead was fused with the aluminium. Here the oxide was so easily reduced that an explosion, more or less violent, occurred in the furnace used for the purpose.

The combustible properties of titanium were illustrated in a striking manner. It burns with great brilliancy in air and in nitrogen, and resembles vanadium in the fact that both are reduced with extreme difficulty, a continuous heat of three to four hours and the association of an electric current being necessary before it can be isolated. After alluding to the fact that the rarer metals cannot be obtained without the association of a small percentage of carbon, carbides being thereby formed, Professor Robert Austen paid tribute to the invaluable researches of Moissan, on the isolation of the rarer metals.

The electric-arc furnace, by which so much work had recently been accomplished in the reduction of the rare metals with the acid of carbon, was primarily due to Siemens, but has been brought to its present state by Moissan, from whom a number of specimens of rare metals, such as have never before been exhibited, had that day been received. By means of Moissan's furnace, in which an electromotive force of from 800 to 1000 volts was used, and a temperature of 3000° C. was attained, chromium, whose melting point largely exceeds that of platinum, had been reduced and fused, and although the electric arc usually produced carbides instead of the absolutely pure metals, its value was still enormous. As a matter of fact, we know little of the rare metals except in combination with carbon. Even iron and steel are unknown to the metallurgist except as containing carbon as an essential constituent, and Moissan has obtained diamonds by heating carbide of iron in the electric arc, and cooling it in water, or better, in molten lead.

The principal value of the rare metals lies mainly in the effect which they produce when present in small quantities in the commoner metals, and similarly the latter have a peculiar effect on their rarer fellow-metals. Thus, the presence of one-fifth of one per cent. of bismuth largely lowers the fusing point of gold, and reduces its strength, while an equal amount of
titanium—a rare metal—raises the fusing point and largely increases the strength.

As yet but little is known of the applications which may be expected from alloys of molybdenum, uranium, and vanadium with steel, but judging from the remarkable results which have been obtained by the introduction of small quantities of chromium, tungsten, and titanium into steel, we may reasonably expect remarkable results from the first three metals when thorough investigations have been carried out in the line of Moissan's experiments. An opinion as to the probable usefulness of a metal in alloys can be formed by comparing the path traced on the temperature chart by a spot of light reflected from molten steel with that caused by steel into which a small percentage of the metal under examination has been introduced. The difference in the latter case is due to the formation of the subordinate curve, caused by the disturbing effect of the new metal. In fact, it is by a similar process that impurities in such metals as gold and silver are ascertained. The position of the subordinate curve in the chart relatively to the principal curve varies, in some cases it is higher, in others, as in an alloy of tin and bismuth, it is below the curve of either metal. It is dependent upon the solidifying point of the constituents. Whenever the subordinate curve is low down the alloy formed is weak, when high up, strong, and from these data conclusions can be drawn as to what part the alloy under examination is likely to play in industry.

This matter might be further illustrated by the effect produced by Palliser steel shot with chilled points and shot of chromium steel on armour plate of various periods. Using 4-inch shot and 6-inch armour plate, it was found that in the case of the ordinary compound steel plates they were penetrated by the chrome steel, but broke the Palliser. Steel plates containing a trace of chromium were still penetrated by the chrome steel, but broke up the Palliser still more. Plates containing 2 per cent. of chromium were less penetrable to the chrome steel projectile, and had a more destructive effect on the Palliser; the chrome steel shot rebounded from a "nickel-steel" plate, while the Palliser was shattered, and, finally, even the chrome steel was broken when striking against the "Harveyed" nickel steel, which is now coming into use, and was employed on the Majestic, whose 14-inch plates are believed to be impenetrable by any projectile known.

Another instance showing the use of the so-called rare metals was illustrated by the Yarrow torpedoboat, which has been made of aluminium alloyed with 4 per cent. of nickel. This yacht is 50 per cent. lighter, and travels three knots faster than a similar one made of steel; and experiments are being made with an alloy of aluminium, with 2 per cent. of titanium, which it is hoped will prove of still greater utility.

Professor Austen next performed some experiments illustrative of the properties of carbide of calcium. This compound is readily decomposed by water, acetylene being formed, with lime water as a bye product. Similarly with carbide of aluminium, but in this case marsh gas is formed instead of acetylene. Moissan's process for the formation of artificial diamonds was described, and a photograph was shown upon the screen illustrative of their appearance. Professor Austen had himself prepared these, and pointed out two which, as far as could be ascertained, were really diamonds.

In conclusion, it was mentioned that England had done more for metallurgy generally than any other country, with practically no endowment, and it was to be regretted that whereas twenty million pounds was expended last year on our Navy, and no less than one million on the Majestic, whose fighting efficiency depended so largely on the results of recent metallurgical research, only about four thousand pounds had been distributed as endowment for scientific research, and only a small proportion of this had reached the metallurgist.

CHEMISTS' ASSISTANTS' ASSOCIATION.
At the meeting held on March 14, a paper was read on—

THE PHARMACIST IN FICTION.

BY A. C. MEYER.

It was pointed out that few characters occur in literature more sparingly than the pharmacist, who is the Rubenium or Vanadium of the mines of fiction. The older workings of English literature yield a few examples of the apothecary, but for good specimens of the modern pharmacist one mainly explores the native deposits. Fortunately, however, the deficiency may be made good to some extent from foreign sources. Even more striking than the rarity of the pharmacist of fiction is the unanimity with which authors have treated him as a being of abnormally low morality or intellect.

No writer of fiction previous to the end of the last century appears to have given an exhaustive character-sketch of the apothecary, although several older authors casually allude to members of the craft. There is one reference, and one only, to a genuine apothecary in Chaucer's 'Canterbury Tales.' It occurs in the "Pardoner's Tale," in which one of the three men who have found a treasure poisons the wine of his comrades. The miscreant obtains the poison under the ever-effective pretence that

... he might his rattis quell.
And eke ther was a polkat in his hawe,
That, as he sayde, his caponus had is alwe.
"Thapotecary" answered:—

And thou shalt have
A thing that, also God my soule save,
In this world ther aye no creature,
That eke or drunk had of this confecure,
Nought but the mountance of a corn of whete,
That he ne schuld his lif anoon for-letto.

Shakespeare's only pharmacist is he of Mantua, whom Romeo bribes to supply the poison of which the sale is a capital crime. Of the apothecary's small part of seven lines, the words,

My poverty, but not my will, consents,
are probably the best known utterance ever placed in the mouth of a member of the pharmaceutical craft.

The apothecary himself is too generally familiar to require quotation. We all remember, too, that after
instilling into the "cattiff wretch's" mind doctrines subversive of social order, such as the famous

The world is not thy friend, nor the world's law, Romeo took care to leave behind a letter giving a clue to the source of his purchase, and we may, therefore, infer that the poor apothecary did not long enjoy the tempter's ducats.

In the pages of Molière, a member of the pharmaceutical craft fills a place in the comedy "M. de Pour-

cesaugnac," as the satellite of a doctor, whose patients he entertains in the waiting-room with stories of his master's marvellous skill. In the famous "Mala
de Imaginaire" we are introduced to Monsieur Fleurant, whose exorbitant bill Argand, the imaginary sufferer, is engaged in checking at the rising of the curtain. Monsieur Fleurant sugars his charges by the most flowery expressions concerning the action of his potions. As thus:

... the same day an hepatic julep, soporific and hypno
tic, prepared to send Monsieur to sleep; 35 sois. ... On the 28th a nice purgative and corrective draught, made up of fresh custard, tisels, with Turkish eunus and other ingredients, according to M. Purgon's prescrip
tion, to expel and evacuate Monsieur's bile, four livres, etc.

The play is concluded by a medico-pharmaceutical ballet, which, is of special interest, because Molière wrote it on the day of his death, February 17, 1673.

The older writers habitually introduce the apothecary as a personal retainer of the physicians. Chaucer, for instance, introduces a doctor of physic who regales his fellow Canterbury pilgrims to a fabliau of his own.

It is stated of this physician that

Full redy hadde he his apotecaries
To sende him drages, and his letties.

In the seventeenth century, however, the apothecaries in England began to usurp functions properly belonging to the medical profession. This fact is responsible for many scurrilous allusions to the craft among our poets and novelists. Thus Dryden (Epistle XIII.) writes:

Th' apothecary-train is wholly blind,
From lies a random recipe they take,
And many depths of one prescription make,
Ungrateful tribe! who like the viper's brood,
From medicine issuing, suck their mother's blood!

while Pope denounces the apothecary playing the doctor's part "bold in the practice of mistaken rules" with his usual vigour.

We are indebted to that prolific author, Captain Marryat, for the creation of Mr. Phineas Cogphagus, the most detailed picture in English fiction of the apothecary of the Georgian Era. Besides Cogphagus, Marryat has drawn for us Mr. Brookes, the gentle but phthisic assistant; Timothy, the errand boy; Japhet himself, who afterwards becomes a full-blown apothecary at Reading; and Mr. Ebenezer Pelligit, the single-window-
shop rival and neighbour of Cogphagus.

An altogether different personage from the dignified Cogphagus, though belonging to the same historical period, is Mr. McGarry, the west of Ireland apothecary in Samuel Lover's story 'Handy Andy.'

It would be unfair to accentuate the contrast between the humour of the characters of Cogphagus and McGarry and the delicate touches with which Thackeray has outlined the pharmaceutical career of the elder Pendennis, from his humble beginning as a small apothecary until his culmination in the ranks of the squirearchy. Thackeray's peculiar vein of cynicism constantly peeps through his references to John Pen
dennis. He pictures the apothecary curing Master Ribstone, the son of Sir Pepin Ribstone, of an indigna
tion; his consequent patronage by Lady Ribstone and society in Bath; his gradual withdrawal from the apothecary business, leaving him "with only a little surgery attended by a genteel young man"; his accre
tion to the ranks of "Gigmanity"; and his final transfor
tion into John Pendennis, Esquire, of Pairoksa, Claverley, who disliked reference to his late surgery as much as Pendennis the surgeon had disliked refer
tion to the bygone drug-shop. We recognise in him at once the man true to life, whose replica we con
cantly encounter. Life-like, too, is the Mr. Thomas Groffen, the tall, thin, yellow-visaged chemist in the "Pickwick Papers." With Groffen we arrive at the reign of the chemist, vice apothecary, deceased. As the "chemist," too, the craftsman Jenner figures in Charles Reade's "Hard Cash."

There is a slight sprinkling of apothecaries in German fiction—mostly in humorous novels and popular comedies, where they are generally held up to popular derision. In Goethe's "Hermann und Dorothea" the apothecary is a selfish, liogacious, and rather close
fisted grumbler.

In 'Apotheker Heinrich,' a novel by Herrmann Heberg, a prominent German author, the characters are almost exclusively medical and pharmaceutical.

The finest pharmaceutical character, from a literary point of view, in the whole realm of fiction is M. Homais, one of the leading personages in Gustave Flaubert's famous novel, 'Madame Bovary.' The grotesquely comic Homais is not a pleasant person. He is as self-seeking, mischievous-making, conceited, and cringing a snob as can be found in French literature, an ardent village politician, and a sham scientist, always airing his scanty stock of rickety chemistry and dog-Latin. He is fond of addressing imaginary audiences concerning his devotion to Pantheism, and his respect for the deity of Socrates, of Franklin, Voltaire, Boisanger. The declaration of the Rights of Man, and quotations from the encyclopedists, loom in his conversation almost as largely as quack chemistry.

Although a contemptible fellow, Homais is a good pharmacist. His head is as full of formulae as a text-
book, not only for medicines, but for jam-boiling, cheese-preserving, and wine-doctoring.

There is another pharmacien in French fiction whose sphere of activity is laid in the same district as that of Homais—namely, the Polish chemist Marowski, in Guy de Maupassant's 'Pierre et Jean,' a broken-down Polish refugee, supposed to have passed through a long career of Nihilistic propogandas.

To Alphonse Daudet, the first living novelist of France, we owe the creation of two pharmaceutical types which will have as lasting a place in literature as Homais. But whereas Homais is the incarnation of the selfish, proscat, crafty bourgeois of the North, the pharmacien Béruquet, and still more so, his assistant Pasclon, are representatives of the almost
sub-tropical South, utterly foreign to northern conceptions. The pair play a prominent part in the three novels recounting the adventures of Tartarin of Tarascon.

In another of Daudet's books, 'Jack,' we make the acquaintance of two ladies who may almost be classed as pharmacists. They are Mme. Rivals, the wife of an old country doctor, and her granddaughter Cecile.

Among British living novelists there is probably not a single one of eminence who has drawn an adequate picture of a pharmacist. A firm of chemists is mentioned in a novel called 'Laura Ruthven's Widowhood,' published a few years ago, but the characters are scarcely of a kind that are likely to find a permanent place in literature.

A chemist named Joseph Blake occurs in a book called 'A Modern Minister,' the author of which has had the sense to remain anonymous.

Considering that about 1600 novels are published in this country every year, it is probable that many pharmaceutical children of fancy are born to blush unseen and pine away on the two-penny heap of the coster's barrow, among forgotten Romanticons and Restoration comedies. Indeed, the pharmacist, or at any rate the chemist, does flourish in odd nooks of literature.

A few examples may suffice:—

As the doctor's steel-grey eye turned upon him, the baronet's cheek blanched. With long accusing finger the physician pointed to a stain, evidently several hours old, upon the baronet's shirt-front. "Ha!" exclaimed the doctor, "what have we here? Chloroform! See, the peculiar deep-blue discoloration which that drug leaves behind!"

In another story the villain poisons a good old man with prussic acid surreptitiously abstracted from one of the carboys standing at the door of the drug store. A third novel introduces a heroine suffering from insomnia, whose only means of procuring sleep consists in taking a nightly dose of 30 gr. of hydrate of brucine; yet another causes a murder to be detected by making one of his characters apply his nose to an innocent-looking bottle, and accidentally "catch a whiff of the strychnine it had contained."

These are the first-fruits of awakening consciousness to the importance of pharmacy as an aid to novel-writing. The pharmacist's ambiguous position between the professional and the trading classes may have rendered him a specially suitable butt for the spleenetic writer. Are not his charges notoriously exorbitant? Eighteenpence for a bottle containing a pennyworth of drugs? Monstrous! Down on the rascal with all the armoury of satire! When an artist like Mr. Whistler declares that he is justified in charging 300 guineas for a sketch which is an afternoon's work because it represents the training of a lifetime, the public applaud the sentiment. When the chemist applies the same principle to an 8-oz. mixture he is dubbed an extortionate cheat. It is all a question of degree.

A few years ago the late R. L. Stevenson urged a friend of his, an English chemist on the Riviera, who had written a novel of which a pharmacist was the hero, to send the manuscript to a London publisher. It was returned with the chilling remark that the public had no interest in chemists, and that therefore the work could not be accepted. That argument appears singularly fatuous. At a time when the cry is all for psychological novels, for studies of character, one would have expected from a publisher a better appreciation of the truth of Goethe's saying, "Dip but into the full human life—wherever you grasp it it is interesting." The few examples from foreign writers show that the pharmacist can be made interesting enough. By virtue of his intimate connection with potent drugs, his association with a science which has achieved some of the greatest triumphs of the century, his relations with his customers, obviously more delicate and human than that of the man who planks down a pound of butter or hands a beetle-trap from the shelf, one seems justified in regarding the chemist as a particularly promising subject for the writer of fiction. In that belief we may wait patiently for the day when the sympathetic hand of a great English writer shall draw for us the modern pharmacist, with his struggles, his troubles, his weaknesses, his many acts of self-sacrifice and kindness of heart, and light up the sketch with that artist's touch that, "in a trice, life's leaden metal into gold transmutes."

And is it too much to hope that the writer may himself spring from the ranks of pharmacy? Were not Ibsen's first dramas conceived in the Swedish chemist's shop where he served his apprenticeship fifty years ago? Was it not in an apothecary's house at Edmonton that the genius of one of the greatest English poets disclosed itself—the genius of Keats, whom the Quarterly Review would have driven back to his pills, his ointment-boxes, and his plasters?

**MANCHESTER PHARMACEUTICAL ASSOCIATION.**

At the meeting held on Wednesday, February 13, Mr. H. Kemp in the chair, the following paper was read:—

**CO-OPERATION IN PLANTS.**

BY GEO. CLAYTON.

Although in some cases it is difficult to distinguish between true parasitism and symbiosis, and to say definitely that the host plant does not get some advantage from the parasite which feeds on its juices, yet innumerable cases are known where the two plants in union mutually benefit each other, and the term applied to such unions would be symbiosis. Symbiosis may then be defined as the associated existence of two or more plants for purposes of nutrition.

Unlike parasites, two symbiotic plants living in union each supplies its partner with material which the partner requires; a "give and take" or reciprocity system being the rule of their combined existence. Many of the forest trees, common shrubs, etc., have attached to their roots fungoid partners which, absorbing from the ground moisture and mineral matters, hand these chemicals over to the larger tree, receiving in return starch and other organic chemicals which the tree formed in its foliage.
The common black poplar, and many other plants, have woven over their roots the thread-like filaments of fungi.

In the first instance, the root which descends from the germinating seed into the ground becomes entangled with the myceloid filaments of the fungus already existing in the soil, thenceforward the connection continues until death. As the root grows onward the mycelium which invests it grows with it, accompanying it whatever direction the root may take.

Great difficulty is often experienced in rearing various species of rhododendron, broom heath, and many other plants, also in transplanting the same. This difficulty is now accounted for by the rhododendron (for instance) being unable to find its symbiotic partner in some soils in which it is transplanted. The transplanted rhododendron therefore perishes on account of its being unable to assimilate the necessary materials from the soil.

Also, when the attempt is made to rear seedlings of the beech and fir in a good soil destitute of fungus filaments, the seed after germinating and growing a short time perishes, but, if soil or mould recently brought from a wood, or known to contain the living mycelium of the fungus, be placed at the root of the seedling, it at once begins to grow vigorously, owing to its having "connected on" the smaller subterranean partner, which feeds it from the ground.

The number of plants having symbiotic relations of the kind described is very large, most of the Ericaceae, Coniferae, and Cupuliferae co-operating with subterranean partners. It is notable that the chief species of flowering plants which are symbiotic are gregarious in character, and like the oak, fir, heather, etc., form large forests, or moors, and one may be filled with wonder at the magnitude of the immense colonies of subterranean fungi which must exist interlacing themselves at the roots of such forests of trees.

It will also be plain why there is such a profusion of fungi of all kinds in forests and round the roots of certain trees. The lichen is now almost generally admitted to be of a composite character, each lichen being comprised of (1) a fungus made up of a web of myceloid threads with (2) an alga in its interior the combination of alga and fungus thus forming the one lichen plant.

The myceloid threads of the fungus being most exterior fulfill the function of gathering from the air moisture, whilst its partner, the alge, owing to its having chlorophyll, manufactures starch and other chemicals; thus here, again, the partners supply each other with matter necessary for the life of both.

A most interesting proof of this union is afforded by the fact that a lichen may be actually synthesised by sowing certain algae along with certain definite fungi in a favourable place, when the two separate plants amalgamate and interweave their cells, with the result that a lichen is formed.

The co-operation of certain animals or insects with plants is most interesting, the relations between the yucca plant and yucca moth, the fig tree and fig wasp, being pointed out to show that many insects and plants may be regarded as forming a symbiotic community.

The paper was listened to with much interest by a large number of members and their friends.

Seebiens and Notices of Books.

The scope of this work is well defined by its title, and it is doubtful if anyone desiring to become acquainted with bacteriological technique could have a better guide in book form. The authors have both had practical experience as teachers of bacteriology, and are now engaged at St. Bartholomew's Hospital, where they have been in the habit of giving out slips to the students, with full directions about the work to be done from day to day. These slips having been collected and arranged, the outcome is the present small hand-book. It is divided into lessons and arranged in three parts, the first dealing with general bacteriology, the second with bacteriological analysis, whilst the third is an introduction to bacteriological chemistry, and constitutes an appendix to the two previous parts.

There are sixteen lessons in Part I., the first being devoted to detailed descriptions of the methods of inoculating agar-agar, potato, gelatin, etc., with various forms of bacillus and staphylocooccus, as well as sarsina, aspergillus, and torula. Instructions are also given for studying the action of light, oxygen, and heat on the growth and metabolism of bacteria. In the next lesson several of the types are further studied and instructions given for staining them with simple basic aniline dyes — fuchsin, gentian-violet, and methylene-blue. Hanging drop cultures and pus are next examined and stained with Löffler's methylene-blue and by Gram's method. A specific form — Bacillus anthracis — is then taken and studied in considerable detail, occupying the major portion of four lessons. Acid formation, methods of attenuation, asporogenous cultures, impression specimens, examination of fresh tissues, plate culture method, staining of spores, and staining of tissues in frozen sections, all receive attention, and are dealt with in a thoroughly practical fashion. In subsequent lessons the organisms associated with cholera, actinomycosis, typhoid fever, pneumonia, diphtheria, leprosy, tuberculosis, glanders, tetanus, etc., are considered, numerous minor operations being described in the course of the work, and, lastly, attention is directed to phagocytosis and chemolysis.

The second part contains twelve lessons, and detailed instructions are there given for the examination of water, milk, air and dust, soil, decomposing meat, ice creams, antiseptics and disinfectants, animals dead of bacterial disease, and fillets. The ten lessons in Part III. deal with the preparation of metabolic pro-
ducts of micro-organisms, proteoses, bacterial pigments, peptones, albumoses, diphtheria toxin, ferments, enzymes, and ptomaines.

The work is eminently practical throughout, formulae for stains, etc., being given when required, and the manipulative processes being described with great accuracy and minuteness. In properly fitted bacteriological laboratories the book will save an enormous amount of time to teachers and demonstrators, whilst private students provided with suitable material will find all the instruction they require, after they have once mastered the essential preliminaries. To pharmacists and medical practitioners in particular a most useful practical guide is thus afforded, the purchase of various expensive treatises will be obviated, and now the time employed in consulting them more profitably utilised. The authors are to be congratulated on producing a thoroughly satisfactory hand-book, in which the voluminous practical details are concisely and conveniently arranged.

The author of this hand-book is to be congratulated on having produced a thoroughly sound, reliable, and conscientious work which is not written, as are too many books on common complaints, for possible patients, but for medical practitioners. The general public would not be able to understand a single page, whilst medical men would find every page full of information and reliable guidance. The first chapter might perhaps have been omitted without disadvantage as it deals with the physiology of digestion, and though clear enough, carries the subject not further than does any good text-book of physiology. The remainder of the work bears the impress of careful individual labour, and constitutes a really valuable addition to medical literature. The scope of the work will be best explained in the author's words: “Until quite recently it was considered sufficient to make a diagnosis of indigestion, and the practitioner, when he had done this, and excluded cancer, ulcer, acute gastritis, and perhaps, if he were a very able man, stricture of the pylorus, flattered himself that he had done all that was expected of him for his patient. He then proceeded to prescribe for a condition, of the exact nature of which he was profoundly ignorant. He was perfectly right. The most that could be done with the small amount of definite knowledge which was the common property of the profession, was to divide cases of chronic dyspepsia into two groups—those which were accompanied with gastritis, and those which were not. The former he termed ‘irritative’ and the latter ‘atonic’ dyspepsia. But the work of the last few years and the discovery of improved methods have placed our knowledge of the different affections of the stomach upon such a footing that no one has now any more right to make a diagnosis of indigestion, and end there, than he would have to make one of dropsy or cough.” In keeping with this statement we find that not only are the ordinary clinical features fully and clearly set forth, but the methods of chemical examination of materials obtained from the stomach, either naturally by vomiting or by the use of the stomach-tube, and the chemical examination of the urine are explained in the clearest and most practical manner.

At the end of the book a series of illustrative cases is given for the reader to practise himself in diagnosis. This is a most useful feature in the work. The print and general appearance of the book leave nothing to be desired.

THE ILLUSTRATED HINDU MEDICINAL PLANTS. By PURNA CHANDRA SAHA. (Calcutta, 1894.)

The author of this work was formerly Curator of the Hugli (Hooghly) Botanic Gardens, and is at present Lecturer to the Gossopore Practical Institution of Horti., Flori., and Agri-culture. He accompanied Dr. Geo. Watt in many of his botanical excursions, and should, therefore, be tolerably well acquainted with the native medicinal plants of India. His ideas in publishing the work seems to have been to produce an illustrated work, readable both by Hindus and Europeans, concerning the medicinal plants of India, especially those mentioned in the Ayurveda. He hopes to finish the work in five parts if it is well received by the public. The first part occupies about forty pages, and ten of these are illustrated with drawings of the plants, which, with one coloured drawing as a frontispiece, illustrate forty-one species. The drawings are extremely well done, giving an excellent idea of the plants represented. Each one is accompanied by a description in English as well as in Sanscrit, and the synonyms in Sanscrit, Bengali, Hindi, Tamil, and Teligoo are given in their English equivalent sounds. The descriptions of the plants are given in simple language, and there is no lack of clearness in the statements concerning the uses of the different parts of the plants. Thus, under Indian beal it is stated that the unripe fruit is a powerful astringent, and is used in dysentery; whilst the ripe fruit is serviceable in habitual constiveness.

The work is evidently printed by native workmen, and we might guess it to be corrected by a native reader, for the mistakes in English spelling are numerous, and the punctuation not all that could be desired; yet in no case is the meaning obscure. The classification is probably founded on an alphabetical arrangement of the Hindu names, and will be useless to Europeans until the index is published, as the plants of the same natural order are not even placed in sequence; for instance, an arctocarpous and an apocynaceous plant intervene between two solanaceous species. Nevertheless, if the index is carefully prepared the work cannot fail to be useful to both natives and Europeans, and, indeed, so far as illustrations of Indian medicinal plants go, the writer knows of no work that can answer the same purpose in the same way. It will be worth the while of all merchants and medical men interested in Indian medicinal plants to obtain a copy of it, and to excuse the spelling on account of the practical value of the information contained in it and the truthfulness of the illustrations.
Correspondence.

The Major Examination.

Sirs,—I think the suggestions of "M.F.C.S." and "An Associate in Business" excellent. I am one of those "Minor men" who would gladly avail themselves of such a scheme. After a year's preparation at evening classes, with private study, I have, for six months, been compelled to relinquish study. The demands of business and cessation of the only evening classes within my reach have been the combined cause. If the suggestion of "M.F.C.S." had been in force my year's study would have gone far to prepare me thoroughly in one subject at least. Then the compulsory break in my studies would not have seemed to me so disastrous. I detest cram, and when I started work for the Major I was prepared to spend two or three years in continuous study. I could not foresee the circumstances of the last six months. I might add that when I passed the Minor in 1877 it was simply impossible to proceed to the Major. I had spent all I possessed and more. I believe there are many men like myself who have never wholly relinquished the dream of passing the Major. I also believe that they are the men who have a real interest in the scientific aspect of our profession, and scorn the mere passing of an examination by a system of cram.

Another Associate in Business.

Should Doctors Dispense?

Sirs,—I have not read the letters of your correspondents on this subject, but my attention was called to a communication made by Mr. Charles E. Whittaker; whose remarks are by no means novel, in fact, I think he entertains an opinion that is shared by a great number of people, viz., that doctors are even more fitted to dispense medicines than chemists. The people that harbour this idea are by no means very competent judges. There are a great many doctors and chemists who know exactly how this matter stands, but for some reason or another they refrain from giving us the benefit of their knowledge. The class of men I more particularly refer to are those that have satisfied the requirements of both medical and chemists' Examining Boards. Some three years ago I underwent the ordeal that is required by the conjoint board for England and Wales. To compare the pharmaceutical portion of this examination with the Minor, much less the Major, would be absurd to a degree. To allow the young men who have only fulfilled the requirements of this board (viz., devoting a portion of three months to master all the details contained in Proctor, Maisch, and Pereira) to enter into business and compete with the chemist who has devoted his life to the work and passed much more stringent examinations is not only unfair, but is bordering on the ridiculous. Besides all this, for many reasons it is manifestly obvious to most people that the dispenser of medicines should not have the power to write the death certificate, considering the vastness of the fields in both medicine and surgery proper. I think the medical man who has the interest of his patients at heart will find little or no time to tinker and quack in pharmacy when the work can be properly and effectually carried out by the men who have made this branch their special study. As to the knowledge of botany your correspondent dilates upon, I may inform him that he is also wrong on this point, as there is no such knowledge required of medical students.

Glycerin of the Market.

Sir,—In an article on "Glycerin of the Market," by J. L. Tegarden, re-published in your issue of the 10th inst. (page 801), there is a reference to me which so curiously misrepresents my opinions that I shall be obliged if you will afford me space to correct the statement made. On page 802 Mr. Tegarden says, "It has been stated by good authority that distilled glycerin would not be contaminated with arsenic. A. H. Allen, in discussing the subject in the British Pharmaceutical Conference at Leeds in 1892, seemed to entertain some doubts about it, yet in his concluding remarks he distinctly states that it can be removed by distillation."

On looking up the report of the discussion to refresh my memory as to what I really did say, I find that the Conference met at Leeds in 1890, not 1892. Secondly, I did not take any part at all in the discussion at Leeds. I did speak in 1893 at Newcastle, and from the report (Pharm. Journal [8], xx, 278-279) it is quite clear that I distinguished between glycerin resulting from the saponification of fats by superheated steam, with or without the addition of lime, and glycerin recovered from spent liquors. These liquors were commonly neutralised by arsenical acid, and the glycerin was liable to be contaminated with arsenic. On the other hand, no acid was employed in the steam process, and hence an arsenic-free glycerin was produced. I "did not think distillation would remove any arsenious acid previously existing in the glycerin." I "was rather under the impression that the arsenic would go over with the glycerin if it were once in it." How, from these and similar observations, Mr. Tegarden got the idea that I distinctly stated that arsenic could be removed from glycerin by distillation is a mystery which he may be able to explain. I cannot.

Sheffield.

Alfred H. Allen.

Pharmacology and Therapeutics.

Sirs,—There is a fact occasionally observed in the pharmaceutical laboratory, which I think is confirmatory of the soundness of the position you have taken up in the article in your last issue. Pharmacologists state that nitrite of ethyl and nitrite of amyl have the same physiological action, differing only in degree, yet inhalation of the vapour of the former causes blanching of the face and a depressed pulse; while the vapour of the latter produces flushing of the face and a bounding pulse. These phenomena may be due to the same pharmacological action, but one of the effects is evidently very different.

Edinburgh.

D. B. Dott.

Answers to Correspondents.

G. Roberts.—You will probably find Quain's 'Dictionary of Medicine' (Longmans, Green, and Co.) the most satisfactory reference book on the subject.

J. B. Barnes.—Thanks for your expression of opinion, which will be borne in mind.

F. D. Fisher.—Your letter will be forwarded to the reviewer.

Corrections.—Mr. J. C. Umney requests us to make the following additional to his remarks published in last week's Journal: On page 806, column 2, line 8, for "and" read "the extract of which"; and on page 807, column 2, line 26, before "B. betulina" insert "oils of".

Communications received from Macara, Allen, Barnes, Blackburn, Braysby, Dott, Fisher, Goldby, Hill, Jones, McBain, Merck, Mitchell, Wyles.
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS. 833

“THE MONTH.”

Sulphides of Zinc.

A. Villiers shows that precipitated zinc sulphide may be obtained in two varieties possessing the same composition. Each of them may exist in different degrees of hydration, but they are completely distinct, and cannot be directly transformed into each other between zero and 100°. The acid sulphide is obtained in an amorphous form by the action of hydrogen sulphide upon an alkaline solution of sodium zincate. By the action of heat the precipitate appears to assume a crystalline form, but this point is not quite clear, though there is undoubtedly some modification effected. The solubility of both forms of the acid sulphide in aqueous hydrochloric acid is distinguished it from the basic sulphide, which may exist in both amorphous and crystalline conditions, and is precipitated from an acid solution of a zinc salt by hydrogen sulphide. The crystalline variety, which is completely insoluble in aqueous hydrogen sulphide solution, is usually precipitated from a solution of zinc sulphate, and the amorphous, which is but slightly soluble, from the acetate. This second form can be transformed into the crystalline variety by the action of heat (Comp. rend., cxx., 498).

Tropines.

A number of acid esters of tropine and aminotropine have been prepared. Acetyl-tropine, $\text{C}_6\text{H}_4\text{NO-CO-CH}_3$, is a syrupy fluid, obtained by boiling tropine in acetic anhydride, adding ammonia, and shaking with chloroform. It boils at 230°-237° without decomposition, and is soluble in water, alcohol, or ether. The gold salt melts at 193°. Lactyl-tropine, $\text{C}_6\text{H}_4\text{NO-CO-CH}(_2)\text{OH}$, occurs on acting on tropine with lactic acid or ester, and forms white concentric bundles of crystals which melt at 74°-75°, and are readily soluble in water, alcohol, ether, chloroform, etc. It produces no mydriatic effect, but is said to exercise a beneficial influence on the heart's action. The hydrochloride, hydriodate, nitrate, sulphate, and gold salt (m.p. 143°-146°) have been prepared. Succinyl-tropine, ($\text{C}_6\text{H}_4\text{NO-CO-CH}_3$) is obtained by repeated evaporation of tropine succinate with diluted hydrochloric acid, or by the action of succinic chloride or anhydride on tropine. The hydrobromide and gold salt have been obtained in this case, as well as in those of Maleyl-tropine, Tartar-tropine, and Hydrobromyl-tropine. Meta-Malely-bromotropine, $\text{C}_6\text{H}_4\text{NO-CO-CH}(_2)\text{OH}$, also has been obtained by repeated fusion of tropine para-methyl-amylglycate with diluted hydrochloric acid. It is a syrup which eventually crystallises, and forms a gold salt in needle-clusters (m.p. of crystals 192°-193°) (Bericht, 1894, p. 7).

Scopolamines.

Only one ester of scopoline, i.e., scopoamine, $\text{C}_7\text{H}_11\text{NO}$, the scopo- lines of tropic acid, is known to exist in nature, and that is probably identical with hyoscine. E. Marchionni publishes some observations made during the preparation of various compounds of the same class. Acetyl-scopoline, $\text{C}_6\text{H}_4\text{NO-CO-CH}_3$, occurs in white crystals, which melt at 55° and distill at 250°. It is obtained as a hydrochloride or acetate by the action of acetyl chloroide or acetic anhydride on scopoline. It dissolves in chloroform, ether, and alcohol. The gold salt melts at 195°-197°. Benzoyl-scopoline, $\text{C}_7\text{H}_12\text{NO}_2\text{CO-C}_6\text{H}_5$, is prepared as hydrochloride from benzoyl chloride and scopoline. The crystals melt at 68°-70°, and the hydrochloride, hydrobromide, and picrate, as well as the platinum, gold, and mercury salts have been obtained. Cinnamyl-scopoline, $\text{C}_8\text{H}_{15}\text{NO}_2\text{CO-CH}_3\text{CH}_2\text{CN}_3$, is a colourless syrup, which gradually crystallizes, and is readily soluble in chloroform, rectified spirit, and ether. The hydrobromide and nitrate both form white crystals (Bericht, 1894, p. 15).

Volume of Salts in Solution.

L. de Boisbaudran refers to Charpy's confirmation of the generality of the rule that when aqueous solutions of salts are diluted with water, there is a diminution of the total volume. This is held to prove that the volume occupied by a given weight of a salt is greater in proportion as the solution is more concentrated, assuming that the volume of water is constant. With the exception of certain ammoniacal compounds, all mineral salts show evidence of contraction on solution in water. Thus, Charpy states that ammonium chloride and some other salts of the same base are the only bodies of which the solution is accompanied by an increase in the total volume. Sodium acetate seems to Boisbaudran to form a connecting link in this respect between ammonium chloride and the generality of mineral salts. All the salts he has examined also—except sodium sulphate, $\text{Na}_2\text{SO}_4$—show, at the ordinary temperatures, a contraction of volume on crystallisation from supersaturated solutions—sodium acetate, hyposulphite, mono-sulphide, and carbonate; magnesium sulphate, alums, ammonium nitrate, and silver nitrate. In the case of sodium sulphate, it is difficult to prepare extremely supersaturated solutions, and a slight expansion was always observed on crystallisation (Comp. rend., cxx., 539).

Assay of Formaldehyde Solutions.

Brochet and Cambier show that the addition of formic acid to a solution of hydrochloric acid results in the total decomposition of the salt into formaldehyde, hydrochloric acid, and water, as represented by the following equation:—

$$\text{NH}_2\text{OH}+\text{HCl} = \text{CH}_2\text{O} + \text{H}_2\text{O} + \text{HCl}$$

Under certain conditions tri-oximido-methylene (CH$_2$N-OH)$_3$, a triple polymer of formaldehyde, is formed. It is stated that by employing an excess of a solution of hydroxylamine hydrochlorate of known strength, and subsequently titrating the acid liberated, a good method is afforded of indirectly determining the strength of solutions of formic acid. The end reaction is clearly indicated by means of methyl-orange. Monomethylene hydrochlorate acted upon by formic acid is also shown to be converted into trimethylene-triamine (Comp. rend., cxx., 449).

Formaldehyde and Salts of NH$_3$.

Brochet and Cambier, having proved that formic acid converts monomethylene and hydroxylamine hydrochlorates into trimethylene-triamine hydrochloride and formaldehyde, respectively, show that a similar reaction occurs when it acts upon ammonium chloride. In the cold the solution becomes strongly acid and capable of dissolving calcium phosphate, chalk, etc. Trimethylene-triamine hydrochlorate appears to be first formed, but the final product of the reaction is hexa-methylene-amine, a
They are also very hygroscopic, and when brought in contact with a flame swell up and burn (Journ. de Pharm. [6], I., 301).

Pauline.

The alkaloid pauline is obtained from panco-nuts (graines d'Opoula), the fruit of Pentaclethra macrophylla. It occurs in yellow flakes melting at 126° C., at which temperature it decomposes, is insoluble in ether or chloroform, and can be crystallized from hot water, decomposing immediately, however, and turning green. Warm rectified spirit also affects it, and in alkaline solution it gives a play of colours—brownish red, dark brown, etc. E. Merck gives the formula indicated by analytical data, obtained on investigation of the hydrochloride, as C₉H₁₄N₂O₁₉ + 64H₂O.

The hydrochloride forms white needles (mp. 245°—247°), soluble with some difficulty in cold water. The potassium salt melts with decomposition at 185°, and the picrate crystallises in garnet-coloured prisms, which are sparingly soluble in cold water and decompose about 200° after turning black (Bericht, 1894, p. 11).

This substance is described by E. Quessus. Merck as separating from quassin by solution in ether. When purified, it crystallises from alcohol in white flakes which are moderately soluble in ether and chloroform, sparingly so in alcohol, and not at all in water. The crystals melt at 149°—151°, and the optical rotation amounted to [α]ₖ = 42° 6′. Quassin is distinguished from quassin by its tastelessness, and is probably represented by the formula C₀H₁₂O₂, or C₀H₁₀O₂ (Bericht, 1894, p. 18).

Some New Double Iodides.

A. Moesnier describes some combinations of lead iodoide with organic or other metallic iodides. A double iodoide of lead and ammonium was obtained in fine crystals, of which the formula is represented as 3Pbl₂·4NH₃·1·6H₂O. With the iodides of tetra-methyl-ammonium, tetra-ethyl-ammonium, and phenyl-ammonium, compounds were formed, having the formulae: 3Pbl₂·4(CH₃)₄I; 3Pbl₂·4(C₂H₅)₂I; and 3Pbl₂·4(C₆H₅)₂I, respectively. There are several double iodides of lead and sodium, and a new one obtained has the formula 2NaI·Pbl₂·6H₂O. It occurs in fine clear yellow transparent crystals. Lead and lithium iodide is represented as 2LiPbl₂·4H₂O, whilst the introduction of metals of the alkaline earths gives compounds corresponding to the general formula—2Pbl₂·ML₂·7H₂O (Comp. rend., xxx., 444).

Daturic Acid.

A substance having been doubted in certain quarters, E. Girard adduces evidence to prove that his former communication on the subject (Comp. rend., xxx., 205) was fully justified by the facts of the case. He states the opinions of Tschitschibabin and Wanklyn and Johnstone, working by different methods, have isolated an acid of the same formula, C₂H₂O₃, as that he ascribed to daturic acid which occupies a position between pelmatic and stearic acids, and forms salts with magnesium, lead, copper, barium, and zinc, all of which can be crystallised from alcohol. Neutral sodium daturate decomposes in the presence of water, sodium bistrurate being formed. The acid salt washed with ether yields the neutral salt and free acid, whilst similar results are obtained with the potassium compounds (Comp. rend., xxx., 500).
J. Passy considers that the fixation of perfumes by solid bodies, when diffused in an enclosed space, must be due to a process of solution similar to that by which dyes are fixed in tissue. He argues that, in the same way that crystallised fuchsin is greenish with a metallic lustre, and only manifests its characteristic colour when in solution, so coumarin in the crystalline state does not present its characteristic odour. Presumably, therefore, tissue perfumed by coumarin contain it, as it were, in solution (Comp. rend., cxx., 513).

Coagulation of Albumin.

Coagulable albumoinoid substances are found by Ramosen to become converted into solid masses by simple agitation, whether in acid, neutral, or alkaline solutions, and independently of the presence of oxygen, hydrogen, nitrogen, or carbon dioxide. The coagulation is not due to the generation of heat; for it takes place indifferently at all temperatures, and has even been produced in the case of solutions (ammonium albuminate and casein in lime water) which do not coagulate on boiling. In addition, the coagulum produced differs in composition and properties from that obtained by the action of heat. Fresh serum, when alkaline, is but slightly affected by agitation, but the presence of acids or salts favours coagulation (Archiv. für Physiol. and Journ. de Pharm. [6], I., 326).

C. Margot finds that aluminium, magnesium, cadmium, and zinc possess the property of driving forges and other substances containing much silica, in such a way that neither rubbing nor ordinary washing will remove the marks. Taking advantage of this curious property he has constructed pencils and wheels of aluminium, by means of which designs can be drawn upon glass, and it is understood that mirrors, etc., now being sold in London, which reveal figures and various devices when breathed upon, are prepared in this way. The effect is much the same as when sketches are drawn on glass with French chalk, but more permanent (Arch. Soc. Phys. et Nat. de Genève and Journ. de Pharm. [6], I., 363).

I. F. Kebler (Amer. Journ. Pharm., lxxvii., 141), states that highly adulterated beeswax appears to be common in his district of the United States, some containing as much as 80 p.c. of paraffin. Black earthy matter also is moulded into cakes and cleverly coated with yellow wax, whilst other samples contain chrome yellow, mineral matter, resin, etc. Four specimens recently examined were composed of resin, chrome yellow, yellow ochre, hematite, mineral wax, and a little beeswax. A fifth was composed of about equal parts of mineral wax and beeswax. The analytical data are given in the following table, where No. 1 represents a beeswax of known purity, for comparison:

DECOMPOSITION OF ALCOHOL-REDUCED CHLOROFORM.

BY DAVID BROWN AND D. RAINY BROWN.

Dr. Schacht and Biltz, in a paper published in the Pharm. Journal [3], xxii., p. 1005, say "decomposition cannot be detected in alcohol-reduced chloroform until all the added alcohol has been consumed."

One of us took exception to this statement (Pharm. Journal [3], xxiv., p. 391), and showed that after decomposition had been recognised by zinc iodide and starch, as well as by baryta water, reactions were obtained with 1 in 2000 dichromate solution, and the iodoform test, similar to those produced by alcohol, and those were ascribed to the presence of that substance.

Dr. Schacht has since published another article on the subject in the Berichten der Pharmazeutischen Gesellschaft, October, 1884, in which he defends his position, and says that the reactions obtained were not produced by alcohol, but by two substances—chloric ether and phosgeno-alcohol.

Unfortunately he produces no evidence of the production or the existence of those substances in decomposing alcohol-reduced chloroform. He arrives at his conclusion simply from an examination of the behaviour of bought ethyl chloride, which he does not prove to be free from alcohol, and of chloroformic ether, prepared by adding alcohol to phosgene and to decomposed chloroform, which may also have contained alcohol.

On the ground alone that he has omitted to demonstrate the production of ethyl chloride and chloroformic ether in decomposing alcohol-reduced chloroform, we would be perfectly justified in refusing to accept his statement. There is, however, no necessity for taking up this position; our knowledge of the decomposition products of chloroform being only qualitative, there is no difficulty in imagining that these as well as other substances may be produced. In order to follow up the subject we are willing to suppose they are, and further, that they existed in the chloroform we examined.

Briefly the results on which the objection to their statement was based are these:

1. Decomposed chloroforms which originally contained 0·077 per cent., 0·25 per cent., and two samples each containing 0·66 per cent. of alcohol, were found when mixed with 1/2 volume of 1 in 2000 dichromate solution to bleach it in from 15 to 45 minutes, and the water washings of the chloroform gave an unmistakable iodoform reaction.

2. Nothing abnormal was detected in the odour of the samples until zinc iodide and starch reacted.

3. Silver nitrate solution only gave a faint turbidity, and

4. Ethyl chloride gave no iodoform, neither did it bleach the dichromate solution, even after twenty-four hours' contact.

If Schacht is correct, the following changes should readily be observed in decomposing alcohol-reduced chloroform:

1. A marked difference in the odour of the chloroform, before zinc iodide and starch shows decomposition to have taken place.

2. A quantity of chlorine should be produced at the time zinc iodide and starch begins to react, sufficient to combine with all the added alcohol; and

3. That ethyl chloride and chloroformic ether, in quantities which could be produced by 0·077 per cent. of alcohol in chloroform, give reactions with 1 in 2000 dichromate solution and the iodoform test, identical with those produced by alcohol.

How far these conditions are found to exist will be seen from the following results. Trained noses have not hitherto succeeded in detecting any difference in the odour of decomposing chloroform until zinc iodide and starch reacts. If 0·1474 per cent. of chloroformic ether and 0·2629 per cent. of ethyl chloride are produced from a chloroform containing 0·25 per cent. of alcohol, a product is obtained, which it will be found can be at once condemned because of the presence of foreign odours; the quantities may even be reduced to 1/4 without rendering the task of detection a difficult one.

The decomposition products (represented as chlorine) required to convert 0·25 per cent. of alcohol into ethyl chloride and chloroformic ether, according to Schacht's theory, be 0·192 per cent. =0·776 per cent. AgCl. So soon, therefore, as decomposition is detected by zinc iodide and starch, this quantity of chlorine should be obtained by decomposing the products. We have not, however, succeeded in obtaining anything like this quantity. Ten determinations—four of them made so soon as zinc iodide and starch reacted, and the remainder two days afterwards—gave precipitates of silver chloride, ranging from an unweighable turbidity to 0·29 per cent., proving that sufficient chlorine has not been produced to combine with all the added alcohol.

With regard to ethyl chloride, it has already been stated that it gave negative results after twenty-four hours' contact with 1 in 2000 dichromate solution and the iodoform test. The same sample was retested, and confirmed the previous results. A sample of German make was examined, but as it bleached the dichromate solution in five minutes, and gave an abundant precipitate of iodoform, the presence of alcohol was suspected, and it was found to be present in considerable quantity. After washing ten times with its own volume of water and drying, a product was obtained which did not bleach the dichromate solution after standing with it for forty-eight hours, again proving that the reaction observed was not produced by ethyl chloride.

Schacht and Biltz prepared their chloroformic ether by adding alcohol to phosgene and to decomposing chloroform, and employed the products without any purification. It will be observed, however, that the reverse of this process holds good in the case of decomposing alcohol-reduced chloroform where phosgene and chlorine in small quantities are slowly added to alcohol; any chloroformic ether produced by this process would therefore be decomposed by the alcohol present into carbonic ether and hydrochloric acid thus:

\[ \text{COCIO}_2\text{H}_2 + \text{C}_3\text{H}_5\text{OH} \rightarrow (\text{C}_3\text{H}_5)_2\text{CO}_2 + \text{HCl} \]

Assuming, however, that it does exist in the chloroform, the following experiments prove that it does
not give reactions which can be mistaken for those of alcohol.

A sample of chloroformic ether prepared by ourselves, sp. gr. 1:141 at 15°C, b.p. 93°-95°C, was added to pure chloroform in quantities of 1, 0·5, 0·25, 0·12, 0·06, 0·03 per cent., and tested with 1 in 2000 dichromate solution. The 1 per cent. sample had not bleached the solution in forty-eight hours, but the colour was gone in fifty-six hours; none of the other solutions were bleached in fifty-six hours. Another sample (of German make), which was found to contain alcohol, was washed, dried, and distilled, a product being obtained of sp. gr. 1:140, b.p. 93°-95°C. This, when mixed with chloroform in the same proportions as above, did not bleach the dichromate solutions after forty-eight hours’ contact.

As carbonic ether is a possible product of decomposition, it was also subjected to the tests applied to the two others, the proportions added to pure chloroform being 1, 0·5, 0·25, 0·06 per cent., but none of the dichromate solutions were bleached after forty-eight hours’ contact.

We would point out that all the reactions with decomposing chloroform which led to Schacht and Biltz’s statement being disputed were obtained in from 15 to 45 minutes (these have since been confirmed), and that no reactions took place in forty-eight hours with any of those containing the supposed products of decomposition. Whatever may be the result of his further work on the subject, Dr. Schacht has not proved that ethyl chloride and chloroformic ether are produced in decomposing alcohol-reduced chloroform, neither has he shown that they give reactions similar to those of alcohol.

On the other hand we think we have proved that at the time decomposition is first recognised by zinc chloride and starch, chlorine has not been produced in sufficient quantity to combine with all the added alcohol; and we have further shown that in quantities greater than it is possible for them to exist in decomposing ordinary chloroform, neither chloroformic ether, ethyl chloride, nor carboneic ether give reactions which could be mistaken for those of alcohol.

The extent to which botanical detail should be admitted to a Pharmacopoeia is one which may be the subject of some controversy. I think all will agree, however, that so much at least should be given that the plant or the part of the plant described should be easily recognised by the pharmacist. The identification should in the first instance be based upon macroscopic characters, and these should be set forth in sufficient detail to enable an observer to distinguish the plant with accuracy from the adulterations which either have been or may easily be mixed with it. Detailed directions for the detection and recognition of these adulterations seem hardly necessary provided that sufficient positive characters of the drug are recorded.

Macroscopic characters are, however, in many cases insufficient; in such cases microscopic characters should also be given. It is difficult, for instance, to be certain of the identification of the leaves of Atropa belladonna, or of those of Digitalis purpurea by a description of their external features only. Their internal structure, taken in conjunction with their external features, however, enables recognition to be positive. Belladonna leaves contain in certain of their cells aggregations of minute crystals of calcium oxalate, looking under the microscope almost like grains of sand. These are very distinctive. The leaves of digitalis contain no crystals, but are furnished with curiously shaped hairs, which are very distinctive tests of identity. The peculiarities of the epidermal cells of the leaves of senna and the characters of the hairs upon them are distinguishing marks which might well supplement the description of the form of the leaves. Nor is it only in the case of leaves that such anatomical details are desirable. The bark of the two species of Rhamnus may be mentioned. In that of R. purshiana patches of solenochyms are to be seen plentifully scattered through the tissue; in that of R. frangula there is little or no solenochyms. The root of scammony would be identified with greater certainty by regarding the form of the starch grains which it contains, which are peculiar in shape and characteristic of this plant.

Even description of microscopic features in certain cases fails to ensure identification. The fruits of various plants of the natural order Umbelliferae are very important in medicinal preparations, and their diagnosis from merely verbal description is extremely difficult. The natural order is a large one, and one of its principal marks is the structure of the fruit. This consists of a cremocarp, splitting when ripe into two mericarps, which show peculiar arrangements of ridges on their external surfaces, various shapes of the endospore they contain, and groups of peculiar oil glands or vittae in the capillary walls.

The different genera, though agreeing in general arrangement and structure of the fruit, can only be distinguished from each other by minute details or variations of shape, size, and distribution of these three characteristic structures. So much alike are many of them, that language alone fails to indicate their differences. The ridges must be described by

The BOTANY of the BRITISH PHARMACOPEIA.*

BY J. REYNOLDS GREEN, B.D.

Professor of Botany to the Pharmaceutical Society.

In discussing or criticising the botanical work which is contained in the present edition of the Pharmacopoeia, it is important to remember that there is a very great difference between the state of botanical science to-day and that of ten years ago. Not only has much more accurate historical work been published during the interval, but the whole question of botanical nomenclature has been revised, and many plants used in medicine have now been more satisfactorily referred to appropriate genera.

In the remarks I propose to make upon the botany of the Pharmacopoeia, therefore, I wish at the outset to point out that many of the defects existing in the work are not the results of any careless preparation by the editors of the present edition, though they may fairly be remedied by those responsible for the new one which is pending.

* Reprinted from the British Medical Journal, for March 29.
somewhat vague terms, such as blunt, acute, broad, narrow, etc.; the whole fruit may be called flattened, or roundish, or ovoid; the endosperm described as curved or straight, and so on. But, however such a general description may be worded, many of these fruits would fit in with it, and mere verbal indications of the relations are therefore not sufficient for identification. The description of the dill fruit (Paeonanema gracilessis) is thus given: "Broadly oval, about one-sixth of an inch long, flat, and surrounded by a broad membranous border. It has a brown colour, the membranous border being paler. The half fruits or mericarps are usually distinct in the fruits of commerce. Odour and taste agreeably aromatic." A great many of the umbelliferous fruits would correspond fairly well to such a description. The description of the hemlock fruit is a little more detailed: "About one-eighth of an inch long, broadly ovoid, somewhat compressed laterally, and crowned by the depressed stylopod, dull greenish-grey. As met with in commerce, it consists usually of the separated mericarps, each of which presents five prominent more or less crenated ridges, with the furrows smooth, and without evident vitre. Reduced to powder, and rubbed with solution of potash, it gives out a very strong and disagreeable odour." Anyone attempting to identify a fruit from this description alone would speedily find how vague and indefinite the points are, and how many fruits would fit in with them.

In the case of these fruits it must also be borne in mind that the recognition must not be confined to the few which are used in medicine, but must be so accurate as to ensure that others of the British flora are not confounded with them in practice, many of these being extremely poisonous.

In the case of such structures as these umbelliferous fruits a figure of the particular one under description would be very valuable. The position and shape of the ridges, the characters of the endosperm and of the vitre, could be depicted therein with accuracy, and much space saved in the descriptive text. If a diagram of the whole fruit and of its transverse section were inserted it would occupy but little space. Indeed, this mode of indicating characters might be extended to many other fruits used by pharmacists. It may, of course, be argued that the introduction of figures into a Pharmacopoeia would lead to too great an addition to its volume. The question of space is naturally worth careful consideration, but if the figures were inserted the description need not be so lengthy as under the present conditions, and considerable assistance would be afforded for accurate diagnosis.

On looking carefully through the descriptions of plants and parts of plants which are found in the present volume, one can hardly help noticing a certain looseness or indefiniteness, which might well be avoided in future. The vagueness of the description of the dill fruit has already been noticed; there are many other instances. The fig is described as the dried "fruit" of Ficus carica, and is said to consist of the enlarged hollow succulent receptacle, bearing very numerous seed-like achenes on its inner surface."

If this description is to be taken in a botanical sense it is altogether inaccurate. The structure called the "fruit" is not a botanical fruit at all, but an inflorescence. The true fruits are curiously spoken of as "seed-like achenes." Why seed-like? What sort of seed do they resemble? Structurally none; in appearance few. Seeds include all sorts of forms from a broad bean to a poppy seed. The term "seed-like" is therefore not definite; nor is it necessary, for an achene is a much more constant structure than a seed.

The description of the lettuce, on page 219, is noteworthy: "The flowering herb of Lactuca virosa (Linna); 'Bentl. and Trim. Med. Pl.,' vol. iii., plate 160." Surely, if the Pharmacopoeia is to have a description of the plant at all, this does not meet the case. To identify the plant the unlucky pharmacist must procure a copy of a botanical work not universally accessible—indeed, in many places quite impossible for him to reach.

The same looseness of description is found under the head of onium leaves, page 124. They are said to be "more or less divided in a pinnate manner, the lower leaves decussate and sometimes two feet in length, glabrous, and arising from a smooth stem, which is marked with dark purple spots, by clasping petioles of varying lengths, those of the lower leaves being hollow. Odour strong and very disagreeable, more especially when rubbed with solution of potash." Such a description would apply to almost any of our British Umbelliferae. The only point given which is at all distinctive is the spotting of the stem, and this is very variable, and many stems or parts of stems do not show it. The description of the leaves as "divided in a pinnate manner" is vague and not entirely accurate. The smell has a distinct resemblance to the odour of mice, which should be stated instead of its being called "strong and very disagreeable." A point about onium leaves which is fairly distinctive is that the margins of the young leaflets or segments of the leaves are frequently tinged with white near their points; this is not stated.

The descriptions of certain barns and woods may be similarly criticised. Much that is said of many of them is characteristic of many barns, and might very well be omitted, stress being laid instead on definite peculiarities. In the description of quassia wood on page 341 it is said to be "dense, tough, porous, and of a pale yellowish-white colour." It is a little difficult to see how it can be at once dense and porous; the two things vary inversely; the more porous a wood is the less is its density. Again, the material is said to be "the chips, shavings, or maplings of the wood of Picrasma excelsa," and the first character given for identification is "in billets or logs, varying in length and size, but frequently as thick as a man's thigh, and covered by a dark grey bark."

In the present volume no description is given of the microscopic characters of powdered drugs. When we consider that in the present day most pharmacists purchase many drugs in the condition of powders, it appears desirable that they should be able to identify the powder apart from the drug in the unaltered condition. This can be done only by a microscopic
examination. Many of the constituents of vegetable tissues have a very definite value in this respect; many starches are extremely distinctive; the tissues of seeds are very unlike those of roots, and so on. It is only necessary here to call attention to a few illustrations of this point. Ipomeaunana, when powdered, can be recognized with tolerable certainty by two points—the vascular elements are in the form of perforated tracheids, true vessels being absent; the starch grains are of a peculiar appearance. Jalsipin powder again shows distinctive starch grains, peculiar crystals, and numerous resin-containing cells. The powdered seeds of *Strychnos sax-bronica* would be easily identified by the application of the micro-chemical tests for brucine and strychnine.

Many powders need special investigation, of course, to enable accurate diagnostic tests to be ascertained; for example, rhubarb, liquorice, and gentian powders. A new pharmacopoeia would be much improved by the introduction of the distinctive features which such powders present, and these could without much difficulty be determined.

Within the last ten years much more accurate information has been obtained on the point of the definite micro-chemical tests which various constituents of vegetable tissues respond to. Those which are given in the present Pharmacopoeia are often negative, and some depend on very variable constituents. In the case of many decoctions it is stated that they do or do not give an indigo-blue colour with iodine. This test is of little value as given; it, of course, is only a test for the presence of starch in the drug under discussion. The presence of starch in many roots will depend upon their condition when gathered; the quantity of starch, and therefore the depth of the colour of the decoction, on addition of the iodine, will vary very greatly from time to time. In many cases where this test was said to give a negative result, the reason for applying it is not apparent. The value of the test will depend on its distinguishing the drug under examination from another for which it might be mistaken, which does contain starch. In such a case why should not the two drugs be mentioned as differing in this respect?

Some of the micro-chemical lists given are not only not distinctive, but actually inaccurate. Thus *Cusparia* bark is said not to give an arterial red coloration when the fractured surface is touched with nitric acid. In many cases this treatment does produce a red colour, though perhaps not quite that of arterial blood. Presumably this test is meant to distinguish *Cusparia* bark from that of *Nux vomica*.

An instance of new tests which are quite distinctive is furnished by oubebs. When the tissues of the true oubebs are touched with strong sulphuric acid a scarlet colour is produced in consequence of the presence of the active principle. Other cases of a similar kind will be remembered by many botanists.

The differences between the seeds of the two species of *Sinapis* are not accurately stated. It is said that white mustard seeds are inodorous; so are those of black mustard when quite dry. It should be pointed out that the white mustard seeds should be moistened in order to see whether they give off any distinctive odour.

I have already mentioned that in some cases the nomenclature of the plants is faulty. It is a matter of common knowledge that frequently the same plant has been differently named by different botanists, and it has been necessary to quote more than one appellation. Now that the *Index Kewensis* has been completed no doubt greater accuracy in nomenclature is possible, and in all cases the generally accepted name can be ascertained and used. Though not a very important point, this will no doubt receive, as it deserves, attention.

Meanwhile enough has been said to indicate that in order to render the Pharmacopoeia entirely satisfactory from the botanist’s point of view, steps should be taken for the careful revision of the botanical details it furnishes.

---

**ALOIN.**

**BY CHARLES A. SERRE, B. S.**

“... The different kinds of aloin vary as much from each other as do the alkaloids of cinchona bark.”—‘Squibb’s Ephemeris,’ 1884, 669.

Although the above was written ten years ago, it is equally true to-day, for the U.S. Pharmacopoeia gives no guide as to the kind of aloes which should be employed. Yet by common consent all manufacturers take Barbados or Curacao aloes, owing to lower initial cost. At this point all similarity ends, for the resulting “aloin” vary all the way from purified aloes to fair samples.

The U.S.P. tests are next to useless from the analyst’s point of view, as absence of ash does not denote absence of resin, any more than insolubility in alcohol denotes absence of resin (soluble resin) or mineral salts.

Out of a consumption of at least 20,000 pounds a year, not one twentieth part is used by the pharmacist; most of it being used by wholesale houses for the manufacture of pills, and the necessity of reliable tests is keenly felt. Of this more anon; meanwhile a general idea of its manufacture may not be amiss.

The selected aloes, which should be of a liver colour and clear fracture, are dissolved in water at a temperature not exceeding 40° C. Here it may be observed that some manufacturers use dark-sorted aloes, reserving the better qualities for “selected.” This is objectionable, as dark aloes generally prove to be “burnt aloes,” which are detrimental to yield an ultimate quality.

To resume: To the above solution, water is added until the operator is satisfied that all insoluble resin has been thrown out. No exact quantity can be given, as atmospheric conditions and skill in operation are dependent factors. The whole is allowed to stand, and the bright solution, concentrated in vacuo, set aside in earthenware coolers to crystallize, the mother liquor drawn off; the crystals being pressed and purified by suitable solvents and recrystallisation, then granulated or powdered in accordance with requirements.

The extraction of final traces of resin can only be
effected with the aid of elaborate mechanical and chemical methods, and cannot be accomplished on a small scale. At the present time the writer would simply demonstrate the various qualities, and for this purpose typical samples from American, English and German makers of "aloin" were obtained and are tabulated as follows:

<table>
<thead>
<tr>
<th>A. American</th>
<th>B. American</th>
<th>O. English</th>
<th>D. German</th>
</tr>
</thead>
<tbody>
<tr>
<td>Colour</td>
<td>yellow</td>
<td>Brown</td>
<td>yellow</td>
</tr>
<tr>
<td>Melting point.</td>
<td>110°</td>
<td>140°</td>
<td>146°</td>
</tr>
</tbody>
</table>

(Should be only.)

Resin | 58 p.c. |
Ash | 14 p.c. | 47 p.c. | 13 p.c. |

These figures speak for themselves, but are far from satisfactory from the chemist's point of view, as there are no text-books containing reliable information on a method for determining resin quantitatively and absolutely. The present method is too low, giving negative results in C and D, whereas qualitatively and by colour the grade is apparent.

E. Schmidt's 'Anschriftes Lehrbuch der Pharmaceutischen Chemie' gives 142° to 145° as melting point; he evidently must have obtained samples made by the old open evaporation process. The test employed for resin (such as it is)—the precipitation of an ammonio- alcohol solution with a large volume of ice-water—is evidently too merciful, but the best at command.

The ash in B was white and contained no iron, whereas C and D were mostly iron; for the latter in any case there is no excuse if ordinary care is used; to this I attribute the dullness in colour of C.

A very good method of ascertaining if aloin is absolutely free from resin is by adding 20 c.c. of water in a test-tube to one grain of the finely-powdered sample, shaking and allowing to stand one minute. The solution should be perfectly clear. With the exception of A, not one of the above stood the test. All samples not meeting with the requirement should be looked on as suspicious. Ash, of course, is serious, but can easily be detected. The melting point, by which the solubility is affected, should be insisted upon. Until then "aloin" will always be a question of "mixtures" and "abouta."—Druggists' Circular.

THE PROFESSIONAL SITUATION IN PHARMACY.*

BY ALBERT B. FRESCOTT, M.D., PH.D.

Dean of the School of Pharmacy, University of Michigan.

The pharmacist had never such need of skill as he has at present. Here in the United States, where most of the professions are as free as air, the laws require a man to have a measure of professional skill before he can so much as offer himself as a pharmacist to the public. The pharmacy laws mean something to every person looking to pharmacy as a pursuit. Whatever their imperfections or shortcomings, these laws, in the simple fact of their persistence, in this country as well as in the older countries of civilization, mean a great deal as to the character of pharmacy and the kind of skill important for success in it.

The inherent character of a learned profession is shown by the fact that the state requires men to possess systematic knowledge, that is to say science, before they can take the name of the profession. The special skill of a pursuit is shown to be intellectual skill by the fact that men must study in preparation for state examinations before being licensed for the pursuit. We may say, therefore, that, according to statutes representing public sentiment in this country, it is study that is primary to qualification in pharmacy. And it follows that the professional ability of the pharmacist will increase with the vigour and extent of his studies, and the quality of his means of study, various as these really are. The better and broader the studies, the finer and larger the skill. The more thorough the education, the higher the competence at any given stage of practice in life.

Skill is nourished by studies, and studies are sustained in many ways and want many things: A general education, with the use of language and mathematics and more. Work in colleges and laboratories of pharmacy, with instruction in classes and by lectures. The use of text-books of the science of pharmacy, and published authorities for its practice. The direction of preceptors, and observation with reading in the drug stores. Periodicals, the current and continuous publications of pharmaceutical science, making available the researches of masters and experts in all parts of the world. Personal investigation, the consultation of libraries, fellowship in societies, and communication with other workers. Such as these and more are the resources of pharmaceutical study, and go to nourish that skill which is the professional capital of the pharmacist.

Of this skill it may be said, given a barely sufficient quantity of it to pass a state board and be born into the ranks of pharmaceutical existence, on the lower level of the greatest competing numbers: this much does not constitute capital, but it gives a comfortable opportunity to live and by further study to acquire some of the capital of the profession. Every gain of skill above the lower level is a proportional gain of capital for use.

Mercantile businesses suffer from excess of competition, and the mercantile interests of pharmacy share this disadvantage. Manufacturers complain of over-production and financial depression, and pharmaceutical manufacture is not an exception to this complaint. Young men seeking employment or asking better compensation in all avocations meet with discouraging replies. In this state of affairs pharmacy gives very little promise to the young man who will not equip himself with distinct professional skill. In these times it is the thoroughly trained young pharmacist who is not left unemployed. It is the man who has studied pharmacy as a learned profession who has the best places opened to him to-day. And the thorough-going scientific expert is the one man in pharmacy whose prospects are flattering. Furthermore, the work of every such expert creates a demand for more experts, in the growth of the high grade service that gives advantage over common competition. There is a call for men of thorough training, and as fast as such training is put upon trial the call increases.

POOR LAW DISPENSERS.

Some interest having been shown and correspondence received on the subject of the remuneration and status of dispensers to workhouses and poor law infirmaries, we propose to examine the subject from the public as well as the professional point of view.

The regulations governing the appointment of dispensers to poor law infirmaries and dispensaries, of which there are no less than fifty in London alone, are set out in Arts. 12 and 13 of the Poor Law Board orders on this subject, and are as follows:—

Art. 12.—No person shall be qualified to be appointed a Dispenser unless he shall be a Licentiate of the Apothecaries' Company of London, or shall have been duly registered under the Pharmacy Act, 1868, or some other authority of Law in that behalf.

Art. 13.—The following shall be the duties of a Dispenser:—

No. 1.—To devote his whole time to the service of the Guardians as a Dispenser, and attend at the Dispensary at such hours as the Guardians shall appoint.

No. 2.—To take charge of, and keep carefully and safely, as far as shall be in his power, all drugs, medicines, medical and surgical appliances, and medical stores provided by the Guardians for use in the Dispensary.

No. 3.—To compound and supply all medicines, and supply from the stores under his charge all medical and surgical appliances required by the Medical Officers for use in the discharge of the duties of their office.

No. 4.—To prepare and dispense skilfully and cautiously all prescriptions drawn up and ordered by the Medical Officers, and punctually to supply the medicines when prepared to the persons authorised to receive the same, and, when so required by the prescriptions, to express in writing the proper directions to accompany them.

No. 5.—To keep an account, in a book to be supplied to him by the Guardians, of the drugs, medicines, medicinal and surgical appliances, and medical stores submitted to his charge, and, as nearly as may be, of those consumed or supplied to the paupers, and from time to time to lay the same before the Visiting Committee, and bring under the notice of the Medical Officers or the Visiting Committee the need for further supply of drugs, medicines, and medical and surgical appliances, as and when such need shall occur.

No. 6.—To assist the Medical officers in keeping the Alphabetic Index of the pauper patients attended.

No. 7.—To file all prescriptions supplied to him by or on account of the paupers or by the Medical Officers, and keep them in the Dispensary for not less than twelve months after their date.

No. 8.—To prepare from time to time, as directed by the Committee, an estimate of any medicines, drugs, medical and surgical appliances, and medical stores which may be required, and a statement as nearly as practicable of the quantities thereof used and issued to the paupers or to the Medical Officers since the preceding estimate and statement, and an account of the quantities thereof remaining in store respectively, and submit the same to the Committee for their perusal; to balance the same quarterly, and to submit the same, made up to the last quarter-day prior to the audit, to the Auditor of the District comprising the Union or Parish at that time.

In one of the annual reports of the Local Government Board it is stated: "The position of the dispensers in these institutions is one of great importance, and it has been thought right in view of the responsible duties assigned to them to sanction some increase in their salaries." The amount of this increase we find was that after four years' service the dispensers (who are appointed at a salary of £120 per annum), are to receive a maximum of £140. This cannot be regarded as a proper amount for educated and skilled dispensers to be the utmost they may look forward to, and we think the Local Government Board would be well advised to sanction a maximum of say £200 per annum after ten or twelve years' service, especially as some Boards of Guardians would do this, did the regulations permit.

The work done in many of the large Infirmaries is very considerable, as we recently pointed out in an article on the Kensington Infirmary (ante, p. 361) and it is of public importance that only properly qualified and properly paid dispensers should be employed in all public institutions. It is regrettable to find that this is not always the case. No doubt in some of the smaller unions there is not work for a dispenser to be exclusively employed, but in such cases there are always qualified chemists near, with whom arrangements could be made for the proper discharge of the duties, just as medical officers are appointed to attend daily for a short time to give medical advice. We think a very considerable responsibility will rest upon the local authorities who do not fully comply with the orders of the Poor Law Board should any accidents occur through the ignorance and incompetence of unqualified dispensers of medicine being employed, and would venture to urge upon all such authorities the necessity of providing a reasonable and sufficient salary to secure the services of competent and trustworthy officers, and, of course, that the Local Government Board should sanction the same.
THE ANTITOXIC TREATMENT OF DIPHTHERIA.

Much interesting information concerning the new method of treating diphtheria was brought to light at the last two meetings of the Pathological Society, in the course of a discussion introduced by Dr. Bertram Hunt. Not the least interesting part of the debate concerned the method of examination of horses before they were chosen as the source of the remedy. Dr. Sims Woodhead explained that before any animal was accepted it was examined by a veterinary expert and passed as being free from any recognisable disease. It was further tested with the toxins, first of glanders, and then with that of tuberculosis—Koch's tuberculin. Mallein—the toxin of glanders—had been found to be a certain that for this disease. Two or three animals which, as far as could be ascertained by careful physical examination, appeared to be free from disease, were found to be suffering from the disease in a chronic form by the use of mallein, the diagnosis being confirmed by examination of the lungs after the horses had been killed. When the disease is present injection of mallein under the skin causes a swelling which lasts over twenty-four hours, and a rise of temperature. Tuberculin was less certain than mallein, but tubercle was rare in horses.

Mr. Wm. Robertson explained in detail the method of preparation of horses by repeated injections of toxin and the manner of obtaining serum from them when they had become antitoxic. The extreme care used to prevent the entry of septic organisms into the blood of the animal, both during the preparatory injections and when the antitoxic blood was being drawn off by a canula, will reassure those who might fear that there would be morbid germs, as well as antitoxin, in the curative serum. Ten litres of blood could be taken from a draught-horse without fear of injuring the animal. The term "pseudo-diphtheria bacillus" raised some discussion. Mr. Lennox-Brown objected to the term since it referred to true diphtheria bacillus which had undergone a process of attenuation, and Dr. Sims Woodhead stated that this modification of the tubercle bacillus was characteristic of convalescence, a fact Dr. Hunt explained by the existence of antitoxin in the blood of diphtheria patients, the antitoxin having the effect of destroying the virulence of the bacilli.

In opening the debate, Dr. Hunt referred to two kinds of immunity—an active kind, brought about by the use of a mitigated virus; and a passive, brought about by the transference of immunity. A child recovered from diphtheria because it formed an antitoxin, but by the use of antitoxin prepared by another animal a transferred protection could be conveyed to the child to help it against the attacks of the bacillus, of which the offensive and defensive weapon was the toxalbumin elaborated in the substance of the bacillus. It was probable that the toxin stimulated the cells of the animal to prepare the antitoxin. Dr. W. H. Hume thought that in some points speculation had been carried almost into metaphysical regions. Dr. Kanthack exhibited sections of the lungs of guinea-pigs in which diphtheria bacilli had been injected into the muscles of the thigh. Even the smallest bronchial tubes contained diphtheritic membrane.

THE SIN OF SUBSTITUTION.

The Medical Record, a transatlantic contemporary, has recently published under the above title several communications received in reference to the suggested dishonesty of certain druggists, and expresses the opinion that though the American dispenser is not an untrustworthy man by nature, there seems to be something in the nature of his business, as conducted in different places, that gradually perverts his moral sense of rectitude and slowly leads to the "crime" of which complaint has been made. It is suggested that the druggist does not begin by being dishonest, but that unless he exercises the greatest and most constant care he is led gradually into an easy way of looking at the physician's rights, until by a graduated course of counter-prescribing, playing the doctor, and recommending something of his own as better than that prescribed, his sense of right becomes so blunted that it is no longer difficult for him to replace an expensive drug or one not in stock with a substitute.

With regard to remedies for this state of affairs, our contemporary considers that it is not expedient for physicians to go generally into the drug business, but that in self-defence the druggist must reform. Pressure is to be brought to bear upon him, to cause this reformation, from physicians and through the schools and boards of pharmacy. They, it is proposed, should take the initiative, and devise some stringent way of dealing with those who in disgracing themselves bring discredit upon their calling. "If examples were made of some of the wrongdoers by legal proceedings much substantial good would be accomplished. It would, of course, entail some trouble in obtaining evidence, but the desirable end would more than justify the means."

It is well known in this country that the relations existing between pharmacists and medical practitioners in the United States are not the best possible, and it is obvious that the writer in the Medical Record, in stating his side of the question, probably unconsciously exaggerates, besides omitting causes of offence by his own friends. At any rate, whilst deploiring the existence of the practice of substitution as objectionable and unprofessional, it would be interesting to know if American pharmacists invariably abstain from interfering in an unprofessional manner with the business of pharmacists, and, if not, to what extent they consider themselves justified in so interfering.
A Universal Language.

A correspondent of the British Medical Journal writes in no uncertain terms regarding the proposal that Latin should be readopted as a universal language for medical men. He "thinks the revival of Latin is a cause which would have pleased Cato but not the gods. For medical men, Latin is not only dead but decomposed. Scholarship stops the nose at the putrid remnants of a so-called classical education, which strew the pages of modern medical literature." Amongst such remnants he quotes labia, intended as the plural of labium, gumma as the plural of gumma, fenestrum for fenestra, materia medica intended as a neuter plural, bronchia as a plural of bronchia which is itself plural, pubis for pubes. They include also names of the fourth declension—mentus, processus, fraxis, etc. with a plural in i; and Greek derived nouns in ma treated as feminine and of the first declension.

Other examples include numerous terms used by dermatologists, gynaecologists, etc., whilst memoranda and phenomena are often treated as nouns singular. But for the full bloom of barbarism, the curious inquirer may be referred to the pharmacopoeia of a certain hospital for women, which might have been published as a 'pill to purge melancholy' in scholars." Similar inaccuracies are frequent in French, Italian, and Spanish medical works, whilst German writers on medicine are described as adding to the uncoyness of the Latin style for which their scholars are notorious, a disregard of the elementary decencies of grammar which is all their own. Americans take the palm, however, for the greatest fertility in the production of barbarism, "as might be expected from the superior inventiveness of that ingenious people."

Considerable doubt is thrown upon the idea that Latin ever was the language of medicine as a science, and this "philistine" suggests that a good case might be made out for the disuse of Latin having proved a not unimportant help in the advance of medicine. In any case, it is pointed out that it is impossible, even if it were desirable, to revive the use of the language, and that in this matter "the best thing we can do is to leave the dead to bury their dead."

EVENING MEETING IN EDINBURGH.

At the meeting held in the Pharmaceutical Society's house at Edinburgh, on March 22, the first paper read (see p. 836) was a criticism by Messrs. D. and D. R. Brown of the position taken up by Drs. Schacht and Bizz with reference to the decomposition of alcohol-reduced chloroform. This was followed by an important and exceedingly practical discussion, on somewhat unusual lines, on the proposed Imperial Pharmacopoeia. The novelty consisted in the fact that nearly all those who took part in the discussion had embodied their remarks and criticisms in the form of papers. It seems desirable that all the communications read at the meeting should be published at length, but limitations of space prevent this being done in the present issue of the Journal. A selection has therefore been made, for immediate publication, of those papers that deal with the subject under discussion from a general point of view. The remaining ones, which will be published later, are as follows:—"Note on Chloroform" and "Note on Aloe," by D. Rainy Brown; "Ointments," by Peter Boa; "Infusions," by William Lyon; "Pills," by J. I. Fraser; "Extracts," by William Swan; "Waters," by W. S. Glass; and "Linseed Meal," by Alexander J. Dew. The results of the meeting afford one more valuable illustration of the interest taken by Scottish pharmacists in their chosen profession.

EARLY CLOSING OF SHOPS.

In the Bill to provide for the earlier closing of shops, which has been prepared and introduced into the House of Commons by Sir John Lubbock, Mr. Chamberlain, and others, it is provided in Clause 9 that, in the event of the Bill becoming law, a pharmaceutical chemist or chemist and druggist shall not be liable to any fine for supplying medicines, drugs, or medical appliances, after the hour appointed by an order made under the Act for the closing of shops; but the section shall not be deemed to authorise a pharmaceutical chemist or chemist and druggist to keep open shop after the said hour. The time to be fixed for closing shops may on any one specified day of the week be any hour not earlier than 1 p.m., but on other days shall not be earlier than 6 p.m. The local authority of any district shall have power to make the necessary order on being served with an application in writing, signed by not less than one-third the number of occupiers of shops affected in the district, and the order may only be revoked when more than one-third of such occupiers are opposed to its continuance. The penalties under the proposed Act are a fine not exceeding five shillings for the first conviction, twenty shillings for the second, and five pounds in the case of a third or subsequent conviction. Agents and servants committing offences under the Act will be liable to the same fines as if they were occupiers, and the provisions of the Act are to be enforced by the police authorities. The Bill has been read a second time, and evidence is now being received by a Select Committee of the House of Commons, in connection with it.

THE BOTANY OF THE PHARMACOPOEIA.

An excellent and practical article on this topic is contributed to the British Medical Journal for March 23, by Professor J. Reynolds Graven. Special prominence is given to the inadequate nature of the existing botanical descriptions, and to the advisability of introducing histological characters in the next edition of the Pharmacopoeia. The paper is reproduced at length at page 837.
SCHOOL OF PHARMACY PRIZE EXAMINATION QUESTIONS.
Session 1894-95—Winter Course.

PRACTICAL BOTANY.
Professor Green.
Monday, March 25.—11 a.m. to 2 p.m.
Make microscopic preparations of A and B. In what histological points do they differ? Identify both, and leave a sketch of your preparations with the slides.

What are C, D, and E? Comment briefly on each.

BOTANY.
Professor Green.
Monday, March 25.—3 to 6 p.m.
1. Describe the development of the pollen grains in the flower of a dicotyledonous plant. Mention any abnormalities in the course of such development of which you can give instances.
2. What are plastids? Where do they occur? With what varieties of them are you acquainted? Describe their function in a selected case.
3. What are monocot and polystele stems? Describe the structure of a typical stele.
4. Give some account of the movements of water in a dicotyledonous tree. On what do they depend?
5. Describe the appearance and structure of the sexual generation of the common fern.

CHEMISTRY.
Professor Dunstan.
Tuesday, March 26.—2 to 5 p.m.
1. Distinguish between temperature and quantity of heat. State briefly how you would accurately determine temperatures in the neighbourhood of -180° C. and 1000° C.
2. An iron cylinder at 13° contains oxygen at a pressure of six atmospheres. The cylinder being capable of standing a pressure of twenty-one atmospheres. If heated, at what temperature will it burst?
3. Write an account of the processes of oxidation and reduction. Illustrate your answer by reference to the action of the following substances: Nitric acid, hydriodic acid, chromic acid, hydrogen sulphide, hydrogen peroxide.
4. What is meant by "nascent hydrogen"? Mention some chemical changes in which it is supposed to be concerned.
5. State how the following substances may be prepared: Sulphur trioxide, borax, sodium carbonate, phosphorous acid, and fluorine.
6. Describe how the following compounds could be prepared from mercuric cyanide, viz.: cyanogen, prussic acid, and potassium cyanide. How is the last-named salt prepared commercially, and to what impurities is it subject?

EVENING MEETING IN EDINBURGH.
Friday, March 22, 1895.

MR. J. LAIDLAW EWING IN THE CHAIR.

The third evening meeting in Edinburgh of the present session was held in the Society's Hall, 36, York Place, on Friday, March 22, at 8.30.

The minutes of last meeting having been read and approved, apologies for unavoidable absence were intimated from Messrs. P. Boa, D. Brown, C. F. Henry, G. Lunan, T. Maben, J. Nesbit, and W. Swan.

The first paper read was on the "Decomposition of Alcohol-reduced Chloroform," by D. Brown and D. Rainy Brown. This will be found at page 696.

The meeting then proceeded to a discussion on the proposed imperial pharmacopoeia, when the following communications were read:

SOME RECENT CRITICISMS AND SUGGESTIONS.

BY THOMAS MABEN.

Being pressed to contribute my quota to the discussion on the proposed imperial pharmacopoeia and not being prepared to say anything worth while, in the way of constructive criticism, that has not been as well said by others already, it occurs to me that I might usefully draw your attention to what some other critics, notably the medical men, are saying on the general subject of the Pharmacopoeia. I do this all the more willingly inasmuch as it appears to me there has been in certain quarters an attempt to depreciate the services of the pharmaceutical editor, and this has given no little pain to many pharmacists, more especially as it has been so utterly undeserved. I do not say it has been consciously intended by the majority of the critics, for the medical writers in question have, as a rule, adhered to their brief, but there can be little doubt that these articles, following on the discussion in the General Medical Council, give ground for the belief that a "dead set" is being made on the present system on which the Pharmacopoeia is compiled, and this is being done in a way that some of us hardly approve of. By all means let the new imperial pharmacopoeia be thoroughly modernised, introduce novelties all round if the Medical Council say it is to be done, make the Pharmacopoeia a complete text-book in pharmacy, materia medica, chemistry, therapeutics, and a prescribers' made medica all rolled into one, if they please, but, at the same time, we have a right to ask the critics to remember that the work which most of them have been engaged in denouncing did not profess to supply any single one of these demands, and for them to blame the editor, inferentially, for its supposed defects in these directions is decidedly unfair.

Within the last two months a series of articles on the Pharmacopoeia has been contributed to the British Medical Journal by a number of very eminent men. It would be difficult to find an equal number of writers whose opinions possess greater weight in their respective spheres, and therefore anything they say is entitled to the most respectful consideration. Those who have written so far include four lecturers on materia medica, viz., Professor Lecocq, Manchester; Professor Whitte, Belfast; Professor Cash, Aberdeen; and Dr. Stockman, Edinburgh; Dr. Lauder Brunton,
Professor Dunstan, and Mr. David Howard. In addition to these articles, Dr. Stockman's remarks at the last evening meeting at Edinburgh, a paper on "Nature's Polypharmacy," by Dr. Carter, Professor of Materia Medica, Liverpool, and a letter by Dr. Burney Yeo, in the British Medical Journal, all contain important expressions of opinion that cannot be ignored.

In common, no doubt, with many who heard or read these remarks, I have carefully perused what has been advanced by the various writers, and the first conclusion I come to is that the lot of an editor who has to arrange such a mass of contradictory matter is by no means one to be envied, and the post of "medical editor or editors" proposed by Dr. Whitla, or Dr. Stockman's "committee of experts," if it is ever created, will certainly be no sinecure. The second reflection is that, after all, there is something to be said for the old B.P. yet. On the whole, it has fairly well withstood the sharpshooters who for ten years have made it their target, and even this last battery of heavy artillery has not been so deadly as one might have expected considering the great array of specialists engaged in directing the onslaught, and thirdly, it occurs to me that had some of the writers wished to be scrupulously fair all round, they might not have made so many points, but on the other hand they would probably have avoided not only contradicting their medical brethren, but contradicting themselves.

It may seem a thankless task to examine these criticisms, still if we can show that the medical specialists have no very clear idea of what they want, and that they are at least far from agreement on points regarded by themselves as important, something will have been gained if only the critics will take the obvious lesson to heart.

The main attack on the galenicals of the B.P. has been led by Dr. Whitla, and he has not been sparing of his criticism. Hardly any class of preparations has been left untouched, and the most sacred among them have been made to feel the crushing weight of his iconoclastic sledge-hammer. Indeed, if Dr. Whitla had his will there would not be much of our present B.P. left, although at the same time any hope of a new pharmacopoeia would be relegated to the dim and distant future. Fortunately, the experts do not agree, and there is still some hope that amid their disagreements we pharmacists may be able to conserve a little of the Pharmacopoeia, that will be of permanent use to the empire when the current medical fads lie buried in oblivion.

Selecting some specimens without regard to alphabetical order, we find that Dr. Whitla says of the confections that they "may be regarded as belonging to a past time, and as veterans they lag superfluous on the stage." Dr. Burney Yeo on the other hand thinks that "as a means of giving bulky, insoluble drugs, or very pungent or irritating substances in a convenient and at the same time active form, confections are most useful." Of confection of senna Dr. Yeo writes: "Improve its composition by all means, but I do not believe the time has yet arrived when the modern dislike—not a little flavoured with affectation—of polypharmacy will be able to depose our old friend the lamentative electuary." With regard to infusions, Dr. Whittu thinks "the entire group should be revised, and most, if not all, omitted, from a medical point of view"; "their strength and actions vary so much that their days are already numbered." Prof. Leech thinks "they are not looked upon with favour anywhere but in this country"; and Dr. Stockman joins the crusade, his opinion being that "preparations containing a large proportion of water, such as infusions, decoctions, and liquid extracts, could be largely reduced in number. It would be quite easy to use the tincture and add water as required." This no doubt would be a convenience if we could be certain that spirit was always the best solvent, but this is a doubtful point. Dr. Carter, for example, refers to what "practical experience seems long to have settled, viz., the superiority of the infusion (of digitalis) over the tincture in the treatment of aortic regurgitation." Dr. Yeo also comes to the rescue by declaring that "infusions should not be wholly discarded, and that fresh infusions of the fresh drug often prove more active than any other preparation." These are little differences of opinion of course which the committee of experts would no doubt soon settle, but the question arises, Would the medical profession give up infusions even if the Pharmacopoeia no longer included them? Before the dicta of specialists are accepted, we must be sure that they do no violence to the opinions and practice of the average practitioner. We find for example that a large number of infusions are exceedingly popular with the profession. From Martindale's analysis of 12,000 prescriptions, we find that there are at least a dozen that are regularly prescribed, and three or four of them occupy a high position in popular favour. Dr. Whitla's reason for giving up infusions is a curious one, "their strength and action vary so much."

Does Dr. Whitla mean that he would not object to infusions if they had all the same action? If not, what does he mean? Then it is strange that he should find fault with the varied strengths, since with another class of preparations the trouble is their varied doses. In the case of infusions, uniformity of dose has been secured, and necessarily at the expense of uniformity of strength. Dr. Whitla really ought to be consistent in his criticism, for he must remember that he cannot both eat his cake and have it. In the case of the ointments also he thinks there is "lamentable want of anything approaching uniformity." Here, again, he seems to be inclined to sacrifice everything to an idea. In the U.S. Pharmacopoeia a number of the ointments are 10 per cent., but the majority are of all strengths. It would be quite impossible to fix one strength for more than a few of the ointments; otherwise prescribers would be under the perpetual necessity of diluting certain ointments and making others stronger. Dr. Whitla's opinion of the liquors, spirits, syrups, and tinctures, is that "only a very small percentage of these 162 preparations are in use among practitioners, and the reason is obvious, the strengths and doses are so various that it is found impossible to remember either." Dr. Stockman, too, would like doses of tinctures, etc., made uniform, but he uses the term "valoids" in such a way as to suggest that he is not quite
sure of his ground. Valoids have no relation whatever to dose; they are preparations—liquid extracts, in fact, in which one ounce represents an equal weight of the drug. If, therefore, this principle of valoids were adopted the dose would be still more varied. It is not clear whether Dr. Whitla would like to assimilate the strengths or the doses, but it is evident that in any case either the one or the other must always be "various," and therefore his criticism loses half its force the moment it is examined. As to the statement that "only a very small percentage" of these preparations are in use, it is a sufficient refutation to quote some figures from Martin dal’s analysis. Out of 150 preparations, viz., liquors, syrups, spirits, and tinctures, one was prescribed upwards of 1000 times; 28 were prescribed from 100 to 1000 times; 58 from 10 to 100 times; and 46 under 10 times; only 18, of which 12 were liquors, not having been prescribed at all. If this is an average set of figures, and there is no reason why it should not be, it will be seen that if we reckon on fifty million prescriptions in the course of the year, the probability is that the correct thing would be to say that "only a very small percentage" are not in use. Hardly anything is as red from Dr. Whitla’s onslaught. The wine "should probably be excluded"; decocations, plasters, and extracts contain "numerous examples of inert preparations"; vinegar "ennumbers valuable space"; the lozenges are "a very doubtful addition"; mustard paper is not a success; and the poultices are "a serious blemish." Cataplasm, coffin is a veritable silt to the critic, for no fewer than three of them make the subject of lengthened comment. Dr. Whitla thinks that the enemas "afford the best examples of official preparations framed in opposition to the recognised principles of physiology and therapeutics," but to laymen it sounds strange to hear that the recognised principles of physiology and therapeutics should have altered so much in ten years. Of course there is the alternative proposition, that Dr. Quain and his colleagues were ignorant of these principles, and so permitted a glaring error to pass, and probably this is the true explanation, as even to-day these are men who think highly of these preparations. Dr. Lander Brunton, for example, says that enema asepticida is "one of the most useful remedies in the whole Pharmacopoeia," though he would make it with the tincture, while Dr. Yeo joins issue with Dr. Whitla, and is of opinion that "the Pharmacopoeia should contain a few typical examples of this very useful mode of administering medicine," and he also proposes to add a "typical nutrient enema." It is sad to think that these eminent men are so ignorant of the "recognised principles of physiology and therapeutics," and since the leaders are so hopelessly befogged, we need not wonder at what they tell us of the ignorance of the rank and file. There is only one thing more surprising than that ignorance, and it is that these learned men should take such pains to make it known. There are medical men who write prescriptions such as this—

2 Liq. Strychnine .................................. 30
Liq. Potassa ad .................................... 3
Sig.—20 drops for a dose.

But though we all know one such among our acquaintance, we all think he is the exception. It seems not, for Dr. Lander Brunton wishes the most elementary facts in chemistry stated, and apparently would like every possible reaction indicated in every possible combination of chemicals. Not content with that, he proposes that the Medical Council should "have experiments made to settle such questions" as "whether the strychnine out of ten drops of tincture of nux vomica will be precipitated by the tannin in an ounce of infusion of gentian!" Not only does he wish a table of solubilities in cold water and in hot, but he is curious to know whether certain substances that have been dissolved by heat are entirely deposited on cooling. He wishes directions for prescribing drugs, so as not to produce a heavy precipitate, a disagreeable colour, or an abominable taste; for now that the doctor knows so little practical pharmacy he is liable to make these little blunders, and where he does not dispense his own prescriptions he has "no chance of rectifying his mistake" when the medicine is made up. Dr. Yeo is also strong on the ignorance of the young medical man in this direction who "knows so little of practical pharmacy or of the art of formulating" that the hypodermic syringe is for ever in request, "and its indiscriminate use is responsible for more serious consequences than I like to contemplate." He believes that many deaths have been caused by the incautious use of the morphine injection, which is far too strong; so strong, Dr. Whitla also thinks, as to be "positively dangerous." In this connection I may refer to Mr. Naylor’s proposal to make the potent remedies have a strength of "10 grains in 100 minima." Apart from the difficulty of making some of the solutions of this strength, I think that 10 per cent. is needlessly high; besides, for purposes of calculation, 1 per cent. is almost equally simple, and that strength has much to recommend it. What strikes me as very curious is that Mr. Naylor should propose the adoption of the metric system of weights and measures, and at the same time violate its main principle by making his liquors 1 in 9! Generally speaking, this discussion of the Pharmacopoeia has begun and ended in criticism. There have been few suggestions of any value by way of addition or improvement, but regarding those that have been made there is no more agreement than there is with reference to the criticis of I have quoted. For example, Dr. Lander Brunton wishes cacti and tabloids made official, and Dr. Whitla hints that the "recent perfection of the manufacturing of tabloids" would suggest that there be substituted for lozenges. On the other hand, Dr. Yeo speaks of the "uncertainty of the compressed tabloid, with which we are at present a little overwhelmed," and Dr. Stockman objects to its use in medicine, and he thinks introduce capsules, these late, however, being exactly what Dr. Lander Brunton wishes to introduce, as they are "useful aids in administering disagreeable medicines. Dr. Yeo’s opinion is that capsules in certain cases "cause such an amount of gastric irritation as to contra-indicate their use, but these drugs," given in the form of confection, "are admirably tolerated." The committee of experts will here have to decide.
whether capsules are to be introduced or not, and if they are, what medicines are to be administered by capsules and what by confections. It will be well to be precise on these points, as it is apparent that the degeneration of medical men in practical pharmacy will increase rather than otherwise, and if the Pharmacopoeia is to be made up of milk for these babes, certainly the information ought to be as complete as possible. Further, if all the "useful aids" for administering disagreeable medicines are to be included, it would hardly be fair not to recognise much more universal aids even than capsules, namely the raspberry jam and the red currant jelly of our tender years!

The question of therapeutics has also been raised. Apparently none of the foreign pharmacopoeias referred to by Dr. Leech take up therapeutics. But our new imperial pharmacopoeia need not be hampered by precedents. Dr. Lander Brunton thinks "some indication of the action of medicines" would be an innovation warmly welcomed. Certainly it would be an innovation, and it might be welcomed, though I do not see why it should be, since medical men are specially trained, or ought to be, in therapeutics, and have text-books dealing entirely with that branch of their profession, but I question if it would be so favourably received ten years hence. We can, if we like, stereotype the formula of a tincture, but it would be perfectly hopeless to attempt to stereotype the diseases for which that tincture will be prescribed within the next month, not to speak of ten years. Dr. Whitley is even more emphatic. "The time has now come when the work (of framing the Pharmacopoeia) must be undertaken in a totally different spirit, and the revisers must go to the root of the matter and produce a volume which will be an index of the advanced pharmacy and therapeutics of the day," and he adds, only too truly, "it will take at least a few years before this result can be accomplished."

It appears, therefore, that any hope of soon seeing an imperial pharmacopoeia must be given up if these authorities have their way.

It has been for some time considered fashionable to sneer at what is called polypharmacy, and some of the authorities are anxious that preparations of crude drugs should be displaced by solutions of their active principles. Professor Cash makes a remark which has a general application. "It is," he says, "neither conducive to the accuracy of pharmacological research nor yet of treatment, that we should work with bodies whose constitution is not understood, or which may contain principles divergent or even antagonistic in their action." Admitting this to be correct, what are we to say of digitals, which contains antagonistic active principles, and of which Dr. Stockman says, "nobody has ever worked up the subject with such exactitude that one can feel justified in departing from the use of the leaves"; of ergot, of which "our chemical knowledge is still more deficient"; of hyoscymus, of jaborandi, and numerous other drugs that might be named? Regarding some of these, Dr. Stockman thinks that the new edition will be indefinitely postponed if such points are to be worked up and determined, but, nevertheless, his committee of experts no doubt "could easily in a few meetings decide" where we are to draw the line in applying the principle of abolishing polypharmacy. There are many drugs of which we need not be in doubt, but what of those that lie on the border line? Dr. Stockman would discard tincture and extract of nux vomica for strychnine—oblivious of the fact that the tincture is prescribed in the proportion of 3 to 1 of the liquor—substitute atropine for belladonna, eserine for ephedrine, tanin acid for powdered galls, and so on. Dr. Lander Brunton is also on the same side; he thinks that the B.P. pills are too large, and that they should be replaced by granules the size of a pin's head; but even these are not perfect, as patients have been known to mistake arsenic granules for homeopathic pills, and swallow them accordingly, very much to their discomfort.

Dr. Stockman agrees that pills are too large, and would have them reduced by omitting all but the active ingredients. His committee of experts would therefore have to determine the active ingredients in rhubarb pills, colchicum pills, aloe and iron pills, and so on; retain these and leave out all that is not active. If this means that by so doing he would secure pills of the same strength, but half the size, his committee would find its work cut out for it. It is assumed in all this that the experts would agree among themselves, but are we certain that they would? Professor Carter is an expert, and what does he say?—"An increasing knowledge of the constitution of many of our old-established and best approved remedies proves that on safe ground some degree of polypharmacy is justifiable," and as illustrations of this fact he gives jaborandi, digitals, opium, and calabar bean as natural examples, and Warburg's tincture and Graves' prescription for dropey as valuable medical examples of polypharmacy. If therefore the committee of experts be a representative one the task might not be so simple as some would expect, and the chances are that the "few meetings" would be gradually drawn out to the "few years" required by Dr. Whitley for carrying out his programme.

I close this already too long paper by referring to a remark made by Dr. Stockman, who thought the pay should go to the men who did the work. Admitted—but I rather think difference would still arise as to the distribution of the pay. He would, for example, very likely think that the addendum committee should have been considered, but in that case someone else might wish to institute an inquiry in order to see how the matter would stand on the principle of "payment by results." If that were done, it would probably be found, as Dr. Stockman states, that one-third of the addendum galenicals are never prescribed and could be dropped out; that three-fourths of the remainder were "lifted" almost without a word of alteration, and certainly without a word of acknowledgment from the B.P.O. formulary and the Extra Pharmacopoeia; and finally, that the effective result of the committee's labours consists of an abortive substitute for eucynam that not one doctor or pharmacist in twenty will look at, with a couple of ointments, one of
which at least cannot be called a success. Would Dr. Stockman be satisfied with a "show," like this for his money? Seriously, I do not think it is fair to hint that the editor gets paid for other people's work. So long as Professor Attfield occupies the position of editor of the Pharmacopoeia and bears the responsibility for that important national publication, so long ought he to be paid accordingly, and no one who knows anything of his work in the past will doubt that he is the very man for the place. The work of editing a Pharmacopoeia does not consist in evolving arm-chair formulae—neither does it consist in doing porter's work in a wholesale laboratory. From the nature of the case the Pharmacopoeia in this country will always be the product of the work of many men, each working not for pay, but for love of the work, and with not even the ulterior aim of his work ever being officially recognised. No matter what committees are appointed, there will be always others outside the committees whose work has to be taken account of. It is one of the functions of the editor to separate the wheat from the chaff, and preserve what is worth preservation, whoever the worker may be; that Professor Attfield has done this part of his work with conspicuous success no one can deny.

**PHARMACOPOEIA PROCESSES.**

BY J. B. STEPHENSON.

My contribution this evening consists of a few notes which I have been led to make on some of the processes in the Pharmacopoeia, in the course of putting them in operation.

**Acids.**—I have always regarded the directions for diluting the hydrochloric, nitric, and sulphuric acids as unfortunate. We are told to dilute them with so much water, and then to add as much more water as will bring them to the desired measure at 60°. I can imagine a loyal man following this direction implicitly once, but I am sure he would note the quantity of water required to bring up the measure, and the next time he made the preparation would add it to the acid at once along with the rest, and this is what I think the compiler should have done if it was necessary that the strength of these diluted acids should be adjusted with as much accuracy as if they were volumetric solutions, but is this really necessary? They are used, I suppose, exclusively for medicinal use, and I should imagine a slight variation in strength quite immaterial.

As the formulae stand they are very apt to lead to confusion and mistakes in calculating different quantities than those ordered. These quantities also differ strangely among themselves. In the case of hydrochloric acid it is 264 fl. oz.; nitric, 51 fl. oz.; and sulphuric, 83½ fl. oz. After what I have said I need not add that I think the alternative process of making these preparations by weighing the acids and diluting to the required measure quite unnecessary.

**Acid Nitro-Hydrochlorur. Dil.**—In the 1867 Pharmacopoeia this was made by mixing the strong acids, setting stand for twenty-four hours, and then diluting with the water. There had been a complaint that some of the chlorine was lost in following this process, and the present plan was adopted in the 1885 edition of diluting the acids at once and keeping for fourteen days before use. There is certainly no loss of chlorine here, and for the best of all reasons, that there is none to lose, for it is not formed—at least, in any appreciable quantity.

**Bmp. Belladonnae** is, I think, too strong—1 to 4—and it is too soft for a plaster. Made of the strength of 1 to 7—surely strong enough—and with plain resin plaster, it is a perfect plaster.

**Ex. Cascara Sag.**—The bruised bark is exhausted readily and completely by percolation with cold water, allowing it to stand well moistened with a sufficiency of the water for twenty-four hours previously.

**Glycerinum Acid. Tanac.** is quite readily prepared in the cold. When heat is applied it is apt to become discoloured by keeping. There is an old suggestion, and I think it worthy of adoption, to dilute the glycerin with water. From an eighth to a twelfth of the latter added to it makes the preparation more convenient to use, especially in cold weather. I have heard the objection stated to this that it is desirable to have a very thick application so as to adhere to the part better. I can only say that I have not heard of this objection being valid in practice.

**Glycerinum Boracis.**—The addition of water is ordered, but there is too much—1 part to 2 of glycerin makes it unnecessarily thin. I would suggest that the addition of water, say one-tenth or one-twelfth, should be ordered in all the glycerinas, which are thick viscous solutions.

**Glycerinum Tragacanthae** is too stiff. One-half or two-thirds of the quantity of tragacanth makes a much more suitable pill excipient.

**Linimentum Terebinthine.**—The difficulty with this preparation is simply a question of the quantity of water. The soap, of necessity, varies in the amount of water it contains, and the water used should vary accordingly. The formula should order as much water as will form a thick cream with the soap.

**Liq. Caleis Sacch.**—It would be an improvement to order the sugar to be dissolved in the water and then the lime to be added.

**Suppositories.**—In such as tanin, iodoform, and morphine, the quantity of the medicinal ingredient is deducted from the sl. theobrom. ordered. This is misleading, because the mass so made will not yield twelve 16 gr. suppositories. Of course they will weigh 15 grs., but they will not fill a 16-gr. mould.

**Syrups.**—The strength is adjusted so as to give a saturated solution of sugar, but under the ordinary conditions of the shop they all crystallise. One-twentieth more of water would obviate this.

**Tinctures.**—The process by which most of these are to be prepared has been much criticised and condemned. The ingredients are to be macerated for forty-eight hours in three-fourths of the spirit, then percolated, and the remaining fourth to be passed through the marc. In many cases—perhaps in all—the forty-eight hours might be changed to twenty-four, and a somewhat larger proportion of the spirit
might be reserved for washing the marc, but I think that on the whole, and as a general process, it will be found to yield a more uniform and satisfactory result than any other. It is quite applicable to tint. auranti, which is ordered to be made by maceration only. The maceration in tr. myrrhe is quite unnecessary. The myrrh should be placed loosely in the percolator and the spirit poured on it at once. It passes through readily and exhausts it perfectly. The general process should not be ordered where there is a very small quantity of material to be operated on, as in the case of tr. capsici, nor is it suitable, nor indeed possible, where the quantity is large or bulky as in tr. lapuli. Nor do I think it is suitable for tr. cellas or tr. calumba, which should be made by maceration. The tr. iodii will surely be increased in strength to that of the old Edin. tincture (3o. to 3o.), after all that has been said about it, and the application of heat will also be omitted in tr. quin. and tr. quin. am. It is quite a blot to have it mentioned. I would be very chary in adopting any spirit weaker than proof for tinctures. Before doing so, I think it would have to be proved conclusively not only that the tincture so prepared is stronger and better, but also that it is equal in keeping properties to that made from proof. The value of a tincture as a pharmaceutical preparation consists greatly I think in this latter.

Unq. Acid. Boric. may be made more readily than by sifting the boric acid into the melted paraffin, by rubbing the solid in a warm mortar, adding the melted paraffin, and stirring diligently till cold.

**GENERAL NOTES.**

**BY GEORGE COULL, B.SC.**

It may or may not be matter for congratulation during the present "spate" of addresses, lectures, and letters on the new edition of the Pharmacopoeia that the discussion of the subject was initiated in Scotland. What struck one most forcibly who listened to the discussion following Professor Charteris' lecture was the clear and sharp division of opinion on the question of expunging many articles from the Pharmacopoeia. The one portion of the camp was composed of the medical contingent and our younger brethren, and the other consisted of the fathers of the craft. The former agree with the professor in his policy of deletion and the latter say—abolish not the landmarks.

Now all this discussion may be not without its due value, but there is one thing that we as pharmacists ought not to lose sight of, and that is, that it is really not our province to say what is and what is not to be included in the Pharmacopoeia. It is the prerogative of the medical profession to do this thing through its representatives—the General Medical Council. After they have stated what drugs and likely preparations of these drugs are to be made official, our part is then to step in and aid them in their helplessness by showing how these drugs may be best exhibited, and fixing standards and tests for those whose purity can be determined by chemical examination.

If we are asked about the relative frequency with which certain drugs and preparations are sold, let us give all the information we can, but let us not insist, bon gré, mal gré, on the insertion or deletion of particular articles. These are matters of opinion, and where our opinion conflicts with that of the medical profession the chances are that ours will be ignored. On the other hand, improvements in processes and tests that are the result of direct experiment are always of value.

It is satisfactory to note that the General Medical Council has requested the co-operation of pharmacists in the revision of the Pharmacopoeia, but this is ex gratia; my opinion is that we should consider it as our right to have a hand in helping to frame the national Pharmacopoeia, and not look upon it as an honour for which we ought to feel devoutly thankful.

Dr. Lauver Brunton, in his now historic article in the British Medical Journal, says the Pharmacopoeia is primarily intended for the medical man. As I read the preface to the B.P., 1867, I see nothing to that effect. "It is intended to afford to the members of the Medical Profession and those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide. . . . . . . . . . . . . . . . . . . . " A careful reader will observe that the punctuation here is slightly different from Dr. Brunton's; he introduces commas after "Profession" and "Empire," as if the words between the commas were parenthetical or of secondary importance. In the original there are none, and the medical profession and pharmacists are to be taken as equally concerned with the said standard and guide. The reason the medical profession is placed first is, of course, simply a question of precedence.

The one thing in Dr. Brunton's paper about which I think we are all agreed is the desirability of a table of solubilities, or at any rate a thorough revision of the solubilities already given. If by any mischance this new imperial pharmacopoeia is converted into a prescriber's and dispenser's pocket companion, giving notes on incompatibles, therapeutics, and how to make presentable ophthalmic emulsions, it will be subject for mirth among the civilised nations of the earth. While on the subject of Dr. Brunton's paper I may be allowed to point out a bad slip he made in referring to tincture of chloroform and morphine as compound tincture of chloroform. The entire article may be alliteratively summed up in two words—distinctly disappointing.

A few of the following remarks I have made on previous occasions (sometimes repetition is necessary before a statement is accepted as fact), and some may be unnecessary, owing to the deletion of the article from the Pharmacopoeia.

What is specially wanted in the Pharmacopoeia from the pharmacist's point of view is much more explicitness in the application of tests and in the preparation of galenicals. Several examples will be given below, and there are, I have no doubt, many more. The name of the body which the application of a test is supposed to indicate ought to be inserted. Why this should be surely needs no argument.

Does ought still to be included after being revised,
as a guide to the pharmacist. If he has to get his doses from a book on therapeutics, he will naturally acquire some theoretical knowledge of the actions of drugs, and, being only human, the temptation to sometimes prescribe will not be resisted.

Chemical formulae should be given more in accordance with modern chemistry, as showing the constitution of the substance. This principle has been partially adopted in the additions, 1890, and rather unequally. Acetanilide and sulphonamide are given correctly, guaiacum should be—

\[ \text{C}_6\text{H}_4\left(\text{CO}\right)\text{SO}_3\text{NH} \]

Benzoic sulphimide or o-sulpho-benzoic-imide, and it might with advantage be added that it is the inner anhydride of o-sulphamino benzoic acid. It is not attempted to give a constitutional formula for phenacetin, \( \text{C}_6\text{H}_4(\text{OCH}_3) \) (NH.C_6H_2.O) acet-o-phenetidin, and sodium benzoate is stated to be Na.C_6H_4.OH, which is quite correct, but it would be better to give \( \text{C}_6\text{H}_4\text{OONa} \) as the formula. Acetic, benzoic, and carboxylic acids, acetic ether, butyl chlorhydrate, chlorhydrate, and indeed all organic compounds whose constitution is known, should have their constitutional formula appended.

**Acids (Dilute).—** If these were all made by weight, much time would be saved in waiting till the diluted acid attained the temperature of 50° F. (15° C.) before being made up to the volume ordered. The test for sulphuric acid in several acids by means of the reducing action of hydrogen—with formation of sulphuretted hydrogen, and subsequent blackening of lead acetate paper held in the mouth of the flask—could be much simplified by ordering that solution of iodine should not be decolourised by the acid, with the addition of starch if further refinement is desired.

**Acidum Carbolicum.—** I observe Mr. Lunan has been advocating the introduction of the bromine assay process. The only use for this is to approximately determine the amount of carboxylic acid present in a mixture of carboxylic acid and water. The substance most likely to be present in carboxylic acid is cresylic acid in one or more of its modifications, and it, in common with all phenols, forms substitution products with bromine in a quite analogous manner. It might be of some little use if introduced under the name of liquesficientum, but I do not think it can be of much value under acidum carbolicum. If the melting point and boiling point are altered in accordance with my suggestion, we shall have a very good article. Bromine water is said to give a white precipitate with a cold saturated aqueous solution; as a matter of fact, even very dilute solutions give a precipitate.

**Acidum Hydrobromicum Dilutum.—** A test for sulphurous acid ought to be given, sulphurous acid or a sulphite being sometimes added to decolourise the acid when it has turned brown. I find that a very pure acid is the result of the action of bromine on phosphorus. This is probably one of those articles which is about to be omitted in the new pharmacopoeia. There appears already a sufficiently unanimous consensus of opinion both on the medical and pharmaceutical sides regarding the desirability of this. The specific gravity of a 10 per cent. acid is stated to be 1-077. Squibb casts a doubt on this, and I found when preparing some in the manner indicated above that the specific gravity 1-0715 corresponds to about 10-4 per cent., and 1-0749 to about 10-36 per cent. of real acid. This will require to be corrected.

**Acidum Hydrocyanicum Dilutum.**—The B.P. method of determining prussic acid is decidedly troublesome, and the U.S.P. process is a distinct improvement. It consists in adding the acid to an excess of magnesia in water and titrating with silver nitrate, using potassium chromate as indicator. Squire says manufacturers purposely add a trace of hydrochloric acid to prussic acid to retard decomposition, and that the U.S.P. process reckons as cyanide any chlorides that may be present. This is very true, but the B.P. gives a test for hydrochloric acid, the U.S.P. does not; it intends the process to be used to standardise the recently prepared acid, in which there ought to be no hydrochloric acid present. If an acid is necessary, or desirable for preservation, might I suggest the employment of sulphuric acid and the inclusion of a standard?

**Acidum Meconicum.**—The formula should be stated as to show the basicity of the acid.

**Acidum Oleicum.**—Mr. Dott objects to the term "fatty acid" being applied to this acid, and I agree with him. Perhaps the term "unsaturated fatty acid" would be sufficiently accurate.

**Acidum Phosphoricum.**—A much simpler and more easily performed determination of this acid would be by means of caustic soda and phenol-phthalein, remembering that the change of colour occurs when two-thirds of the acid is neutralised. This, I submit, is even better than the uranium process suggested by Mr. Lyom.

**Acidum Tartaricum.**—This is a case where we ought to have more definite tests. An aqueous solution of the acid is not affected by sulphuretted hydrogen. This, apparently, excludes all soluble salts of lead, but does not exclude metallic lead. There ought to be a standard laid down and a certain way of performing the test, in order to obviate all ambiguity and save us from the "beaum" of the omnipotent public analyst.

**Aqua.**—The instructions for preparing most of these are to take a certain quantity of the bruised drug and two galls of water, and distil one gallon. If one simply followed these directions, and sent out the water as it came over, he would soon hear of it. Customers simply will not have waters that are not perfectly bright. An excess of oil comes over and floats on the top of the water, which has quite a milky appearance. The water has to be separated from the oil and filtered at as low a temperature as possible, in order that it may not again become milky when the temperature falls. I am not sure but that the suggestion which has been already made to follow on the line of the U.S.P. would be a vast improvement on our method.
Ginchna.—In the assay of this drug the temperature at which the quinine is to be dried should be stated, and its composition indicated—anhydrous, monohydrate, or trihydrate.

Choral Hydras.—Formula should be given as CCl₄·CH(OH)₃, showing that the water is chemically combined and not merely water of crystallisation.

Decoctum Pareirea.—In the preparation of this galenical pareira root is ordered, and in the case of the liquid extract the solid extract is used, the idea being that you get a more uniform liquid extract owing to the variation in the quality of the root. I think it is rather inconsistent to use the root in the one case and the solid extract in the other. In fact, it may be said without trenching on the medical man's ground that this is one of the redundant preparations of the Pharmacopoeia.

Ergotinum.—The instructions here involve a foolish waste of valuable material. I wonder how many makers adopt this process.

Extractum Cimicifugae Liquidum.—Why is rectified spirit ordered here, and proof spirit in making the tincture?

Extracta Liquida.—I am strongly in favour of re-percolation being employed in the preparation of liquid extracts, and I would further make them all one in two. There would then be no necessity for evaporating the last portion of the percolate as in the case of coca, which might as well be omitted for all the cocaine you get to survive this treatment. I do not think there are many, if any, drugs whose soluble matters are not entirely extracted by being treated by re-percolation to make a one in two preparation. Another advantage would be that some tinctures might be expunged as redundant.

Ferris Carbonas Saccharata.—Dr. Whitta in his recent article says commercial specimens prepared by the official process generally yield about 20 per cent. of real ferrous carbonate. I have previously pointed out that it is quite easy to prepare this by the B.P. process to contain the proper proportion of ferrous carbonate. It may be further added that if kept dry there is no danger of oxidation; it is not so much the exposure to air as the presence of moisture that does the mischief.

Ferris Phosphas.—The standard for this is none too high; in fact, it could easily be raised, but the directions for making would require to be amended. The present process does not give such a high percentage of ferrous phosphate as may be got from the same quantities differently manipulated. Recent batches have given me 67·3, 70, 56·3, 51·2, and 69·3 per cent. The amount of oxidation depends on the manner of mixing the solutions, the temperature of the solutions, the manner of washing the precipitate, and the temperature at which it is dried. There is no more certain way to oxidise a ferrous precipitate than by washing it on a calico filter, a fresh portion of the precipitate being exposed to the air after each addition of water. I intend to examine the different methods of making ferri phosphas and report.

Olycerynum.—A test for arsenic should be inserted, leitmann's or Gutzeit' s.

Infectio Apomorphina Hydrochlorata.—It is impossible to get all the apomorphine hydrochloride into solution.

Linimentum Saponis.—Soft soap makes a perfect solution very quickly.

Linimentum Terebinthina.—Doubling the water, as several have recommended, works well with some samples of soap, but with others it is of no avail.

Liquor Ferri Dialysatus.—This, literally translated, is dialysed solution of iron, but the Pharmacopoeia freely renders it solution of dialysed iron. Some objection is apparently taken to the term dialysed iron. Considering that the dialysate is what is wanted and not the diffusate, I do not know of any more appropriate name to call it, only I would make the English and Latin names correspond. Potassium ferrocyanide is said not to cause any precipitate, but it has done so in every batch of dialysed iron I have made.

Liquor Magnesii Carbonatis.—I once suggested the use of sulphuric acid and methyl-orange as the most satisfactory method of determination. Since then I have used cochineal as indicator, and find it gives a much sharper and reaction than methyl-orange. I therefore suggest that this method be adopted.

Liquor Plumbi Subacetatis.—A useful addition to the instructions here would be to order distilled water recently boiled and cooled to be used in diluting to the proper strength. Before it occurred to me to boil the water I used to be greatly annoyed by the cloudiness which often appeared on dilution, through the absorption of carbonic acid by the distilled water.

Liquor Potassae.—Under this solution as well as some others a definite specific gravity and a definite percentage strength are given. It is only when dealing with chemically pure materials that we can get a definite specific gravity to correspond to a definite percentage strength. I am of opinion that this is a suitable place for the insertion of that much maligned little word "about." Either make the specific gravity or the percentage the fixed quantity and the other the variable, or insert "about" before both of them.

Liquor Zinci Chloridis.—When evaporated to the required bulk and cooled, this solution becomes opalescent and gradually deposits what is probably zinc oxychloride. It requires the addition of hydrochloric acid to keep it clear. I have found the specific gravity to be 1·569 and 1·583; the B.P. gives 1·460.

Mistura Ferri Aromaticata.—Some say that this should be filtered after the addition of the tinctures. I do not think it should, but it might be mentioned whether it ought to be or not.

Olea.—The great advance of late in the chemistry of essential oils necessitates the inclusion of chemical tests and physical constants brought up to date.

Opium.—The next pharmacopoeia must state whether the strength of preparations of morphine is to be calculated on morphine hydrate or on anhydrous morphine. At our last evening meeting Mr. Dott said that tincture of opium should be standardised to contain 0·75 grammae morphine hydrate in 100 C.c. The strength of the tincture at present is calculated
on morphine dried at 90°, 100° C. In the case of a substance like morphine there should be no ambiguity.

Potassii Tartratis Acida.—There is now no difficulty in obtaining this to contain 99 per cent. acid tartrate. The volumetric determination with caustic soda and phenol-phthalein ought to be introduced in place of the cumbersome method of ignition, and a test given for sulphates, potassium bisulphate being a possible adulterant which would use up more soda weight for weight than the acid tartrate would.

Spiritus Ammonis Aromaticus.—After adding the quantity of barium chloride ordered in the test for carbonate and filtering, the addition of more barium chloride sometimes does not give a further precipitate, but on heating the precipitate is at once formed. Here again there should be more exact definition. I have never seen the text-book fact taken into consideration that precipitates of barium carbonate are slightly soluble in ammonium chloride. I have used for some time ochinmeal as an indicator in the titration for total alkalinity, and find it all that could be wished.

Spiritus Armoraciae Compositus.—As in the case of the waters the oil comes over and floats on the distillate. We are not told to separate it and filter.

Volumetric Analysis.—There can be no doubt in the mind of most people that full advantage is not taken in the Pharmacopoeia of the, generally speaking, beautiful simplicity, mathematical exactitude, and fin de siècle expedition of the methods of volumetric analysis. A detailed statement of what is absolutely necessary would take too long to enter fully into now, suffice it to say that the principles of this branch of analysis could be enormously extended in the Pharmacopoeia.

(to be continued.)

Proceedings of Societies in London.

CHEMICAL SOCIETY.

At a meeting held on Thursday, March 21, a series of communications from the University of Prague, Bohemia, by Professor Brauner and his pupils, were read by Professor Brauner:—

DETERMINATION OF SUGARS.

The determination of sugars by Pavy's method is attended with no considerable difficulty, and it has been shown that only under certain conditions can concordant results be obtained. These difficulties are due to oxidation by the air, and the usual method of overcoming this difficulty, by working in a current of inert gas, as nitrogen or hydrogen, is not available, since ammonia is carried away by the current of gas. The authors recommend the titration to be performed in a beaker containing the Pavy-Fehling solution (Fehling's solution and ammonium), which is covered with a layer of heavy paraffin oil. The orifice of the burette dips under the oil, the sugar solution is added, and the titration conducted in the usual manner.

Working in this way, concordant results were obtained.

ACTION OF HYDROGEN SULPHIDE ON ANTIMOMIC, ARSENIC, AND TELLURIC ACIDS.

These investigations were undertaken to find out what products were formed during the above interactions, and if any evidence of the existence of a tetrathysulphide of antimony, Sb₂S₄, could be obtained.

The authors were not able to adduce final evidence of the existence of this compound, but show that there is a probability of its existence from analogy with the double salt 3KCl₂SbCl₄, which is a stable and definite salt.

When excess of hydrogen sulphide is passed through the solution of antimony acid, it is possible, by having a quick current and working at a low temperature, to obtain an immediate precipitate which consists of antimony pentasulphide, Sb₅S₉.

If, however, the current is slow and the temperature raised, a precipitate slowly forms which consists of sulphur and antimony trisulphide Sb₂S₃.

By working under certain conditions, the authors have been able to obtain evidence of the existence of an antimony sulphoxy-acid. When hydrogen sulphide is passed through antimonial chloride a precipitate is obtained, under certain conditions, of sulphur and antimony trioxide. In addition to the acids known as sulphantimonic acid, H₂Sb₂O₆ and antimonial acid, H₂Sb₃O₆, there probably exists an intermediate compound of the formula H₂Sb₂O₅, which, however, is an unstable acid, the salts of which cannot be prepared, and on evaporation to dryness yields antimony trioxide and sulphur—

$$2H₂Sb₂O₅ = Sb₂O₃ + 3H₂O + S$$

The corresponding salts of the sulpharsenic acid are, however, known.

THE ATOMIC WEIGHT OF TELLURIUM.

Very careful re-determinations of the atomic weight of this element by means of analyses of the tetrabromide and telluric acid lead to the value as 127-71. This atomic weight, however, does not at all agree with the position of the element as shown in a portion of Mendeleef's table below.

<table>
<thead>
<tr>
<th>N(14)</th>
<th>O(16)</th>
<th>F(19)</th>
<th>A(80)</th>
</tr>
</thead>
<tbody>
<tr>
<td>P(31)</td>
<td>S(32)</td>
<td>Cl(35.5)</td>
<td>?</td>
</tr>
<tr>
<td>As(75)</td>
<td>Se(79)</td>
<td>Br(80)</td>
<td>?</td>
</tr>
<tr>
<td>Sb(120)</td>
<td>Te(125)</td>
<td>I(127)</td>
<td>Te(130)</td>
</tr>
</tbody>
</table>

It will be seen on reference to this table that if tellurium has the atomic weight 127-71, it must fall on the other side of the halogen to that occupied by sulphur and selenium.

Since tellurium has undoubted analogies with these latter elements, the author is of the opinion that the tellurium examined by him is a mixture of elements—perhaps two, with atomic weights 125 and 130.

The telluric acid used was very carefully purified from sodium tellurate, which was fractionally precipitated in a similar method to that used in the separation of the rare earths.

Each fraction, however, gave the same results on analysis, and the only evidence that it was not an element was the fact that tellurium dried in an inert gas gave different results to those when sublimed in a current of hydrogen.
If, then, there are two elements, the true tellurium would have an atomic weight of about 125 and fall in the sulphur group, and the other element would be one of atomic weight 130, and would fall in the eighth column or argon group.

The following papers were also read.

**NOTES ON THE HYDROLYSIS OF MALTOSE BY YEAST.**

**BY DR. MORRIS.**

Fischer (Ber. xxvii., 2985), has recently shown that yeast extract (made by digesting 1 part of air-dried beer-yeast (Frohberg type) with 15 parts of water for 15 hours at 30°-35°) readily and completely effects the conversion of maltose into glucose. This re-action being remarkable, since ordinary yeast has not been known to produce glucose during fermentation, the author repeated and extended the experiments. With ordinary yeast and pure culture of Frohberg yeast, no glucose could be detected during or after fermentation, but when the air-dried yeast was used, glucose was readily formed and identified. This might be due to either the presence of micro-organisms taken from the air during the drying of the yeast, or to the feeding of the yeast cells on each other when dried. Experiments, however, showed that to neither of these causes could the difference in the action of yeast and air-dried yeast be ascribed.

The author is engaged in investigating the cause of this remarkable difference.

**STUDIES IN ISOMERIC CHANGE. PART III. THE ETHYL-BENZENE-SULPHONIC ACIDS.**

**BY DR. G. T. MOODY.**

The author has previously shown that toluene yields on sulphonation a mixture of ortho-, para-, and meta-sulphonic acids, but that other benzene hydrocarbons, xylene, etc., yield only the para acid on sulphonation. The experiments were now extended to the sulphonation of ethylbenzene, C₈H₈C₂H₅; which was found to yield only the para-sulphonic acid, 1,4-C₈H₈(C₂H₅)SO₃H. This is contrary to most of the statements previously made, but these results were probably due to the use of impure ethyl-benzene. The material used in these experiments was very carefully prepared, and great pains were taken to ensure the purity of the hydro-carbon before sulphonation. The author prepared the ortho-sulphonic acid from para-brom-benzene, and found it to be a most unstable acid, yielding the para-ethyl-benzene-sulphonic acid on the slightest elevation of temperature, evaporation on a water bath being sufficient to bring about this change. No trace of ortho-acid could be found in the sulphonation of ethylbenzene even if conducted at low temperatures, the sole product being para-ethyl-benzene sulphonic acid, 1,4-C₈H₈C₂H₅SO₃H.

**SULPHONATION OF ETHOXY-NAPHTHALENE.**

**BY MR. LAPWORTH.**

Experiments were conducted in order to see if the presence of the ethoxy group in place of hydroxyl or hydrogen in naphthalene made any difference in the position taken up by the sulphonic radical during sulphonation.

It was found that on sulphonation of β-ethoxy-naphthalene the sulphonic radicals took up exactly the same position as in the sulphonation of naphthalene or β-naphthol, yielding a mixture of 1' or 3' acids.

\[
\text{SO}_2\text{H} \quad \text{OH} \quad \text{OE}^+ \quad \text{SO}_2\text{H} \quad \text{OH} \quad \text{OE}^+ \\
\]

By modifying the process, however, and using ethyl-sulphochloride to produce sulphonation, an intermediate product was obtained, which was 1-2 ethoxy-naphthalene sulphonic acid. This acid, however, was unstable, and easily decomposed at the ordinary temperature to a mixture of the acids 1' or 3' given above.

The replacing of a hydrogen by either the hydroxyl or ethoxy radical makes no difference in the position taken by the sulphonie radicals on sulphonation, in all cases a mixture of 1' and 3' acids being obtained.

**Sheffield Pharmaceutical and Chemical Society.**

A general meeting of the above Society was held on Wednesday evening last, at the Rooms, New Surrey Street. Mr. George Ellinor (in the unavoidable absence of Mr. Kardley, the President, occupied the chair). There was a very fair attendance, and the following paper was read:

**RECENT RESEARCHES IN THE MICRO-STRUCTURE OF STEEL.**

**BY PROFESSOR ARNOLD.**

The author said that Dr. Sorby had founded this research some thirty-five years ago, and did an enormous amount of valuable work in connection with it at that time, but since then, unfortunately, there had been no one to take up this important research, and consequently it had lain fallow. About seven years ago Dr. Sorby handed over to Professor Arnold the whole of his work, consisting of micro-slides and drawings, at the same time earnestly requesting Professor Arnold to follow up this important investigation. This he had done, and was still doing with many marvellous results, which from time to time he had placed before the public. Ordinary steel, he said, was not as commonly thought an homogeneous mass of metal. Far from this, it presented a structure very similar in appearance to that of limestone rock, showing well-defined crystals of pure iron, with some graphite and carbide of iron. To obtain a perfectly mathematical surface for microscopic investigation much care was necessary in the processes of grinding and polishing, passing as it must do through different stages from coarse emery to the finest precipitated rouge on picked wash-leather.

The stoking process was done by macerating the section in very dilute nitric acid (1 C.C. of 12 acid
to 199 C.C. water), taking care not to over or under etch. This process separated the pure carbon from the carbon compound imbedded between the iron crystals, leaving a blackened structure, and thus differentiated the section so that the various constituent crystals and carbon compound areas might be readily distinguished. The crystallising point of steel he had determined to be at a temperature of 740° C.

Professor Arnold then showed drawings from sections of normal, annealed, and hardened steels, which illustrated the structures obtained by varying the proportions of carbon put into them. A section containing 08 per cent. carbon showed only a small proportion of the compound areas, whilst 38 per cent. C. had a carbon compound area about equal to that of the pure iron crystals, the section somewhat resembling a mosaico pavement. When 98 per cent. C. was reached, the whole of the iron was converted into carbon compound, and he would call this the “saturating point of steel.”

This was a fact which had never before been actually demonstrated. The foregoing applied to the normal steels. Annealed steels were next shown with similar percentages of carbon. The “pearly compound” of Sorby here proved to consist of the aforesaid carbon compound areas, from which carbide of iron, Fe₃C, had separated out in plate-like layers. Other technical points followed.

A discussion took place at the close of the lecture, in which Messrs. Illinor, Newsholme, Ibbit, and Marshall took part, and a hearty vote of thanks was accorded Professor Arnold for his very valuable lecture.

Scottish Transactions.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

At the meeting held on Thursday, March 21, Mr. W. L. Currie presiding, the following communication was read:—

LABORATORY NOTES.
BY R. BRODIE.

I find, on referring to an old minute book belonging to the Association, that it was in the year 1863 I wrote a paper on “The Preparation of Tinctures by Percollation.”

The process was not much in vogue at that date, and the paper was very severely criticised by those who thought that the process of maceration was the best because it was the simplest and entailed the least amount of trouble. Although it was mentioned in the Ed. Ph. as an alternative process in the preparation of some tinctures, there was no attempt at explaining the modus operandi, or describing the apparatus required, hence, perhaps, the reason why the process was not more generally adopted.

Standing up for the superiority of the process in 1863, after a very few years’ experience, I can, with an extended experience of fully thirty years, confidently affirm that it is not only the most efficient, but that it is the most economical method.

My information as to the nature of the apparatus required, and as to the mode of procedure after having obtained it, was derived from Mohr and Redwood’s ‘Practical Pharmacy.’

My first percolator was a Crossie and Blackwell’s ketchup bottle, the bottom of which I cut off with a file. I followed faithfully the directions as to putting coarsely powdered glass at the bottom of the percolator (in this case it was the neck of the bottle), then a layer of clean sand, next the species to be operated upon, last the spirit. After the spirit had all passed through I poured water on the surface for the purpose of displacing the spirit or tincture remaining in the marc, but I never found this part of the process successful, and at one of the meetings at which the discussion on the paper took place, I mentioned this as a drawback, when Dr. A. M. Robertson, who was then President of the Association, pertinently asked, Why not use the tincture press? Acting on the suggestion, I used the press, and found it much more effectual than the attempt at displacement by means of water, and, of course, I have continued to use it ever since.

The displacement of the tincture remaining in the marc by means of water is still followed and advocated by some, but my experience bears out the truth of the remarks on the subject in Mohr and Redwood’s ‘Practical Pharmacy.’

I soon discarded the coarsely-pounded glass and the sand at the bottom of the percolator, using only a disc of cork resting on the ledge at the bottom as a foundation for packing the ingredients upon.

The process is now officially recognised and adopted in a somewhat modified form by the compilers of the B.P., but I stick to the old method.

Mr. Dunlop, in the paper which he read before the Association a few weeks ago, I think recommended the advisability of all following the directions given in the Pharmacopoeia for galenical preparations, in order that these might possess the same physical characteristics and strength from whomsoever obtained, but while this might be very desirable, and would, perhaps, tend to do away with the remark occasionally made by customers that this is not like what was got elsewhere, yet I do not think such a result, however desirable, could be obtained, unless these directions were more full or explicit.

The directions for preparing most of the tinctures might have been stereotyped, although applied to different quantities and to different qualities. For instance, one ounce sol. bellad. In No. 20 powder is directed to be macerated in fifteen ounces of spirit for forty-eight hours, then transferred to a percolator, and when the fluid ceases to pass the percolation is to be continued by adding an additional five ounces of spirit. Afterwards the contents of the percolator are subject to pressure, and, after mixing the liquids, the product is made up to one pint of spirit.

In the case of tinct. ergot, the quantity of ergot is five ounces, which is directed to be finely comminuted,
and it is to be treated in the same manner as the ounce of fol. belladonna.

Now after percolation is finished, and the marc pressed, which of them will require the most spirit to make up the quantity to one pint? Will it not assuredly be the tinct. argot? And the quantity to be added will depend upon how much has been obtained out of the marc by pressure, which is bound to vary according to the amount of pressure brought to bear upon it.

Now while five ounces of spirit may be able to displace the tincture retained in the case of belladonna, no one will assert that the five ounces of spirit is capable of displacing the tincture retained in the case of argot, so that the strength of the finished product will depend upon the strength of the tincture press to some extent, so I fear that there is not much chance of obtaining the result desired by Mr. Dunlop (see Redwood).

Again, in the case of tinctures made by percolation in wholesale quantities, say, twenty gallons at a time, it would be unreasonable to insist upon the same methods being followed as in the case, say, where a gallon or half a gallon is prepared.

So that while an operator on the small scale might be disposed to follow the directions laid down, the wholesale operator must be allowed to be the best judge of what method is most and best adapted for preparing galenicals in his own laboratory and with his own apparatus.

And now I would like to say something in regard to concentrated infusions. The objections to the use of these most convenient preparations are founded either upon sentiment or upon an erroneous idea as to their manufacture or upon the presence of spirit. With the hyper-conscientious individual, who takes up on principle the position that because they are not official therefore he cannot use them, there is no use arguing; but with the individual who has somehow got into his head that in their preparation they are subjected to so much long and continuous application of heat, that not only is their aroma destroyed, but their medicinal virtues either destroyed or very much impaired, and therefore he does not use them, a little verbal explanation ought to be sufficient for removing his objections; and the individual who objects to their use because they contain a proportion of spirit necessary for their preservation, which does not require to exceed 15 per cent., is scarcely worth arguing with.

Mr. Dunlop in his paper falls foul of these preparations, and uses language which seems much more forcible when read in print than it seemed to be as he read it before the Association.

With regard to the time of insuffizing being reduced so as to foster the dispensing of freshly-made preparations, I do not know whether that is so, but of course this shortening of the time must have been of material benefit to those who continue to use the freshly-made infusions, and in West End or other aristocratic localities where servants abound, and where it is not much trouble to send for medicine, it is quite easy telling them to call again in an hour or two, and it is quite easy for them to call, but in East End or working-class localities servants do not abound, and very often it is an obliging neighbour who goes for the medicine, and who, having her own house duties to attend to, cannot conveniently call back; it is in such cases that the advantage of the concentrated preparations is appreciated.

I do not intend entering into an explanation of the methods followed in making concentrated infusions. Most of those present are aware that they are made by exhausting the drug with cold water, and if any evaporation is necessary, it is only of the last and weakest portion of the percolate, which is not likely to possess any aroma and very little of the active ingredient.

But objecting to countenance concentrated infusions, even if heat were employed in their preparation would be something like straining at a gnat and swallowing a two-humped camel, as I will endeavour to show. If the long and continuous application of heat is officially recommended in the manufacture of these preparations, it is surely out of all reason to object to concentrated infusions on the ground of heat being employed in their manufacture.

But with regard to the time required being now shortened or whether the shorter time gives a more satisfactory preparation, I do not intend saying anything, only this, that the shortened time possesses little advantage when the prescription is presented just when the shop is about to be closed.

I would like to mention the little inconveniences the official formula for inf. gentian is likely to produce if a freshly prepared infusion is ordered. Should I keep a supply of lemons so that the fresh lemon peel may be at hand when a prescription, say, for two or four ounces is handed in, or purchase a lemon in the morning, and throw it away at night if it has not been required—as is done, I believe, in certain establishments with infusions, where they are made fresh every morning and if not used thrown out at night—or should I wait till a prescription does come in and then send to the nearest greengrocer, who may be half a mile away, for one? And then look how lemons vary, at one time large and juicy and at another small and shrivelled, and sometimes not obtainable at all, being out of season, and yet we are expected to make our infusion at all times.

There was a formula for mist. gent. in the Pharmacopoeia, 1867, which was deleted in the 1885 edition, and in an article by Charles Umney, on the British Pharmacopoeia, 1885, published in the Pharmaceutical Journal, he refers to this preparation as one of the discarded, and says it was in little demand and there would be no regret at its omission; it was originally transferred to a former British Pharmacopoeia from the Edinburgh Pharmacopoeia. But it did not exist in that pharmacopoeia as mist. gent., but as Inf. gentian, the name being changed because the London formula was also retained and there could not well be two preparations having the same name; but by changing the name the identity was lost, and it could not be expected that medical men who had written inf. gent. for many years could at once drop
the habit and write of mist, gent.—hence the falling out of use of the latter. But let us compare the formulæ of the two preparations:

Gentian root 60 grs. Gentian root ½ oz.
Bitter orange peel 60 " Bitter orange peel 30 grs.
Fresh lemon peel 2 oz. Coriander fruit 30 "
Distilled water to 10 2 fl. oz.

Which of them would be most serviceable as a tonic? Except as a flattering agent, I know of no other virtue lemon peel possesses, for I never heard of its possessing tonico or any other medicinal property.

But let us look at the question of infusions from another aspect. The dose of most of them is given in the Pharmacopoeia as from 1 to 2 ounces, some 2 ounces. I think the dose is from 2 to 4 ounces. Does anyone nowadays get prescriptions containing infusions where the dose prescribed is even an approximation to that?

Is it not rather the case that the infusion is put at the end of the prescription, as if it were only the vehicle in which to administer the other more active ingredients, and the quantity seems to be of no account?

In a four ounce mixture you may have 2 or 2½ ounces, with teaspoonful doses; in a six ounce mixture you will rarely see more than 4 ounces with dessert-spoonful doses; and in eight ounce mixtures rarely more than six ounces with tablespoonful doses.

The days of large doses are over and gone: the mediæval practice has taken their place, so that the sooner the old primitive weak watery infusions are done away with, and the more potent and useful concentrated infusions officially recognised, the better.

Mr. Brodie produced a number of specimens in the way of roots, barks, and such like, which he had reduced to moderately fine powder by putting through a coffee mill he devoted to that purpose, and also specimens of liquid extracts, concentrated infusions, syrups, etc., as prepared by him, of which liquid extract of oasrars, conc. inf. senega, and liquid extract taraxacum were particularly fine.

The paper was well criticised and a cordial vote of thanks accorded.

Correspondence.

A PHYSIOLOGICAL DISCOVERY IN CONNECTION WITH THE CIRCULATION OF THE BLOOD.

SIR,—The reviewer of my paper on the above subject has evidently only glanced at it; he cannot possibly have read it, as my theory is clearly stated and should be easily comprehended by a competent critic. Ridicule is a very powerful weapon, but before hurling its darts my reviewer would have been wise had he been more truthful or careful in his reading. May I ask him through your columns to quote the page and line of my pamphlet in which I state that I have had under examination the livers of a sheep? I fail to find any such passage. He is pleased to say that "for want of a familiarity with anatomical and physiological terms the description of the observations on which the author finds his views is, as yet, incapable of being interpreted, and so it is impossible to criticise." Am I to regard this as a confession of ignorance on his part? Or does he take exception to the terms I have employed? I shall be glad to be corrected where I have erred. Ne sutor ultra crepidam — I beg pardon — Ne sutor supra crepidam. The cobbler, if a cobbler, should undoubtedly stick to his last, it is better to be even a respectable cobbler than a jack of all trades and master of none, but master minds have in all ages been furnished with original ideas, and the world is certainly richer for the discoveries of such men as Galileo, Harvey, Newton, Faraday, and numerous others whose theories have not always been favourably received by the so-called scientists of their day and generation. In justice to me I ask for the insertion of this letter in your next issue.

Grantham. F. D. FISHER.

* * * In reference to Mr. Fisher's complaint that he has been misquoted, the Reviewer writes that on comparing his review with the original paper, he finds that he has quoted "the livers of a sheep," instead of "the livers of sheep," and much regrets that he had inadvertently done Mr. Fisher that injustice. [Ed.—Pharm. Journ.]

AQUA CAMPHORATA.

SIR,—I have long considered sq. camph. a very unsatisfactory preparation, both on account of its rule-of-thumb mode of solution and consequent variation in strength. Would it not be an improvement to make it by adding a definite quantity of camphorated spirit to distilled water and shaking till dissolved? I am aware this is very "low game," but our "visitors" might consider it even.

Scarbrough. ALFRED JONES.

The Major Examination.

SIR,—Seeing my suggestion "That the subjects for the Major examination might be taken one or more at a time at the discretion of the candidate" has been favourably received, and hopes expressed that it may be brought before the Council for consideration; I would endeavour to do if all who are interested would signify their assent and willingness to co-operate by sending me their full names and addresses to be copied upon sheets, (as it would obviously be impracticable to obtain the autograph signatures on the sheets to be presented to the Council) and also any suggestion or reason that would carry weight in favour of the concession.

St. Austell. S. C. FREDERICK MICHELL.

Answers to Correspondents.

THE DISCOVERY OF OXYGEN.

(Concluded from page 524.)

ANTOINE LAURENT LAVOISIER.

Lavoisier was born at Paris on August 26, 1743. He was the son of a lawyer who belonged to a wealthy family, and was educated at the College Mazarin, where he studied, amongst other subjects, botany, chemistry, geology, mathematics, and mineralogy. Though he qualified for the legal profession his inclinations led him to devote himself later to science. In 1768, he was elected a member of the Academy of Sciences, and as director of that august body he fought vainly for its existence during the French Revolution. Unfortunately, also, he incurred the enmity of Marat by contradicting the assertion of the latter, that an absurd essay he had published on the nature of fire had received the approval of the Academy.

Early in 1768, Lavoisier entered the Forme générale, or body of financiers which rented the right of collecting the indirect taxes throughout France, as assistant. He became a formier général in 1779, and occupied that position, discharging his trust honourably, until March 20, 1791, when the National Assembly suppressed the institution. He was also appointed to superintend various industries, such as the manufacture of tobacco and gunpowder, and as secretary of the Committee of Agriculture became interested in the cultivation of economic plants, the establishment of experimental farms, etc. About 1787, as a member of the Provincial Assembly of the Orléanais, he was engaged in introducing schemes for founding banks and insurance societies, and forming canals, whilst two years later he was elected a member of the Commune of Paris, and in 1790 was sent to the States-General.

The strictest integrity and most honourable distinctions failed, however, to protect the distinguished chemist during that period of acute national disturbance known as the Reign of Terror. On November 28, 1793, he was arrested by order of the Convention and tried on the charge of having, as formier général, furnished water and other ingredients, detrimental to the health of the citizens, to tobacco. He was condemned to death, and a memorial in his favour presented to the judges was rejected by the president of the tribunal, Collinhal, with the remark that the Republic had no need of men of science, and justice must take its course.

(La République n’a pas besoin de savants; il faut que la justice suive son cours). On May 8, 1794, therefore, he suffered death on the guillotine within twenty-four hours of receiving sentence, and at the age of barely fifty-one years.

In 1765, Lavoisier contributed his first paper to the Academy of Sciences, explaining in it why plaster of paris sets when mixed with water, and cannot be re-hydrated. In the course of the same year he turned his attention to the artificial lighting of towns, and was awarded a prize by the Academy for an essay on the subject. He concluded in 1770 that water could not be converted into “earth,” after heating some in a closed vessel for 101 days, and it is noteworthy that he employed the balance in this investigation. Two years later he began to investigate the phenomena of combustion, and observed that when sulphur and phosphorus are burned an increase in weight takes place. He next examined the kind of air given off during respiration, combustion, and fermentation, confirming the results of Black, who showed (1755) that it is a peculiar constituent of carbonated alkalies, differing essentially from common air, and named it “fixed air.” Lavoisier went further, however, and proved that it is an oxide of carbon, being thus the first to properly explain its chemical nature. In 1772, the year that Lavoisier began his investigation of the theory of combustion, Rutherford had made the important discovery that atmospheric air naturally contains a substance which is incapable of supporting combustion or respiration, and to this he applied the name “nitrogen.” Priestley about the same time arrived at a similar conclusion, differing only in that he imagined the gas to be air rendered impure by the addition of phlogiston. He named it, therefore, phlogistated air. Lavoisier also experimented with this gas, isolating it by burning phosphorus in a confined volume of air, and found that it constituted four-fifths of common air. He was the first to regard it as a simple body, and called it first “moufette atmosphérique,” and later “azote.” The information thus obtained, added to the facts disclosed in experimenting on the calcination of lead and tin, enabled him to arrive at the conclusion that air consists of two different elastic fluids. This was in 1774, but it was not until the following year that he distinctly mentioned oxygen gas (l’air éminemment respir-
able, pur, or vital), and showed that the whole theory of combustion was clear to him. Finally, the discovery of the compound nature of water by Cavendish, in 1783, enabled Lavoisier to complete his theory of combustion and prove conclusively by experiments that the phlogiston theory was incorrect, the outcome of his work being that the science of chemistry was placed on its true basis.

Lavoisier's Work on Oxygen.

During Priestley's researches he found that when lead or tin was calcined in a closed vessel absorption of air took place, but, a confirmed phlogistonist, he failed to connect this phenomenon with the augmentation of weight that occurred in the heated substance. Lavoisier, during the same year (1772), noted the same fact on burning phosphorus and sulphur, and, in a communication to the Academy of Sciences, expressed the opinion that red precipitate, as also in the calculation of metals, the increase of weight was due to the absorption of air, which was again liberated when the metallic calces formed were reduced with charcoal. It will thus be seen that, whilst both investigators were simultaneously progressing in the same direction, the French chemist was quick to perceive the true bearing of his observations, whilst Priestley made no attempt to explain why the air diminished when combustion took place in a confined space.

Prior to 1773, Scheele had obtained oxygen (fire-air) from various substances, but the published account of his experiments did not appear until 1777, being anticipated by Priestley's account of the same discovery, which appeared about two years earlier, though Priestley did not isolate his "dephlogisticated air" and recognise it as a distinct substance until August, 1774. Visiting Paris during October of the same year, Priestley mentioned at Lavoisier's table, when "most of the philosophical people of the city were present," that he had obtained from red precipitate and red lead "a kind of air in which a candle burned much better than in common air." Lavoisier repeated Priestley's experiments, and rightly concluded that the "dephlogisticated air" of the latter was identical with that constituent of air which he had found that metals and other bodies absorb on burning. Proceeding with his investigations, he observed that acids were produced when the majority of substances examined combined with the new gas, which he accordingly renamed "oxygène" (lité, sour, and yeuvde, I produce). Subsequently, in his "Éléments de Chimie," published in 1782, he claimed that he had discovered the gas independently.

Though this claim cannot be substantiated, and does not at all redound to the credit of Lavoisier, it is not so clear that he was not the first to arrive at the conclusion that the newly discovered gas was the constituent of the atmosphere essential to combustion, respiration, and the calcination of metals. He was undoubtedly much more capable than Priestley of appreciating the nature of the phenomena in which the gas plays a part. Yet, in a memoir on the calcination of lead and tin, published in November, 1774, though he expressed the opinion that air consists of two gases, one only of which was capable of supporting combustion and respiration, he did not express any decided view as to their nature. In the experiments he describey, when lead and tin were heated in a closed flask they did not change in weight; but when the neck of the flask was broken, air rushed in and the weight was increased by a portion of the air being taken up by the molten metal. The residual air in the flask was noted to be different from common air and also from fixed carbon.

The first distinct recognition by Lavoisier of the fact that the gas obtained on heating red precipitate is the same as the constituent of atmospheric air which supports combustion, is found in a paper read near the latter part of 1775. During the same year he first put forward his views on the nature of combustion and respiration, in the form of a hypothesis. Scheele's results, as already mentioned, were published in 1777, and in the following year Lavoisier first mentioned the gas as "oxygène," or the acidifying principle. In a second memoir on the nature of combustion and respiration, published by the Academy in 1783, Lavoisier definitely denied the existence of any "principle of combustibility," and stated that carbon, sulphur, the metals, etc., are simple substances which on combustion enter into combination with oxygen.

The Composition of Water.

During the year 1781, Cavendish had determined that 100 volumes of common air contain 20.9 volumes of pure air (oxygen), and was led by some observations of Priestley and by the subproducts produced by exploding definite volumes of inflammable air (hydrogen) and common air. Water was found to be produced, and in a paper published in 1784 Cavendish stated that "423 measures of inflammable air are nearly sufficient to phlogisticate 1000 of common air," or "almost all the inflammable air and about one-fifth of the common air are turned into pure water." He also identified the portion of the common air that was absorbed with Priestley's dephlogisticated air, and showed that when one volume of this combined with two of inflammable air, no only product was pure water. Like Priestley, however, he allowed the phlogiston hypothesis to warp his ideas, and probably never clearly realised that water is a chemical compound of the two elementary gases, though James Watt, in 1783, had expressed the opinion that water was composed of dephlogisticated and inflammable air.

The particulars concerning Cavendish's experiments becoming fully known, they were repeated, and the results obtained confirmed by Lavoisier and Lepaute. In the apparatus employed by Lavoisier, the water contained in the vessel was allowed to drop slowly into the tube e d, and then flowed into the gun barrel f, which was heated to redness in the furnace. As the water was decomposed in the gun-barrel, the oxygen united with the heated iron, and the hydrogen passed through the worm s, where
any undecomposed steam accompanying it was condensed. Finally, the hydrogen was collected and measured in the glass bell jar 5, standing in a pneumatic trough. As a result of this experiment, it was found that 28.9 volumes of hydrogen entered into combination with 12 volumes of oxygen.

Lavoisier's Apparatus for Decomposing Water.

Lavoisier was now able to explain that the solution of metals in acids, no less than their combustion, is due to the oxygen taken up, in the first case from the water present, as in the other from air. He regarded the solution of a metal in a dilute acid as a two-fold reaction; first, the metal decomposed the water, liberating the hydrogen, and combined with the oxygen to form a calx; secondly, this calx combined with the acid to form a salt soluble in water. This explanation was entirely opposed to the ideas current at the time it was propounded, but gradually replaced the latter and was generally accepted until quite recent years.

The discovery of the compound nature of water has been claimed for Lavoisier, and it would certainly appear that in 1774 he was persuaded that the combustion of hydrogen consisted in the fixation of some portion of atmospheric air, and suggested that this would probably be accompanied by an increase in weight. But the most that can fairly be ascribed to him is priority in giving the true explanation of the experimental results recorded by Cavendish and confirmed by himself. The true position of affairs has been stated as follows:—Cavendish first ascertained the facts, Watt first argued from these facts concerning the true nature of water, and Lavoisier first clearly recognised the compound nature of the liquid, and determined exactly the proportional amount of its components.

Overthrow of the Phlogiston Theory.

These two facts, then, the discovery of oxygen by Scheele and Priestley, and the determination of the composition of water by Cavendish, served Lavoisier as his chief weapons in completing the downfall of the doctrine of phlogiston, the absurdity of which is pointed out in the following passage:—"Chemists have made a vague principle of phlogiston which is not strictly defined, and in consequence accommodates itself to every explanation into which it is pressed. Sometimes this principle is heavy, and sometimes it is not; sometimes it is free fire, and sometimes it is fire combined with the earthly element; some-

* Cavendish's proportions of 2 of hydrogen to 1 of oxygen were confirmed, however, by the more exact experiments of Gay-Lussac and Humboldt, in 1805.
but one kind of matter; showed how such simple bodies unite to form compounds; defined acids, oxides, salts, etc.; and thus formed the basis of modern chemistry. In addition, still absorbing and giving a more extended value to the ideas of others, he supported Morveau's suggested system of chemical nomenclature, which contained the germ of that now in general use, and, aided by Berthollet and Fourcroy, adapted it to the new theory.

Though prematurely cut off at the height of his activity, Lavoisier was fortunate in seeing his explanations accepted almost generally. Scheele has been described by Wurtz as dying an energetic defender of the word “phlogiston,” though no longer a fully convinced partisan of the theory connected with it; Cavendish’s last publication was an elaborate and ingenious defence of that theory, but he is said to have subsequently withdrawn his opposition to the new ideas without actually surrendering; and of critics of note, perhaps Priestley alone never ceased to oppose antiphlogistic principles, and carried his belief in the hypothesis that had led him so far astray to the end. The triumph of Lavoisier’s work, then, was complete. He found chemists exclusively occupied with the outward appearance of facts—the qualitative side of phenomena—and inaugurated what is now recognised as the only true method of chemical research, based on quantitative work. Near the close of the seventeenth century, Robert Boyle—by contesting “the doctrines of the four elements, and the three chemical principles of mixed bodies,” and by clearly distinguishing between mixtures and true chemical combinations—inaugurated the birth of scientific chemistry as distinguished from alchemy. In like manner, a hundred years later, Lavoisier founded a remodelled and thoroughly scientific theory of chemistry, by the “happy co-ordination of the apparently isolated and vaguely expressed items of knowledge of his day into a harmonious and perceptive whole.”

THE DETERMINATION OF ACONITINE.

BY JOHN C. UMMY.

I was engaged for some nine months in 1890-91 in an investigation of the alkaloidal constituents of Aconitum napellus, in the Research Laboratory of the Pharmaceutical Society of Great Britain, and it was suggested by the Director, on the completion of that work, that I should continue, independently, my work on this subject, more especially as regards the determination of crystalline aconitine in galenical preparations, with a view to their standardisation.

The constitution of aconitine having been now more clearly defined, its determination, based on such knowledge, has been rendered possible by any accurate process in which the proportion of acetic acid resulting by its decomposition (either by heating to a high temperature or by hydrolysis) is ascertained.

The latter method of decomposition has been adopted, since the benzoic acid produced under those conditions becomes aconite itself and benzaconine (existing as such in the plant or converted into such in the manufacture of galenical preparations), does not interfere with the determination.

I have devised a process which depends on the decomposition of aconitine by complete hydrolysis into aconite, acetic and benzoic acids, the former of which acids is derived from the crystalline aconitine, the latter from the intermediate product, benzaconine, formed during the hydrolysis in the case of pure aconitine or in the case of commercial alkaloid or total alkaloidal residues from that body, as well as any benzaconine present originally as such.

It is obvious that the presence of any alkaloid other than aconitine, yielding acetic acid on hydrolysis, the discovery of which has not hitherto been announced, would slightly modify the result based on the determination of this acid, but such body, if present, can only exist in very small proportion in Aconitum napellus.

The process may be briefly described as follows:—

A definite weight of alkaloid or total alkaloidal residue is completely hydrolysed by heating on a water bath for two hours, in a flask fitted with a reflux condenser, with a certain volume of alcoholic solution of a caustic alkali. The acetic and benzoic acids thus produced combine with the alkali present, the amount of which has entered into combination being determined by difference by titration of the uncombined alkali with a volumetric solution of acid.

The solution after titration is again made markedly alkaline, and the alcohol dissipated on a water bath. To this is then added sufficient excess of hydrochloric acid to liberate the whole of the benzoic acid, which is removed by successive washings with ether. The benzoic acid is then weighed and the amount of solution of alkali which was required for its neutralisation in the first part of the process calculated. On deducting this amount from that of the total alkali required for neutralisation of the acetic and benzoic acids formed by hydrolysis, the amount required for neutralising the acetic acid formed, and thus the amount of crystalline aconitine present is determined.

I am engaged in adapting this process to the assay of the root and leaves of Aconitum napellus, with a view to the standardisation of their galenical preparations, but cannot claim to have been until the definite dose of both pure crystalline aconitine and benzaconine are therapeutically determined.

I refrain, therefore, at present from detailing any of the results obtained in the experiments which I have carried out with commercial aconitine and total alkaloids obtained from the root, as well as the alkaloidal residue obtained by suitable treatment from the various galenical preparations. It may be observed, however, that calculating from either of the two formulae put forward for aconitine, and at present under discussion, the amount of acetic acid produced by hydrolysis is practically identical, viz., 9.30 and 9.27 per cent., respectively, and final acceptance of either as correct will only affect in the slightest degree the determination of aconitine by this process.

The amount of benzaconine present as such, in a total alkaloidal residue, is obviously determined by deducting from the total benzoic acid, liberated on hydrolysis from a definite weight of such residue, that proportion derived from the aconitine originally present, as shown by calculation from the acetic acid produced.
NEW YORK, SATURDAY, APRIL 6, 1895.

THE PHARMACEUTICAL JOURNAL.
FIFTY-FOURTH YEAR OF PUBLICATION.

EDITORIAL.

Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

Advertising Department.

Advertisements and remittances must be sent to "Street Brothers," 8, Serle Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased, and to whom Cheques and money orders should be made payable.

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary—Mr. Richard Bremridge, 17, Bloomsbury Square, London, W.C.

THE COUNCIL MEETING.

At the meeting last Wednesday the President announced that a communication had been received from Sir Henry Roscoe, as Chairman of the Weights and Measures Committee, asking him to give evidence on the subject. The date fixed for that purpose was found inconvenient, and consequently his attendance at the Committee would now be deferred until after Easter.

The additions to the Society comprised three pharmaceutical chemists and one chemist and druggist as members, forty-six associates, and nineteen students.

Among the nominees for election on the Council who have signified their willingness to accept office are the names of Messrs. Batson, Campkin, Corder, Savory, and Wills. Mr. Thomas Greenish does not intend to offer himself for re-election. The present auditors have again been nominated, and have expressed their willingness to accept office if elected.

The report of the Finance Committee showed that the receipts during the past month have been considerable, both to the general funds of the Society and to the Benevolent Fund. The donation account has been augmented by donations of one hundred pounds, and fifty pounds from the two sons of Mr. Charles Maw, and a legacy of one hundred pounds left by the late Mr. Hooper, so that the balance now amounts to about four hundred pounds for investment. In moving the adoption of the report the President mentioned that Madame Ferrin, of Moscow, had informed him of her intention to continue the subscription of her late husband to the Benevolent Fund.

On the recommendation of the Benevolent Fund Committee, one grant of twenty pounds, one of fifteen pounds, one of ten pounds, and one of six pounds were ordered to be paid. The Vice-President again drew attention to the case of Mary Margaret Lewis, a candidate for election to the girls’ school, at Ashford, with the object of reminding members of the Society that this would be her last chance.

The report of the Library, etc., Committee, gave the usual statements of the attendance in the Library and Museum, the donations to Library and Museum, etc. It also recommended the carrying out of some decorative work in the Society’s House, and better provision for the ventilation of some of the rooms.

Letters from the Sheffield Pharmaceutical and Chemical Society were read, thanking the Council for the grant recently made, and for the Calendar and Register for 1895. A letter from Mr. C. Thompson, the local secretary in Birmingham, stated that at a meeting of members and associates of the Society, held on March 29, it was resolved to request the Council to take immediate steps to remedy the evils resulting from co-operative trading. This communication was referred to the Law and Parliamentary Committee for consideration.

The auditor’s report was presented, and after the report of the General Purposes Committee, dealing with legal matters, had been considered in committee, proceedings were afterwards ordered to be taken in several of the cases reported upon.

The Council then adjourned until the second Wednesday in May.

A THEORY OF ELECTROLYSIS.

The Electrical Review refers to the fact that in the introduction to his work on electro-chemistry, Ostwald remarks that to a philosophic mind nothing is more fruitful than the historical study of a science, and points out that this statement is strikingly true of the science of electrolysis, to whose development Ostwald has contributed so much. Bucherer, it is stated, has recently engaged his attention upon this, and has emphasized the fact that of all conceptions that of the first and second laws of thermo-dynamics have done most in clarifying our views and in paving the way for new discoveries. The old preconceived notions, however, still exercise their vicious influence. Bucherer has endeavoured to formulate a new theory which shall be innocent of the inconsistencies which surround and poison the generally accepted views. He expounds this theory in the Electrical World, and takes as the basis the mass law which in the thermodynamic treatment of chemical reactions has played so important a part. From the standpoint of the mass law, chemical equilibria are viewed as dynamical equilibria. Bucherer regards the potential difference between a metal and its solution as directly due to the relation of the partial pressure of the metallic vapour with which it participates in the equilibrium and
the sublimation pressure of the immersed metal. This, remarks our contemporary, does not accord with the modern view of electrolysis as represented by Nernst's theory of a solution tension. Bucherer has obviously followed the reasoning used by Ostwald, the difference being that he deals with the partial pressures of the metallic vapour and the molecular non-metallic constituents of a solution, where Ostwald and Nernst consider the osmotic pressures. Bucherer's theory, however, leads to much the same results as the generally accepted theory in spite of the fact that, according to one of them, the number of ions increases by dilution, and to the other it decreases. He will be certain to attract much attention by his new theory, but, the commentator observes, it is another matter whether it will stand searching criticism.

EVENING MEETING IN EDINBURGH.

We are requested by Mr. W. A. H. Naylor to point out a curious error in the otherwise excellent paper by Mr. Maben, which appeared in last week's Journal (p. 846) Mr. Maben, referring to Mr. Naylor's article in the Journal for March 9, states that the latter there recommended that potent remedies should have a strength of 10 grains in 100 minims. This is not correct, however, as "x grains" does not necessarily represent "10 grains," but must vary according to the standard adopted. In the sentence referred to by Mr. Maben, "x" represents an unknown weight, and Mr. Naylor's intention was that, for the convenience of prescribers, 10 minims of the respective liquors should contain several an integral quantity by weight of the potent substances, arsenic, strychnine, etc. Whether the proportion should be 1 or more grains in the 100 minims is left to the revisers of the Pharmacopoeia to decide.

REGISTRATION UNDER THE MEDICAL ACTS.

The Medical Register for 1895, which we have just received from the Registrar of the General Medical Council, shows an increasing tendency to bulkiness, since it now occupies fourteen hundred and forty pages. According to Table E, the total number of persons registered in the local registers or England, Scotland, and Ireland, since 1858, is 54,249, of whom 32,637 yet remain in those registers—19,449 in England, 8389 in Scotland, and 4749 in Ireland. Table F shows that 1428 persons were added to the Register in 1894, 71 were restored, and 504 were removed for various reasons. In 1893, 1579 names were added to the Register, that being the highest number on record, so that it would now appear that the numbers are beginning to decline. The new Medical Students' Register gives the number of students registered during 1894 as 989 in England, 485 in Scotland, and 197 in Ireland. The numbers in 1893 were 1007, 560, and 180 respectively. The total number registered during 1894 (1671) is identical with that for 1892, but less than that for 1893 (1747), and considerably less than that for 1891 (2405), which was the highest on record. The Dentists' Register, which we have received at the same time as the above, gives the total of dentists registered as 4901. Of these 1363 are licentiates in dental surgery of the English, Scottish, and Irish colleges, and 3511 are in bond-fide practice of dentistry, in addition to 27 possessing American diplomas.

THE MAJOR EXAMINATION.

In the discussion on this subject it will be observed that one of the contributors suggests that it is sufficiently important to deserve editorial comment. It may be pointed out, however, that whilst there is no objection to the columns of the Journal being open to discuss the matter, it is not desirable that the official organ should commit itself to a decided opinion upon the matter, which is essentially one to be considered by the administrative body of the Society, and may possibly be regarded as a question of principle rather than of mere expediency, though the latter seems to be the opinion of several of our correspondents. If such a change as is suggested should be effected at any time, there is little doubt that the standard of efficiency would necessarily be raised considerably in all the subjects, and candidates might find that after all, the present arrangement is the more convenient one. At any rate, those desiring to proceed further in the matter can take advantage of Mr. Michell's offer in last week's Journal (p. 856), and it will then be easy to get a definite opinion upon the proposition.

MODERN TELEGRAPHY.

The Daily News of Thursday last describes a species of telegraphic communication which, though not new to the scientific world, may fairly be described as marvellous. The cable between Oban and the Isle of Mull being out of order, messages have been transmitted across the water, no connecting apparatus being employed, but the desired result has been effected by means of the well-known phenomenon of induction. A wire has been erected on the mainland opposite to and parallel with a portion of the telegraph line on the island, and the message which it is desired to communicate to Mull is transmitted over the wire on the mainland in the ordinary way. The signals thus transmitted pass at the same time over the parallel line in the Isle of Mull, and telegraphic operators there read them by means of a telephone. This is believed to be the first time the method has been turned to account in the practical, everyday work of telegraphy, the result being due to Mr. Paternoster and his assistants on the Engineering Staff of the Post Office.
Transactions of the Pharmaceutical Society of Great Britain.

MEETING OF THE COUNCIL.

Wednesday, April 3, 1895.

Present:

M. R. MICHAEL CANTHOE, PRESIDENT,
MR. WILLIAM GOWEN CROSS, VICE-PRESIDENT,
Messrs. Allen, Atkins, Bottle, Goostling, Hampson, Harrison, Hiles, Johnston, Martin, Martindale, News-
holme, Southall, Storrar, Warren, and Young.

The minutes of the previous meeting were read and
confirmed.

THE WEIGHTS AND MEASURES ACT.

The President said a communication had been
received from Sir H. Roscoe, Chairman of the Weights
and Measures Committee, asking him (the President)
give evidence, and fixing a day for his attendance,
but that day was afterwards found to be inconvenient,
so that his evidence would now have to be deferred
until after Easter.

ELECTION OF MEMBERS.

Pharmaceutical Chemists.

The following having passed the Major examina-
tion, and tendered their subscriptions for the current
year, were elected "Members" of the Society:

McKenzies, Thomas ...............Golspie.
Pearce, John Hammond ...........Horwich.
Perkins, Catherine Susan ..........Birmingham.

Chemist and Druggist.

The following who was in business before August 1,
1895, having tendered his subscription for the current
year, was elected a "Member" of the Society:

Dennis, James Edward ............Nottingham.

ELECTION OF ASSOCIATES IN BUSINESS.

The following having passed their respective ex-
aminations, being in business on their own account, and
having tendered their subscriptions for the current
year, were elected "Associates in Business" of the
Society:

Minor.

Allen, James ..................Bristol.
Andrews, Charles Russell ........Wappingers Falls.
Ayre, George Martin ............Perth.
Ball, Henry Simpson .............Nottingham.
Blankiron, Jeremy ...............Edinburgh.
Chambers, John Wm. Parsons ......Nottingham.
Coates, Frederick Charles .......Nottingham.
Cripps, Ernest Charles ..........Berkhamsted.
Dand, Arthur ...................Liverpool.
Ferguson, Joseph Johnston ......Leytonstone.
Green, Walter Joseph ............Trowbridge.
Groth, Marchius Gustave B. ....Hartlepool.
Hampton, George ................Reading.
Harris, George Robert ...........Eastbourne.
Hopley, John Henry .............Chester.
Kay, William ...................Cumnock.
Kaye, Alexander .................Perth.
Kerr, Hugh .....................Dalbeattie.
Langbourne, Walter Charles ....Stockport.
McKenzie, James ..........Singapore.
McNiven, James .................Falkirk.
Scott, Joseph .................Barrow-in-Furness.
Swininglehurst, Joelah ........Nelson.
Temple, Charles Herbert ........Eastbourne.
Tuner, William .................Chester.
Urguhart, Robert ...............Aberdeen.
Widdowson, Reuben .............Nottingham.
Wilkinson, William Franklin ....Blackpool.
Williams, John Wynn ..........Mold.

Modified.

Adam, Thomas ..................Glasgow.
Ashby, William .................Nottingham.
Bowman, John ..................Leith.

ELECTION OF ASSOCIATES.

The following having passed the Minor examina-
tion, and tendered their subscriptions for the current
year, were elected "Associates" of the Society:

Bainbridge, John ..............Kirkby Stephen.
Brown, William James ..........Dover.
Dobson, John ..................Tongueland.
Duncan, Charles Tocher .......Tandem.
Fairweather, James Young ......Forfar.
Furnival, Charles Edward ....Lelorest.
Innes, James ..................Turriff.
Macintosh, Robert .............Grantown.
Morcombe, Joseph ..............Pembroke Dock.
Shepherd, Joseph Henry .......Derby.
Simpson, Herbert ...............West Hartlepool.
Tattersall, John ...............London.
Turner, William Henry ........Workop.

ELECTION OF STUDENTS.

The following having passed the First examination,
and tendered their subscriptions for the current
year, were elected "Students" of the Society:

Broadbank, Albert Samuel ....Stockton-on-Tees.
Burrett, Frank B. S. ...........London.
Dexter, Bertie ..................Nottingham.
Dodridge, William James ......Woolstole.
Edwards, Evan David..........Rhayader.
Heden, Joseph Henry ............Kineton.
Hill, Harry Ernest .............London.
Hogg, Walter ..................Ulverston.
Horsley, Percy James ..........Weymouth.
Jones, Robert Bryan ..........Llanfyllin.
Lane, Herbert ..................Princes Risborough.
Lewis, Moritz Avon ............Pensance.
Martin, Walter E. .............Beccles.
Oliver, John ..................Bilston.
Owen, John Edmund .............Abergele.
Pratt, Charles Andrews .......Chichester.
Sinclair, James .................Aberdeen.
Waddingham, George Albert Batley.

Several persons were restored to their former status
in the Society upon payment of the current year's
subscription and a restoration fee of one shilling.

NOMINATIONS FOR COUNCIL AND AUDITORS.

The Secretary reported that he had received
twenty-one nominations to fill the fourteen vacant
seats on the Council, and that the following eighteen
had declared their willingness to accept office if
elected:

Allen, Charles Bowen, 20, High Road, Kilburn, N.W.
Atkins, Samuel Ralph, Market Place, Salisbury.
Bateson, Thomas, 23, Stricklandgate, Kendal.
Bottle, Alexander, 37, Towhall Street, Dyer.
Campkin, Algernon Sydney, 11, Ross Crescent, Cambridge.
Carteigh, Michael, 180, New Bond Street, W.
Corder, Octavius, 51, London Street, Norwich.
Grose, Nicholas Male, 8, Temple Street, Swansea.
Hampson, Robert, Knole Paddock, Sevenoaks.
Harrison, John, 33, Bridge Street, Sunderland.
Hills, Walter, 225, Oxford Street, W.
Martin, Charles, 10, New Cavendish Street, W.
Newsholme, G. T. W., 74, Market Place, Sheffield.
Savory, Arthur Ledsam, 143, New Bond Street, W.
Southall, Alfred, 17, Bull Street, Birmingham.
Wills, George Sampson V., “Southwood,” Graham Road, South Croydon.
Young, John Rymer, 42, Sankay Street, Warrington.
The following three nominees had not expressed their willingness to accept office:
Greenish, Thomas, 20, New Street, Dorset Square, N.W.
Powell, Thomas Henry, 116, Denmark Hill, S.E.
Robinson, William Prior, 17, The Pavement, Clapham Common, S.W.

AUDITORS.
The Secretary also reported that he had received the following five nominations to fill the office of auditor, and that all the nominees had expressed their willingness to accept office if elected:
Butt, Edward Northway, 77, Hamilton Terrace, N.W.
Lester, Frank Harwood, 80, Bartholomew Close, E.C.
Stacey, Samuel Lloyd, 500, High Holborn, W.C.
Umney, Charles, 50, Southwark Street, S.E.
Yates, Francis, 64, Park Street, Southwark, S.E.

REPORT OF THE FINANCE COMMITTEE.
The Secretary read the report of this Committee, which recommended the payment of various accounts.
The President (as Chairman of the Committee) moved the adoption of the report. He said the receipts had been considerable during the month, mostly arising from subscriptions and examination fees. The payments were of the usual character. On the Benevolent Fund account a fair amount of subscriptions had been received—viz., £304; and on the Donation account there was now a balance of about £400 in hand, it having been augmented by donations from the two sons of Mr. Charles Maw (one of 100 guineas, and the other of 50 guineas); and the legacy of £100 left by the late Mr. Hooper had also been received. Looking at the present price of Consols it was not considered desirable to invest this balance at present, but rather to wait a little in the hope that a suitable investment in ground rents might offer. The amount of grants made last month was smaller than usual, but there would be no doubt more calls of that nature coming forward, and it was not proposed to invest any of the current balance from subscriptions. As he had said before, he considered it the duty of the Council to distribute the contributions received during the year to deserving cases, and not to invest the subscriptions for the benefit of posterity. He might add that he had received a very nice letter from Madame Ferrein, the widow of their late distinguished corre-

sponding member at Moscow, saying that on looking through her husband’s papers she found a receipt from the Pharmaceutical Society for £1 subscription to the Benevolent Fund, and in accordance with what she knew would have been his wish, she should continue to contribute the like amount annually as long as she lived.

The report and recommendations were adopted.

BENEVOLENT FUND COMMITTEE.
The report of this Committee recommended the following grants:
£8 to a registered chemist and druggist (64) who is unable to support himself. (Stoke Newington.)
£20 to a registered chemist and druggist (70) till lately in business on his own account, but now without means. He has a sister of seventy-two dependent on him. (Clapham.)
£15 to the widow (51) of a member who had himself received six grants (totaling £85). Applicant is suffering from an incurable spinal complaint. (Harrogate.)
£10 to the widow (60) of a chemist and druggist who had grants of £10 in 1890 and 1891, and died in that year. (Camden Town.)
One case was deferred, and two were not entertained.

The Vice-President in moving the adoption of this report said its chief feature was the recommendation of a grant to a poor old applicant, who had lived nearly half a century in the same place, and had made a sufficient sum by year by year to keep a respectable appearance, and honestly to pay his way, but the pressure of competition and other circumstances had led to his asking for that temporary relief which he felt sure they all would gladly vote as a fit and proper means of distributing the Benevolent Fund. For himself he was glad that they were in a position to make grants in such deserving cases. Whilst speaking, he also desired again to direct attention to the case of Mary Margaret Lewis, a candidate for the girls’ school at Ashford, and to remind local secretaries and others that this would be her last chance. He felt sure that they could not do a better or more substantial service than by educating a girl like this; and he should be glad if he could be the means, by interview or writing, of furthering her interests at this, the last available chance of thus assisting her.

The report was then adopted.

REPORT OF THE LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

Library.
The report of the Librarian was received and included the following particulars:

<table>
<thead>
<tr>
<th>Attendance</th>
<th>Total</th>
<th>Highest</th>
<th>Lowest</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td>Day</td>
<td>432</td>
<td>25</td>
<td>13</td>
<td>18</td>

</tbody>
</table>

Donations to the Library had been announced (Pharm. Journ., March 16, p. 905), and the Com
The Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended that the undermentioned works be purchased:
- Chambers' Mathematical Tables.
- Nernst's Theoretical Chemistry.

The report of the Curator had been received, and included the following particulars:

<table>
<thead>
<tr>
<th>Month</th>
<th>Morning</th>
<th>Afternoon</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td>February</td>
<td>522</td>
<td>40</td>
<td>48</td>
</tr>
</tbody>
</table>

Donations to the Museum had been received (Pharm. Journ., March 16, p. 806), and the Committee had recommended that the usual letters of thanks be sent to the respective donors.

The President, in moving the adoption of the report, said the repairs and cleaning necessary in different parts of the house had been referred to a special sub-committee, which had made a report, including a recommendation for the finishing of the rooms at the top of the house, No. 16, Bloomsbury Square, and the painting of the staircase. That report, however, did not include a matter which was rather serious, viz., the ventilation of the rooms upstairs, which were now to be decorated. Mr. Bottie had called attention to the fact that the system of ventilation introduced when the premises were built had proved, as was often the case, an absolute failure. The Tobin ventilators had been gradually improved upon or altered until there was practically no ventilation at all. He proposed, therefore, to add to the report of the Committee that the Council be authorised to deal with the ventilation of the four upper rooms of No. 16, Bloomsbury Square. The top room of all was very low, but the pitch of the roof was such that it would be easy, if thought desirable, to make an opening in the roof at a comparatively small cost, and to arrange for ventilating that room efficiently.

Mr. Atkins asked what that room was to be used for.

The President said that had not yet been decided.

The resolution for the adoption of the report, with the addition mentioned by the President, was then unanimously agreed to.

Correspondence.

The President said two letters had been received from the Sheffield Pharmaceutical and Chemical Society thanking the Council of this Society for their gift of the Pharmaceutical Calendar and the Register for 1895, and also for their generous grant of £25 for educational work.

Mr. Charles Thompson, the local secretary for Birmingham, wrote to say that at a meeting held on March 29, it was proposed and carried “That this meeting of members and associates of the Pharmaceutical Society, whilst thanking the Council of the Society for the able and vigorous way in which they have recently enforced the Pharmacy Acts, views the development of the branch system of co-operative trading as tending to the gradual destruction of individual pharmacy, and calls upon them to take immediate steps to remedy that evil.”

On the suggestion of the President this was referred to the consideration of the Law and Parliamentary Committee.

Auditors' Report.

This report was laid on the table as usual.

General Purposes Committee.

The report of this Committee, which dealt with legal matters, was read and considered in Committee.

On resuming, the report and recommendations were adopted, and a special resolution passed authorising the Registrar to take proceedings against the persons named. It was also resolved that the Registrar should be authorised to remove the name of John Blair Connell from the list of persons who have passed the Society’s First Examination.

The Council Meeting in May.

It was decided that the Council meeting in May should be held on the second Wednesday in the month.

Evening Meeting in Edinburgh.
Friday, March 22, 1895.

Mr. J. Laidlaw Ering in the Chair.

(Continued from page 852.)

Note on Chloroform.

By D. Rainy Brown.

I would recommend that the properties and tests for chloroform be stated somewhat as follows in the new edition of the Pharmacopoeia:

**Chloroform, CHCl₃.**

A colourless mobile liquid of sweet ethereal odour. Sp. gr. not under 1.497 at 15°C. Soluble in all proportions in alcohol and ether and in about 200 times its volume of cold water.

Tests.—1. When distilled, the first 10 per cent. fraction and 15 per cent. residue should be free from colour and foreign odour, and the weight of the 15 per cent. residue, after evaporation at 32°C. till constant, should not exceed 1 in 900,000 parts (by weight).

2. On shaking with 10 per cent. (by vol.) of pure concentrated sulphuric acid for twenty minutes the acid should remain colourless or nearly so, and on diluting with water (3 vols.) the mixture should remain almost colourless and clear and give off only a slight foreign odour.

3. On shaking with an equal volume of zinc iodide and starch soln. (zinc iodide 1 part, starch 3 parts, water 500 parts), no colour should be imparted to the chloroform.

4. On shaking with an equal volume of silver nitrate solution no turbidity should be produced; and lastly

5. A water extract of the chloroform should be neutral to litmus.

It should be left to manufacturers to prepare all definite chemical compounds from whatever raw material and by whatever process they choose; but it is for the pharmacopoeial committee to impose such tests as shall prohibit the sale of any but the purest of those compounds for medicinal purposes.

The B.P. recommends the addition of 1 per cent. of ethyl alcohol to chloroform, but at the same time
limits the sp. gr. to 1.497. This is obviously wrong, as the addition of 1 per cent. of alcohol to pure chloroform reduces the gravity to 1.4854 at 10° C., while the quantity necessary to give a product of 1.4977 sp. gr. is 0.25 per cent.

The addition of so much alcohol as 1 per cent. seems to be unjustifiable. If properly stored and kept out of sunlight, a chloroform of sp. gr. 1.497 can be kept for many years without undergoing decomposition; and the fact that such chloroform has now given satisfaction for over thirty years should be a sufficient argument for retaining the gravity at its present standard. The addition of 1 per cent. of alcohol will prevent decomposition taking place, although the change will occur more slowly than in a chloroform containing 0.25 per cent. It might, however, be advisable to increase the percentage of alcohol in chloroforms which are to be used in countries which have a higher average temperature than our own.

The fractional distillation enables us to detect impurities in chloroform which by the present B.P. methods escape observation.

The sulphuric acid test is a very useful one for the detection of an imperfectly purified chloroform, and its modification is still more delicate, as acid which has acquired little or no colour from the sample under examination often indicates impurity by dilution with water.

The most delicate test for the detection of decomposition in chloroform is the zinc iodide and starch one. By it minute quantities of chlorine, which is the first product of decomposition, can readily be detected, while silver nitrate solution gives no reaction until three times the quantity of chlorine necessary to react with zinc iodide and starch is present. For this reason the zinc iodide and starch test should be adopted, but not to the exclusion of the silver nitrate one, as it indicates the presence of chlorine compounds other than chloroform in samples in the more advanced stage of decomposition when zinc iodide and starch give no reaction.

It has been suggested to employ a solution of syrup of iodide of iron and starch instead of zinc iodide and starch, but I have not found it to be a more delicate reagent.

---

**Note on Aloin.**

BY D. RAINY BROWN.

The B.P. states that aloin is insoluble in ether. I have examined several samples from different sources and found that they are all soluble in pure ether, only slight residues of from 0.7 to 1.3 per cent. ultimately remaining undissolved. The residues in every case were mixtures of organic and inorganic matter. Aloin is, however, only very sparingly soluble both in cold and boiling ether.

---

**Ointments.**

BY PETER BOA.

In introducing the subject of ointments for consideration this evening I shall endeavour—so far as I am in the limited time placed at my disposal for the purpose—indicate the directions in which it appears to me discussion may most profitably be carried.

There are in the British Pharmacopoeia forty-five ointments. About twenty of these I have in the course of a somewhat varied experience never seen dispensed. Of the twenty-five or so which I have seen dispensed some ten have very rarely been required. In my experience, therefore, only about one-third of the official ointments are commonly prescribed, and I learn from my fellow-chemists that my experience in this respect is not exceptional.

It may help us in considering the subject if we can ascertain the reason for the neglect which so many of them receive. I shall take one or two examples and indicate what appears to me to be their defects. Carbolic acid ointment is made with a basis in which the greater part of the acid is insoluble, and consequently crystallises in the ointment. If a prescriber once orders this ointment for any of the purposes for which a carbolised dressing is ordinarily used, I should be surprised if he prescribed it again. Aconitine, atropine, and veratrine ointments are highly poisonous and dangerous, and have largely been replaced by ointments or preparations of cocaine and menthol. Calamine is inferior to oxide of zinc in ointment. Cresote is efficiently replaced by carbolic acid and without smell. Glycerin of subacetate of lead ointment is meant to be soothing, but any soothing effect which the lead may possess is neutralised by the irritating nature of the paraffin basis with which it is combined. Elemi, resin, savin, and turpentine ointments are relics of a style of practice which is now, I am told, in disuse by the best practitioners. Spermaceri and simple ointments are not so much in use as they have been; the benzoin in the former spoiling it for ophthalmic use, and the readiness with which the former goes rancid has brought it into disfavour.

Beginning at the root of the matter, it is obvious that the bases employed in the preparation of the official ointments are not above question. Lard, benzested lard, spermaceri, white wax, yellow wax, almond oil, suet, hard and soft paraffin, are the chief substances used either alone or in combination in their preparation. Adeps lanii is new, and is used only in hemlock ointment. The first requisite for an ointment is a basis perfectly free from rancidity. There is not any difficulty in obtaining lard, yellow wax, suet, almond oil in a sweet condition. Spermaceri and white wax, both freely used in our official ointments, are to my mind always in a state of at least incipient rancidity, and might without lose be omitted from the Pharmacopoeia. Hard and soft paraffin do not become rancid, but they are not always bland, and it is difficult to know when they are or are not so. For suitably chosen ointment purposes, however, they are admirable. Adeps lane promises to be a good basis. It is bland, homogeneous, and owing to the stable nature of cholesterol fats keeps well. Its characteristic stickiness can be toned down by almond oil if blandness be required, or
paraffinum molle if this be not so important. With a variety of materials which we can employ in preparing bases I am not disposed to regard with favour a proposal to establish one common basis. However convenient this would be on the score of simplicity and uniformity, I am strongly of opinion that there should be no suspicion of sacrificing efficiency to uniformity. Efficiency first, and uniformity, if convenient, afterwards, strikes me as the proper order.

There might be a classification of certain ointments as regards strength and basis. Those which contain insoluble and not very potent substances might be of uniform strength, and have, possibly, a paraffin basis; while those with soluble active ingredients like carbolic acid and eucalyptus might be made alike in strength and with a fatty basis. If there be a basis in which the active ingredient is soluble that basis should be chosen for it, unless objectionable in some other way. On a previous occasion I have referred to the method of preparing certain ointments. In all the official ointments the ingredients of which are melted together the directions are to stir till cold. I have shown that in many of them this is unnecessary, and in some objectionable. Briefly, a stirred ointment is more liable to become rancid than one allowed to cool at rest, and in application the latter is stated to be more soothing and protective owing to its not containing air. A trial might be made of this process in one or two of the ointments to which it is applicable.

A basis of some non-fatty substance, which would wash off with water without soap might be useful. Tragacanth, starch, dextrin, and gum acacia, either alone or together, might be employed. Some more compound ointments of the sort now in use should be introduced. The compound ointments at present official are among the most useless in the book. If we are to have formula we may as well have useful ones. Bismuth, cocaine, and menthol are now much used in practice as ingredients in ointments. They might suitably be introduced in formula in the new pharmacopoeia.
For the sake of convenience we may roughly divide them into two groups—

I. Those which yield an aromatic extractive.

II. Those which yield a non-aromatic extractive.

In discussing them individually, three general tests may be laid down by which their claims to insertion in the new B.P. may be estimated, viz., the part they are expected to fulfill in the hands of the physician; the suitability of the menstruum for extracting what is required; and the frequency with which they are demanded, either by the physician or by the public. In connection with the last test, the following, excerpt from Martindale’s ‘Analysis of Twelve Thousand Prescriptions,’ will be useful as a reference, and may fairly be taken as a standard. The other table shows how reduction of time affects the amount of extractive yielded by the infusions. In each case the maximum time mentioned is the B.P. time.

**Note:** The shortening of the time made no difference in the colour or the aroma of the infusions, with the exception of gentian. It is referred to below.

**Aromatic Group.**

_Antihamis._—The drug contains a bitter principle soluble in water and in alcohol, and also a volatile oil. This infusion, like many more of them, is a relic of the age when hot water was the only medium thought of in making a preparation of a herb. It is rarely required, and the use of hot water is objectionable on account of it volatilising a portion of the volatile oil which it is most desirable should be retained. For these reasons its retention can hardly be justified.

_Aurantam._—If there is a desire that this one should be retained, the present formula is quite suitable. The fresh infusion has a nice aroma, but a very bitter taste, and will not keep under ordinary conditions for more than three or four days. If fifteen minims, an average dose, of the tincture be diluted to half an ounce with water and compared with the infusion, it will be found that the former has as good an aroma and wants the nauseously bitter taste. Apparently there is a larger proportion of the bitter principle, aurantiamarin—to which the tonic properties of the peel are attributed, present in the infusion than in the tincture. That, however, might be remedied by altering the strength of the spirit, or the process of making the tincture. As they are at present, the infusion is likely the better tonic, and the tincture the better flavouring agent.

_Aurantii Compositum._—It is not so frequently in demand as the simple infusion, and seems unnecessary, as the orange and lemon peels are both included in the formula for the compound infusion of gentian.

_Buchu._—The infusion might well be reduced to fifteen minutes. As will be seen from the table there is only an extra half grain of extractive per fluid ounce in the half hour’s infusion as compared with the fifteen minutes’ infusion. The colour and aroma of the two are similar. The B.P. orders the leaves to be bruised, but in bruising, say, an ounce of the leaves in a mortar, a portion of them is reduced to a coarse powder before all of them can be said to be sufficiently bruised to meet the Pharmacopoeia requirements, and the strength of the infusion may on that account slightly vary at times. Lucas, in a paper (Ph. Jr. [3], xxiv., 665) read last winter at an evening meeting in London, gave it as his opinion that it would be advantageous to omit the directions for bruising the leaves on account of them, at times, giving a mucilaginous infusion of such viscosity that it is almost impossible to strain it. The infusion mentioned in the table was made with *B. crenulata* leaves, but in order to test the matter more fully, samples of *B. betulina* and *B. serratifolia* leaves were obtained and infusions made with each. To make the test as severe as possible, the leaves were in each case coarsely powdered instead of being merely bruised, but in neither case was there any difficulty in straining the infusion. *B. betulina* and *B. serratifolia* each gave 6½ grains of extractive per fluid ounce of infusion, *B. crenulata* 5½ grains. Of course leaves may vary somewhat with the conditions under which they are grown. In face of the contention, however, that a bland mucilaginous liquid is what the physicians desire, it seems the infusion may as well be omitted as to order it being made with unbruised leaves. An infusion made with unbruised *B. crenulata* leaves gave only 2½ grains of dry extractive per fluid ounce. The colour of the infusion was very pale, and to judge by the aroma it did not contain nearly so much of the volatile oil, which is only to be expected from the position of the oil glands in the leaf. Further, Lucas contended that the infusion made with unbruised leaves did not decompose as soon as that made with bruised leaves. The two infusions shown indicate the very contrary. Both were made five days ago, kept in bottles only partially filled, the corks of which were removed three or four times every day. The infusion of unbruised leaves has gone wrong already, whilst that of bruised leaves is quite satisfactory. Evidently the larger proportion of oil present has a preservative action. It is apparently a case of sacrificing utility for elegance. After a careful consideration of all the points it seems desirable that the infusion should be retained made with bruised leaves, and always made fresh as required.

_Caryophyllt._—The activity of cloves depends almost
entirely on the volatile oil. That being so, and the oil already official, an infusion seems unnecessary. It does not appear to be much in demand.

Cascara.—Here we have as active principles a volatile oil and a bitter principle, cascaraflin. The latter is very sparingly soluble in water or alcohol. Its preparations are commonly used as aromatic and tonic adjuncts to other medicines. Considering these two facts together, it seems as if a strong alcoholic menstruum would be more likely than water to give a preparation more suitable in every way. Half a drachm of the tincture diluted to half an ounce with water has a much better aroma than the infusion. The taste is very much the same, both nauseously bitter. Even if it is retained the time might be reduced to fifteen minutes, as the aroma is quite as good, and there is only half a grain less of extractive in the fluid ounce.

Cassia.—rarely used, and should be omitted.

Gentiana Composite.—This is a very popular preparation, and deservedly so, a fifteen minutes’ infusion gives the same amount of extractive as a half hour’s. The only difference between the two infusions is that the lemon odor is slightly more apparent in the former than in the latter. The odor of the latter is more blended, but not finer. It is most desirable that this infusion should be retained and that it should always be freshly prepared. For fineness of aroma the concentrated preparation is not to be compared with the fresh. No doubt the concentrated preparation can be made to contain the proper amount of extractive and may be as good a tonic, but these are not the only points to be considered.

Lupuli.—This infusion may be classed amongst the seldom used, and it is a question for the committee as to whether it is worth retaining it, seeing there is a tincture official. From the table it will be seen that a fifteen minutes’ infusion gives only half a grain less of extractive per fluid ounce than the half hour and one hour’s infusions. The color and aroma are similar in each case. As an argument against the infusion it may be noted that the active principles of hop are a volatile oil and lupulinic acid. The former is only sparingly soluble in water, the latter insoluble.

Rosa Acidum.—As this preparation is only used as a vehicle for other medicines, a fresh infusion is not really necessary; a fluid extract would meet all the requirements. The fresh infusion has a slightly better aroma, but is not nearly so elegant as a fluid extract prepared by percolation.

Serpentina.—This is another infusion seldom prescribed. Lucas, in the paper already alluded to, suggests that the drug should not be bruised, as some of the starch comes out when the infusion is made with the powder, and that is objectionable when the infusion is prescribed along with tincture of iodine, as it sometimes is. When made with the unbruised drug, however, it only yields half a grain of extractive per fluid ounce. On this account and also because its active principles are soluble in alcohol, either a fluid extract or a tincture is likely to prove a more satisfactory preparation.

Valeriana.—Likewise seldom used, and considered by physicians to be much inferior to the two tinctures. On these grounds it seems superfluous.

NON-AROMATIC GROUP.

Calumba.—This is a popular preparation, but it is very doubtful if a fresh infusion is in any way superior to the tincture or a fluid extract. The principal point is to prevent the starch being taken up by the menstruum. In a fluid extract prepared by percolation, and no heat used at any stage of the process, the conditions of the active principles of the drug are not likely to be in any way different from what they would be in the fresh infusion. The quantity of spirit necessary to preserve it could not interfere with its utility.

Caschewu.—In this drug the most important constituent is catechu-tannic acid, soluble in cold water. Of the other two important constituents quereotrin is sparingly soluble in water, and caschehu is soluble in water, but more so in alcohol. It would naturally be concluded that an infusion would be as efficacious as the tincture, but medical authorities say that it is not so. It certainly is very seldom used, and its omission is not likely to be felt.

Chirata.—It has been argued by some that this infusion when made according to the B.P. directions is superior to the tincture, but the latter seems to be as popular amongst physicians. It is used in the same cases as gentian, to which it is closely allied in its medicinal properties, and as it is not so often required, one preparation of it seems sufficient.

Cinohone Acidum.—The principal arguments against this infusion are the great loss of alkaloids in making it, and the fact that there is an acid solution official which is always constant in strength. It has been shown by Thomson that there is a loss of 20.3 per cent. of total alkaloids and 52.6 per cent. of quinine and cinchonidine. Amongst pharmacists the foregoing is enough to justify the deletion of the present formula.

Cusso.—This has all along been a blot in the Pharmacopeia. Surely the blunder will not be repeated.

Digitalis.—Medical opinion differs a good deal regarding this preparation, but that does not come within the scope of this paper. There is one point in connection with it, however, that deserves a little notice, and that is the variation in the strength of it which some physicians complain so much about. The B.P. directions are foxglove leaves, 20 grains; boiling water, 10 ounces. Now if a parcel of dried leaves been knocked about a good deal in transit, and in handling, some of the leaves will likely be broken up a good deal, and if these are used in making the infusion, the resulting liquid will be somewhat stronger than one made with entire leaves. This has been proved by experiment. An infusion made with entire leaves gave 1:16 grains of extractive per fluid ounce, whilst if the leaves were broken by gently rolling them between the hands the extractive amounted to 1:33 grains per fluid ounce. The difference is not great, but it must be remembered that we are dealing with a powerful drug. A. K. Stewart in a letter on infusions (Ph. J. [3], xxii, 460) expressed the opinion that the leaves were not exhausted by fifteen minutes’infra-
sion, and advocated the time being extended to half an hour. There is no doubt about the leaves being only partially exhausted in fifteen minutes, but the same may be said of every infusion in the Pharmacopoeia. Half an hour's infusion gave an extractive of 1.3 grains per fluid ounce, an increase of .14 grains. Since by breaking the leaves into small pieces an equally strong infusion, so far as extractive is an indication, can be made, it would be a pity to extend the time, all the more so since it is held that the infusion should always be freshly prepared.

_Ergot._—This is another of the seldom used class, and as an aqueous extract is already official and held in high esteem by physicians, it might be deleted.

_Jaborandi._—In the case of a powerful drug like this, which requires to be used with such caution, it is a mistake to have a preparation which may vary somewhat, and as a standardised tincture will likely be official in the new B.P., the infusion ought to be omitted.

_Krameria._—One objection to this infusion is that it soon decomposes, the rhusia-tannic acid being oxidised and rhusia-red deposited. The same takes place in the tincture, but in a less degree. Moreover, it is seldom used, and the tincture being retained would never be missed. It is to be hoped the bark alone will be made official in the new B.P.

_Ouri._—This is more a household remedy than a physician's, and might be omitted, as the amateur doctors do not take the B.P. as their guide in making it.

_Matric._—The Infusion is the only official preparation of the drug, but according to therapeutists, as an internal remedy its properties are not well marked, and consequently it is rarely used. It is for the medicals to say if it should be retained. Pharmacologically there is little to be said against it, except that a quarter of an hour's infusion would do quite as well as half an hour, the extractive being the same in each case.

_Quassia._—Water is no doubt a good exhauster of this drug, but it is difficult to perceive how a fresh infusion is superior to an aqueous fluid extract. The quantity of spirit necessary to preserve it can hardly be objected to. A fluid dram of the concentrated preparation does not usually contain more than fifteen minims of rectified spirit, and when this is diluted to an ounce to form the infusion, the percentage of alcohol is very small. Even when it is used as an injection for thread worm, that proportion of alcohol would not be objectionable.

_Rhei._—In view of the cry against redundancy this preparation, might be omitted, as the tincture serves all the purposes it does and is more stable. Hot water might be objected to on account of the presence of starch in the root. Fifteen minutes gives as good an infusion as half an hour.

_Senega._—This is one of the few popular infusions, but it is a question if its popularity has been built up on the merits of the fresh infusion. The only objection to a fluid extract is that on keeping the senegin splits up into sapogenin. The same decom-

position takes place in the tincture, but no deposit is formed as the sapogenin is soluble in the spirit.

_Senna._—Is rarely used except in making the official mixture senna composita and ought therefore to be included in the formula for it and not given separately.

_Uva Ursi._—This is not often used, but as it is the only official preparation of the drug, and generally used in diseases where spirit is contra-indicated, it should remain. The time, however, might safely be reduced to fifteen minutes, as an hour's infusion does not yield any more extractive.

In conclusion I wish to express my thanks to Dr. Stockman for kindly answering several queries relating to the uses of some of the drugs mentioned.

---

**PILLS.**

_By J. L. Fraser._

The maximum size of pharmacopoeial pills should not exceed 4 grm., and in all cases the excipient which makes the smallest pill is to be preferred. For this reason I would suggest that confection of roses should be deleted as an excipient, with the exception of its use in pil. hydargyri.

As a general rule, syrup would prove the most efficient excipient, both as regards bulk and keeping properties.

It would be well if in every case a definite weight of powdered ingredients plus excipient were made into a definite number of pilles, as in the United States and Continental pharmacopoeias, and the number suitable for a dose given. I think it would be an advantage to have a short introductory note on the class pilule preceding that section in the Pharmacopoeia. This note would give some general details as to the various coatings and other matters, and would serve as a general guide to prescribers and dispensers, so that we would not see one man sending out his pills adherent with licorice powder, another lycopodium, a third French chalk, and so on.

As most of those in the following list are seldom if ever used I think they should now be deleted:

- Pil aloes barb.  Pil. ferri carb.
- Pil. aloes soc.  Pil. hydarg. subchlor. co.
- Pil. cambogiae co.  Pil. scillae co.
- Pil. conii co.

Then the following formula might be improved:

_Pil. Aloes et Aesfetida._—I would suggest that syrup would be a more suitable excipient.

_Pil. Aloes et Ferr._—Is the amount of aromatic powder necessary in the preparation? The quantity seems absurd. In ordinary practice, doctors, in prescribing aloes and iron, do not order aromatic powder. If a carminative is necessary a minute quantity of the oloresin of ginger, known as gingerine, might do.

_Pil. Aloes et Myrrha._—Syrup is suitable for this. It might be worth while enquiring if the saffron plays any beneficial part.

_Pil. Aesfetidae Co._—This perhaps is the most suitable method of making this pill.

_Pil. Colocynthis Co._—Water makes the best mass in this case.
Pil. Coloc. et Hyoscyami.—This also might remain as it is.

Pil. Ferri Iodidi.—This is an instance in which the number of pills should be distinctly stated. A note might be added that they should be varnished.

Pil. Hydargyri.—This might be left as it is.

Pil. Ipecac. et Scilla.—Use syrup as an excipient.

Pil. Phosphori.—The present formula is unsatisfactory. The following I find answers well. A phosphatic sucet is made by dissolving phosphorus in a sufficient quantity of bisulphide of carbon, and then incorporating with sucet to make a 10 per cent. basis. Of this basis 10 grs. well beat up with 90 grs. of oil of theobrom, form a good pill mass, which could be divided into 30 or 50 pills, containing respectively 1/300 and 1/500 grs. phosphorus in each. This is practically a modification of Martindale’s formula.

Pil. Plumbi et Opio.—Syrup also for this.

Pil. Rhei Co.—The present excipient is universally condemned. Made with syrup 4 grs. are practically equivalent to 5 grs. of the present mass.

Pil. Saponis Co.—It is questionable if this ought to be retained; certainly the synonym pil. opii should be dropped.

Pil. Scammoni Co.—Is there any advantage in making a solution and evaporating it? Gingerine would answer the same purpose as the tincture of ginger.

Pil. Ferri.—The water is usually unnecessary.

Regarding the adding of new formula if frequency of usage is any criterion as to the pills which should be in the Pharmacopoeia, one might suggest a simple opium pill containing one grain powdered opium in each. Also a podophyllin pill, which seems to be in very general demand.

Another containing calomel, combined with an aperient, might take the place of the present pil. hydrarg. subchlor. co.

---

**Extracts.**

BY WILLIAM SWAN.

**Extract. Aconiti.**—This should be left out. If it was ever greatly in use it has now entirely lost its reputation, and is rarely prescribed. A standardised alcoholic extract of the root would be a distinct advance in the present preparation, but as the extract is not reputedly the best form in which to exhibit the drug, its elimination altogether is more desirable than its modification.

**Extract. Bele Liquid.**—It would be difficult to find a justification for the inclusion of this now entirely disused preparation in a new Pharmacopoeia. Its place has been taken by other and better remedies.

**Extract. Colubrae** should also be left out, and also on the ground of disuse.

**Extract. Belladonnae.**—From any point but that of physical consistency this is a most unsatisfactory extract because of its varying alkaloidal strength and of the difficulty of obtaining any but a very imperfect estimation. The anomaly of a preparation in extensive daily use containing a varying quantity of powerful alkaloid is now generally recognised, and various remedies have been suggested. Most of the recent writers incline to preparation from the root, while all are agreed that standardisation is imperative. The introduction of a new class of preparations similar to the abstracts of the United States Pharmacopoeia has been suggested as a sort of via media, but in a matter so important a straightforward endeavour to solve the difficulty would be more desirable than a compromise. The most satisfactory solution of the position would be to simply standardise the present alcoholic extract, and remove this one entirely.

**Extract. Belladonne Alcoholic.**—The use of a spirituous menstruum all through gives a stronger and more satisfactory preparation.

**Extract. Rhamni Frangula and Rhamni Frangula Fluid.**—Rhamnus bark was re-introduced into the British Pharmacopoeia after a period of neglect. Since then valuable work has been done on the bark; but the introduction at the same time of cascara sagrada and its acknowledged superiority have conducted to its almost entire neglect. Its preparations, therefore, should not be in the Pharmacopoeia.

**Extract. Conii.**—This preparation should, even if its disuse were not a sufficient justification for its elimination, be left out because of its very uncertain strength and of the difficulty in the way of a properly standardised preparation. Its use, however, is so limited that this of itself is sufficient.

**Extract. Cascarra Sagrada Liquid.**—The formula and method of preparation of this extract must be altered; from the outset this has been only too obvious. The process is not only a very tedious but a very imperfect one, and experiment has shown that even after several more boilings than directed, the bark is not entirely exhausted. A much more satisfactory preparation is made by discarding the present method and substituting percolation, or extraction by pressure. Numerous suggestions have been made as to a suitable menstruum, and one which gives an extract of great strength and satisfaction is a mixture of rectified spirit and water, in the proportion of one of spirit and three of water. The formula for the preparation of this extract might read:

Cascarra sagrada (in coarse powder)...... 1 lb.
Rectified spirit......one part
Distilled water......three parts { a sufficiency.

Moisten the bark with the menstruum and allow it to stand for twelve hours. Then transfer to a percolator till exhausted. Reserve the first fourteen ounces and evaporate the remainder by water bath to the consistency of a soft extract. Dissolve this in the reserved portion, make up to sixteen ounces with the menstruum, and filter.

**Extract. Colocynthi.**—The present directions are to evaporate to pilular consistency, but the invariable practice is to use it in the more convenient form of powder, and the pharmacopoeial directions should be modified accordingly.

**Extract. Ergota Liquid.**—A much more satisfactory extract is made by a method in which a minimum of heat or none at all is used, and therefore the present process ought to be replaced by one of percolation or extraction by pressure. The best commercial makes are so prepared, and this in itself is conclusively sufficient authority against the present process.
Ext. Eucalypti.—The chief objection to this is liability to become a solid mass in keeping. The natural cohesiveness of the resinous extract is evidently but little affected by the dessicant added, and magnesia has been suggested as a substitute for sugar of milk.

Ext. Glycyrrhizae, Ext. Glycyrrhizae Liq.—The best commercial extracts are made from the decorticated root, because of the more palatable nature of the product, and the Pharmacopoeia should limit the root accordingly to the decorticated variety.

Ext. Nucis Vomicae.—This preparation has fully sustained the favourable criticism received at its introduction, and has been carefully left alone. The suggestion has, however, been recently revived to add a liquid extract of standard strength for the preparation of the tincture. The suggestion has a much wider import than would appear at first sight. For what would such a liquid extract be but a concentrated tincture? And if you admit the value of a concentrated tincture in the case of nux vomica, it will be difficult to deny the advisability in the case of other and similar drugs. And, again, if you admit the value of concentrated spirituous preparations of such drugs, their concentrated aqueous preparations follow as a matter of course, so that finally you have a pharmacopoeial recognition of concentrated preparations in general. But if the desirability of a liquid extract be granted, of what strength shall it be? A fairly concentrated preparation would not possess any advantage over the present solid extract, except that of being more readily soluble in the menstruum, and would be open to the same objection—the necessity of subjecting it to the action of heat. So that after all we are thrown back on a fluid extract of normal strength, or in other words a standardised tincture prepared direct from the seeds. This was the alternative at the time in the hands of the editors of the present Pharmacopoeia, and as such a preparation is a better one than that at present in use, doubtless it will be substituted in the new British Pharmacopoeia. With the above eliminations and modifications and the following additions the extracts of a new Pharmacopoeia would fairly represent the requirements of the present day:—Extractum bynes, extractum bynes liquidum, extractum convallaris liquidum, extractum suomini liquidum, extractum grindelii liquidum, extractum salicis liquidum, and extractum viburni prunifolii.

5. What is the composition of the metal "D"?
6. Find out the nature of the acid "E." Is it pure?

NOTES.

Manipulation as well as results will be scrutinised. While avoiding hurry economise time, and report results as soon as they are all obtained.

SCHOOL OF PHARMACY.

PHARMACY.
Mr. INCE.
Thursday, March 28.—2 to 5 p.m.

[Four questions only to be attempted.]

1. Describe distillation, and illustrate the application of the process by reference to Spiritus Ammoniaco Aromaticus; Spiritus Armoracide, and Syrupus Pappa-

2. Note the best methods of forming Argentii Nitrae, Potassii Ferriargentane, Pepsinum and explosive compounds into a pliable consistence.

4. Show that one fluid ounce of Tinctura Nucis Vomicae contains one grain of the alkaloids of Nux Vomica.

5. Give reasons for adopting the official formula Extractum Sarsae Liquidum.

6. Write technical Latin for an eye-lotion, a mouthwash, and a spray.

Translate: [Acidum Benzoicum] Sint crystallii albae, splendoris sereci, odoris grati.

MATERIA MEDICA.

Professor Henry G. GREENISH.

Friday, March 29.—2 to 5 p.m.

[Four questions only to be attempted.]

1. Write a short, concise account of Kossoo and of Rhatany root; include diagnostic characters, mention possible substitutes, and indicate how these may be detected by the characters you give.

2. What is "Goa Powder"? Indicate its botanical and geographical source. Describe its formation, collection, and composition. By what means would you endeavour to assay it?

3. What do you understand by rests of physiological and pathological origin? To which class (i.e., physiological or pathological) would you refer the following drugs:—Aloes, canada balsam, peruvian balsam, myrrh, balsam of copaiba, ammoniacum State your reason.

4. Compare quillaja, elm, and slippery elm barks. Point out their morphological nature, diagnostic characters, and chief constituents. Refer them to their botanical and geographical sources.

5. Describe the plant which yields Euphorbium. Indicate the geographical source of the drug. In what part of the plant and in what tissue is it secreted? Describe its collection, appearance, and constituents. Mention impurities it may contain.

6. What is the morphological nature of Jyopodium, juniper berries, ergot, kola wormseed, jalap, barley and calendula?
MAJOR EXAMINATION QUESTIONS.
April 1, 1895.
CHEMISTRY.
Time allowed.—10 a.m. to 1 p.m.
[Six Questions only to be attempted.]
1. Supposing a new element to be discovered, describe what steps would have to be taken in order to determine its atomic weight.
2. Give a full account of the present state of our knowledge concerning the circulation of nitrogen in nature.
3. Discuss the relations which arsenic and antimony exhibit towards the non-metallic and metallic elements respectively, and indicate how these are connected with their position in Mendelejeff's classification.
4. What is the constitution usually assigned to uric acid, and upon what evidence is it based?
5. How are nitro-compounds obtained in the paraffin and benzene series respectively? Mention some of the principal reactions into which these substances enter.
6. Give an account of the chemical relationship of cane-sugar, milk-sugar, grape-sugar, and maltose.
What is glucose? What is glucose alcohol?
7. What is caffeine, how is it obtained in a pure state from natural sources, and how can it be artificially prepared from theobromine?
8. Describe some of the more important reactions of benzaldehyde which are not exhibited by fatty aldehydes.
9. Describe in detail the methods that you have adopted in preparing any two chemical compounds, inorganic or organic. By what means did you ascertain the purity of the substances so prepared?

PHYSICS.
Time allowed—2 to 5 p.m.
[Six questions only to be attempted.]
1. If you look down into a vessel of water, does it appear to be of the same depth as when empty? If not, what is the explanation?
2. Explain the phenomenon of refraction by the undulatory theory of light.
3. What is dialysed? By means of it can any substances usually insoluble in water be obtained in aqueous solution?
4. Describe the construction of the Leyden jar. What takes place during its charge and discharge?
5. Describe what happens when the same electric current is simultaneously passed through vessels containing respectively dilute sulphuric acid, a solution of stannous chloride, a solution of sulphate of copper, and a solution of nitrate of lead.
6. What conditions affect the fusing points of solids and the boiling points of liquids? How are fusing and boiling points determined?
7. If into a kilogramme of water at 0° a current of steam is passed until the quantity of water is 1010 grammes, what will be the temperature of the liquid?
8. If a gas is measured over mercury in an ordinary gas analysis, what observations and corrections are necessary?
9. Describe carefully how you would determine the focal length of a concave lens.

Tuesday, April 2.
BOTANY AND MATERIA MEDICA.
A paper.
Time allowed—10 a.m. to 1 p.m.
1. Describe the structure of the seed of a typical Monocotsylopondous plant. What are the substances which occur as reserve materials in the one you select? How are these utilised by the young plant in the process of germination?
2. What is chlorophyll? Give some account of its manner of occurrence in plants, its properties and functions, and the conditions necessary for the discharge of the latter.
3. Give an account of the way in which the mature cells of the wood are developed from the cambium.
4. What part of the plant Hydrastis Canadensis is used in medicine? How would you recognise the botanical nature of a specimen of the drug as met with in commerce? Give an account of the medicinal constituent or constituents.
5. What are the sources of Pilocarpin? How would you recognise them in the unaltered form and in powder? Describe the active principle as usually prepared. What other alkaloids occur in the same parts of the plants?

PRACTICAL BOTANY AND MATERIA MEDICA.
B Paper.
Time allowed—10 a.m. to 1 p.m.
1. Identify the leaves supplied to you, calling attention to their distinctive microscopical and histological characters. Make such a microscopical preparation as will enable you to point out the latter, and leave it with a lettered explanatory sketch for inspection by the examiners.
2. Make transverse and longitudinal sections of the tissue supplied to you, to display to the best advantage the structure of tracheiferous vessels.
3. Describe the flower provided, and refer it to its Natural Order, giving the reasons for your assignment.

PRACTICAL BOTANY AND MATERIA MEDICA.
A Paper.
Time allowed—2 to 5 p.m.
1. Identify the leaves supplied to you, calling attention to their distinctive microscopical and histological characters. Make such a microscopical preparation as will enable you to point out the latter, and leave it with a lettered explanatory sketch for inspection by the examiners.
2. Make transverse and longitudinal sections of the tissue supplied to you, to display to the best advantage the structure of sieve tubes.
3. Describe the flower provided, and refer it to its Natural Order, giving the reasons for your assignment.

* Part of the candidates received the papers A, A, and the remainder had the papers B, B.
BOTANY AND MATERIA MEDICA.

B Paper.*

Time allowed—2 to 5 p.m.

1. Describe the structure of a mature ovule of a Gymnospermous plant, and point out what part of it, if any, may be described as a prothallus.

2. Give some account of the arrangement of the fibro-vascular tissue in a young seedling of a Dicotyledonous plant, pointing out the differences between stem and root in this respect.

3. Describe the structure of a mature anther and the method of development of the pollen grains in a Phanerogam. What structures in a Fern are homologous with the pollen grains and embosyoa of a Phanerogam?

4. Describe the plant from which opium is prepared. In what part of it is the drug situated? What are the chief alkaloidal products yielded by crude opium? How does the quantity of any of them vary with the age of the plant?

5. Give some account of the chief poisonous Umbelliferous plants that occur in Great Britain, laying stress on those points by which you would identify them while growing.

DONATIONS.

At a meeting of the Library, Museum, School, and House Committee, held on Thursday, the 4th inst., the Librarian and Curator presented the following report of donations to the Society's Library, Museum, and Herbarium:—

To the Library (London).

Smithsonian Institution, Washington:
Smithsonian Report for 1893.

King's College Hospital, London:

Society of Arts, London:
Index to Journal, vols. 31-40.

Dr. R. Kober, Dorpat:
Ueber den Knass.

Mr. J. E. Gerock, Strassburg-Mendorf:
Zur Erinnerung an F. A. Fülliger, 1895.

To the Museum (London).

Mr. L. Wray, jun., Larut, Perak:
Large sample of "Prual" root.
Roots of Dianella enneafoila. Cullawar bark.
"Getah Lunak" and varnished prepared from it.
Malay Hair Oil prepared from coco nut oil and "Pandanu" flowers.

Mr. J. G. Frebble, Bombay:
False Pellitory root, imported from Marseilles.

Sir F. von Mueller, K.C.M.G., Melbourne:
Kino from Eucalyptus calophylla.

Mr. G. F. Scott Elliot, M.A., B.Sc., etc.
"Mutiru" root and "Muavi" and "Ogolo" barks from Uganda.

To the Herbarium (London).

Mr. L. Wray, jun., Larut, Perak:
Specimens of Dianella enneafoila, Garcinia species, Mitragyna species, and the plant yielding "Prual" root.

* Part of the candidates received the papers A, A, and the remainder had the papers B, B.

Mr. J. H. Maiden, Technological Museum, Sydney:
Seeds of Aracaria bidwilli and Fruits of Hibiscus chathamensis.

To the Museum (Edinburgh).

Mrs. Hodgkinson, Treasurer, and Clark:
Specimen of False Chirita (Andrographis paniculata).

ROYAL INSTITUTION.

At the evening meeting on the 29th ult., a lecture was delivered on—

THE STRUCTURE OF THE SUGARS AND THEIR ARTIFICIAL PRODUCTION.

BY PROFESSOR H. E. ARMSTRONG, F.R.S.

At the outset, the lecturer alluded to the way in which organic chemistry had of late been neglected at the Royal Institution, and commented upon the methods followed in this branch of science. Incidentally it was said, that although the mathematical training received at school was of great assistance subsequently in scientific work, yet the chemistry there learnt was no use as a basis for future investigation. Professor Armstrong's remarks were mostly confined to the researches in the sugar group conducted by Professor Emil Fischer and his assistants, which were characterised as being infinitely more important than the majority of work done in other branches of chemistry. Some statistics were first given of the production of sugar, and its relative consumption in Great Britain and other countries, allusion being made to the way in which beet has now replaced cane sugar, only a small amount of that used at the present time coming from the latter source.

The structure of the most important members of the sugar group, especially glucose, fructose, maltose, and lactose, was described minutely, and the various properties illustrated by the aid of experiments. The latter for the most part illustrated their relative reducing effect upon alkaline copper sulphate solution. The optical properties of the sugars were fully described, and in discussing the symmetrical and asymmetrical carbonates, Pasteur's work on the various modifications of tartaric acid was noticed. It was demonstrated that the most important reagent for the study of the sugars is phenyl hydrasine C,H,NO,NH. As a typical experiment, solution of glucose was mixed with phenyl hydrasine acetate solution. As a first stage of the reaction the crystalline compound phenyl hydrasone is formed, which contains the hydrasone residue; on heating, more phenyl hydrasone enters into the reaction, and the compound phenyl osazone is formed. These two compounds, which are typical of the class, are both crystalline substances of definite melting point, and from any hydrasone or osazone the sugar used to form it can be regenerated.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting was held on Thursday, March 28, Mr. H.T. Durant, Vice-President, in the chair. The business commenced with a series of dispensing notes, and examples of incompatible or remarkable prescriptions
communicated by Messrs. Tickle, Read, Davis, Hill, Brown, Stoddart, Jealons, Dyson, and Durrant, which were discussed and commented on.

Mr. H. Brown then took the chair, and a report on inorganic chemistry was read by Mr. A. T. Hill. The report gave rise to a discussion in which the Chairman, Messrs. Durrant, Read, Tickle, and the Secretary took part. It was unanimously resolved that the Executive Committee should be instructed to make arrangements, as in previous years, for botanical excursions on Saturday afternoons.

The meeting then adjourned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

There was an average attendance at the meeting of this Association on the 28th ult., when the evening was devoted to short papers and discussions. The President, Mr. R. H. Jones, occupied the chair, and, after the reading of the minutes, called on Mr. W. A. Jones to read his paper, entitled:—

A FEW NOTES ON THE COMING REVISION OF THE BRITISH PHARMACOPOIA, FROM A DISPENSER'S POINT OF VIEW.

BY W. A. JONES.

The author commented upon the inferior style in which the Pharmacopœia is at present bound and the bad quality of the paper, and then went on to advocate the introduction of several new preparations and classes of remedies. He was of opinion that urethral bongies, 20 grain size, should be introduced, with such combinations as belladonna, carbonate of bismuth, cocaine, tannin, and lead acetate. The fluid extracts should be considerably increased by the addition of preparations of belladonna, calumba, digitals, hyoscyamus, nux vomica, and rhubarb; and he was in favour of the process given in the U.S.P. for those preparations, which gave very satisfactory results. As an instance of the unsatisfactory processes for fluid extracts at present official, he cited taraxacum, in which at the commencement a menstruum of proof spirit was used, but finally exhaustion was completed with water. On mixing these two liquids a deposit of mucilaginous matter resulted which was difficult to filter off. On the other hand, in the U.S.P. the same menstruum was used throughout.

With regard to the alcohol, a modification of the plan used in the French Codex was recommended, by which any strength of spirit could be ordered by affixing the number of degrees in Syke's hydrometer it should correspond to, as there were many cases in which it was not advisable to be restricted to the use of proof or rectified spirit extract. Ext. cinchone liquid, should have characters and tests appended, and a specific gravity should be given. Concentrated infusions and decoctions should be recognised officially, in addition to those at present included. They were extensively used, and were sometimes specially ordered by the profession, and it was advisable that some standard should be fixed for them. An injection of morphine and strychnine should be introduced, and as camphor water had been shown to be of little or no use as a preservative of this class of preparations, carbolic acid was perhaps preferable. The injection of argentin was variable in strength, by reason of the directions for preparing argentin itself being indefinite. It was preferable to use pure morphine for the injection instead of its salt, and attention was drawn to the fact that the present strength was really practically identical with that of the B.P. of 1867, owing to the difference in the two morphine formulae. If morphine alkaloid were introduced a test providing for loss of weight and drying was necessary. Turning to the percentage solutions, Mr. Jones advocated the abolition of the grain measure, and instead of having the strength of this class of preparations 1 grain in 100 fluid grains, would either revert to the old plan of 4 grains to the fluid ounce, or 1 grain in 100 minims. The directions for liq. strychnin. hydrochlor. should be altered so as to ensure a definite finished volume.

A solution of nitrite of ethyl should be introduced, and additions to the oleates made by those of bismuth and copper. The official list of suppositories should be increased and formolin introduced for Easton's Syrup, compound syrup of the hypophosphites, and Parrish's Syrup. The want of consistency in the directions for ointment making was noticed. Thus, we are told to "rub till perfectly smooth and free from grittiness" in the case of sulphurated potash ointment, but only to "mix thoroughly" in ammoniated mercury ointment, although the latter is equally difficult to turn out satisfactorily.

A paper was then read on—

THE INTRODUCTION OF THE METRIC SYSTEM INTO THE BRITISH PHARMACOPOIA.

BY W. ANDERSON.

In this the author advocated the adoption of this system of weights and measures only in the next Pharmacopœia. He did not think the two standards could work side by side, as confusion would only result. He was of opinion that it was the most scientific and nearest approach to a perfect system yet put forward, and that its use would lead to a large increase in our export trade. He was glad to see it had many influential supporters, and trusted the new B.P. would see it adopted solely.

In the discussion that followed, Mr. Dyson was of opinion that the B.P. should be cut down, and a wholesale abolition of obsolete preparations carried out. With regard to Mr. Jones' remark on the official ointments, he thought the pharmacist should need no particular directions in such instances as those quoted. He did not think the metric system well adapted for dispensing purposes in this country.

Mr. Taylor was in favour of the deletion of most of the confections, and alluded to the growing absurdity of physicians prescribing nostrums, which he attributed to their inability to write a prescription properly.

Mr. Guyer hoped that before Easton's Syrup was made official, a satisfactory formula would be discovered, as it was still a desideratum.

Mr. Meluish put in a word for the retention of the
soap basis for some suppositories, and denounced the proposal to introduce therapeutics into the national medicine book.

The President, in complimenting Mr. Jones upon his paper, pointed out a few misapprehensions which previous speakers had been under as to the introduction of concentrated infusions and decoctions. Mr. Jones merely suggested their recognition, not that they should supplant those in use now. He thought that a series of ointments prepared by double decomposition should be introduced. Solution of ethyl nitrate should not be recognised until its therapeutic advantages were definitely established. As to ointment bases, good lard was hard to beat for general purposes, and he hoped that lanolin would meet with further recognition. Although in favour of the introduction of the metric system into the Pharmacopoeia, he did not advocate its appearance in the Minor schedule at present.

Messrs. Hill, Morley, Roberts, and others joined in the discussion, and Messrs. Jones and Anderson having briefly replied to various points raised, the rest of the evening was devoted to dispensing queries. In the first of these Mr. E. W. Hill mentioned a prescription he had dispensed for sodium nitrite in pills. With ordinary excoptiens red fumes were evolved and the pills attained abnormal sizes, but by using kaolin ointment the difficulty was overcome. Mr. W. Anderson then mentioned that when preparing compound syrup of hypophosphites recently it was noticed that H₂S gas was evolved. It was the general opinion that it was due to the presence of ultramarine in the sugar used, which, on being decomposed by the acids, gave rise to the H₂S gas. Mr. C. Morley opened a discussion as to the best course to adopt when cocaine hydrochlorate was ordered in an ointment or suppository. It will be remembered that this point was referred to recently in the "Notes and Queries" column of the Pharmaceutical Journal (ante, p. 539). Messrs. Taylor, Dyson, Bainbridge, Roberts, and the President assisted to elucidate this with various suggestions. It was generally agreed that if it were permissible to use the alkaloid in an ointment, the best plan was to neutralise it with oleic acid and mix with the basis in the ordinary way. If, however, the use of the salt was compulsory, as it is only slightly soluble in fats, the best plan seems to be to rub it down to a very fine powder, then add a drop or two of water and mix with the basis gradually.

Mr. E. H. Hill had had the following mixture to dispense:—

Bromofom
Water to

He had found the best plan was to emulsify it with tincture of quillias, four draehms being sufficient for the above quantity of bromoform. Mr. Bainbridge stated that equal parts of bromoform and tincture of senega gave a very presentable mixture.

In the last note Mr. C. Morley recommended the use of graphite in the form of ordinary plumago as a coating for the pharmacopoeial Bland's pills. He had got good results by its use, as the pills did not readily oxidise or become "pitted."

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

A meeting was held at the Royal Institution on Thursday, March 28, Mr. J. Smith, President, in the chair.

The President remarked that in the latest edition of the U.S.P. the use of phosphate of calcium is ordered in the preparation of some of the aromatic waters, and knowing that the method has been recommended in this country, thought it worth mentioning that while a water of fine aroma can be obtained, the process has a serious disadvantage in the partial solubility of the calcium phosphate. An aromatic water so prepared is incompatible with ammonium carbonate or other substances which react with a phosphate or a calcium salt.

Mr. A. C. Abraham said the solubility of phosphate of calcium had been mentioned before, and the use of it objected to on that account. Personally, he did not see any necessity for using any powder whatever.

Mr. C. J. S. Thompson also referred to the subject of aromatic waters, and thought that in the next Pharmacopoeia it would be advisable to have a process by which the waters prepared with essential oils could be conveniently prepared by the average working pharmacist without distillation.

Mr. Edward Davies, gave an abstract of an address he had given before the Liverpool science students, the subject selected for him having been the "Centenary of Lavoisier."

The following paper was then read:

THE PHARMACOPEIA REVISION.

BY C. SYMES, PH.D.

When it was decided that the London, Edinburgh, and Dublin pharmacopoeias should be consolidated into a British Pharmacopoeia, considerable interest was evinced on the matter. The same appears to be the case now that it is proposed to make that Pharmacopoeia what it should have been, viz., an imperial one embracing the pharmacy of our colonies. Suddenly it seems to have become the duty of certain persons to make themselves acquainted with, to criticise, and to denounce the work which we have hitherto regarded with entirely different feelings. The medical critics start with the assumption that the Pharmacopoeia exists chiefly, if not exclusively, for the benefit of their profession, and, judged from that point of view, they pronounce it a failure because it contains many drugs and preparations with which the said critics are not familiar, and because it does not contain those little formulae for combinations of drugs put up in a ready-made fashion nowadays. Under this first head they proceed to apply the pruning knife most vigorously, and under the second they suggest that this book should "contain tablets" and some therapeutics.

The pharmaceutical critics regard the work as being of equal importance to their own calling, and from their positions as dispensers of medicine they are able to judge of the wants of a very large number of medical men, as well as of their own. They are thus enabled to bring forward views to bear on the subject,
and to exercise what appears to me more just criticism. It is the more general knowledge required, as well as the important interests to be conserved, which, to my mind, justifies the pharmacist in claiming a full representation on the Pharmacopoeia committee. I have said that the additional interest attached to the present revision is due to the proposal to make it embrace the pharmacopoeial interests of our colonies. This, however, is really not new. In the prefaze of the B.P., 1867, it is stated that the work is produced; in compliance with the Act of Parliament, 25 and 26 Victoria, and that it is intended to afford to the members of the medical profession and those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide. Now, if the British Empire means anything, it means not only Great Britain and Ireland, but also our colonies. What is meant, then, is that this object should be carried out more completely than has hitherto been done, by adding such remedies as are in use and have a well-established reputation in colonies although not in general use in this country. This is the intended and proper scope of the work, its nature being defined in the Med. Act of 1858, where it is enacted that the "General Council shall cause to be published under their direction a book containing a list of medicines and compounds and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed, and containing such other matters and things relating thereto as the General Council shall think fit." Clearly, then, it is the province of the medical faculty to decide what the book shall contain, but in arriving at the conclusion as regards the drugs and preparations, considerable help could be afforded by the pharmacist. The analysis of 10,000 prescriptions published by Mr. Martindale ought to be of service in this way, and would certainly have been largely so had it covered a wider area. If it is desired on the part of the medical profession to have "other matters" relating to the drugs and preparations embodied in the work, it is quite competent for the General Council to do such, and although we might not approve of extending the matters to therapeutics, it would not be our duty to offer any protest.

Broadly, I would say more mischief is likely to arise from curtailing the materia medica than from retaining or adding something which may appear to be superfluous. Take, for example, "menthol plaster." I could never understand why that was included in the work, as in my experience the demand for it is exceedingly small; but if in some localities it is occasionally used, a formula for it is desirable, and I am perfectly content that it should remain. The cataplasmata are not often prepared by the pharmacist, it is true, but they are occasionally so, and they are at least good formulae which the medical man can recommend to his patients. The enemata are frequently prepared though not so often dispensed in a pharmacy, and yet the formulae are very useful to the medical practitioner. Why should either be removed? We are told that it is superfluous to have several preparations such as tincture, infusion, and extract of any one drug; but this statement cannot be sustained by reasonable argument, it is merely theory. It is stated that the standards of quality are too low, that the tests for purity are not sufficiently exacting, and that there is a want of uniformity in the strength of the various preparations. Persons who work in this way seem to ignore the existence of the Food and Drugs Act, and the fact that scientific accuracy in pharmacology is decidedly in advance of that in therapeutics, and they are willing to sacrifice practical utility to appearances.

In my opinion the Pharmacopoeia aims at being thoroughly practical, rather than theoretical. When published it was quite up to date and as much ahead of the times as any similar work of the period. It, like all other books, contained a few errors, and no doubt note has already been made of these in preparing for the new edition. For example, we shall have goa powder or araroba mentioned as the source of chrysarobin (commonly called chrysophanic acid), instead of being mixed up with it in a way calculated to mislead. The formula for either the solid or liquid extract of cascara will doubtless be modified, as both cannot be correct.

The hypodermic injections of ergotin and morphine would be better if less concentrated—there would be greater accuracy in their administration and less local irritation would be caused by their use. The latter has been made more concentrated merely to comply with decimal proportions, making it far more difficult for the medical practitioner to administer accurately 1/6 or 1/4 grain. Further, as the strength of the other two preparations of this kind bear no similar decimal relation, what avail it in this case? The two essences of aniseed and peppermint are also much too concentrated; 1 in 8 or 1 in 10 would make a much better essence for dispensing purposes, and would correspond with the articles for many years sold to the public and to which they have become accustomed. Essence or strong tincture of ginger has on the other hand been reduced in strength from the popular article, 1 lb. to the pint, and why? simply to make the proportion 1 in 10; but as 10 cwt. of spirit do not weigh 10 cwt. the object is frustrated. It may suit the purpose of the student who wants to cram to have more decimal strengths irrespective of convenience of dose and manufacture, but is it worth doing? Much as I admire the decimal system for purely scientific purposes I do not think it is practical in a pharmacopoeia in the present days. I think the doses should be retained, most certainly they are useful to prescriber and dispenser. Whether any other matter of a similar nature should be added to make the book more popular with the medical profession must rest with the Medical Council.

The President, in inviting discussion upon the subject of Dr. Syme's remarks, thought that, in the opinion of medical men, pharmacists had been too ready to offer suggestions and to criticise when it was known that a new edition of the Pharmacopoeia was in contemplation. Pharmacists make no claim to decide
what new preparations shall be added or obsolete ones removed, but they do claim to have a voice in the methods and processes by which preparations are made. The Pharmacopoeia as it stands is largely the work of pharmacists, and the recommendations contained in the annual reports of the editor, Dr. Attfield, from which the bulk of the information which will guide the pharmacopoeia committee will be derived, have to a very large extent been culled from the published reports of meetings of pharmacists. It is not unreasonable, therefore, that pharmacists should claim to be openly recognised where they actually supply so large a portion of available information.

Messrs. A. C. Abraham, Cowley, Hornblower, C. J. & Thompson, and others continued the discussion on the general question of pharmacopoeia revision, and Dr. Symes replied to questions put to him in the discussion.

---

**Scottish Transactions.**

**EDINBURGH CHEMISTS, ASSISTANTS, AND APPRENTICES’ ASSOCIATION.**

At the meeting held on Friday, March 29, the following papers were read:—

**BELLADONNA PLASTER.**

**BY PETER BOA.**

This plaster is of considerable importance. Of the official plasters it is one of those most frequently used. The formula for it, which is now in the Pharmacopoeia, gives rise to two objections, viz., that the plaster is too soft and runs, and that it is wanting in adhesiveness. The softness is caused by the large proportion of extract which it contains. Considering the potency of alcoholic extract of belladonna, it is worth while inquiring if it be really necessary that it should contain so much. The medicinal effect of the plaster is presumably due to a certain amount of absorption of the alkaloidal contents of belladonna, and looking at the matter in this light we find that its "possibilities" are startling. If we take, for illustration, a plaster 7 × 6 inches—the size of a 2 oz. paper—and allow the usual quantity of 20 grains to a square inch, 840 grains are required; of this one-fifth, 168 grains, is alcoholic extract, of which the maximum dose is 4 grain.

Assuming that one-fourth of the spread plaster is in contact with the skin of the body, it is apparent that one hundred and sixty-eight maximum doses are presented for absorption.

Plasters are ordered in various sizes, some are smaller than the one I have taken for illustration, but many are larger. It appears to me therefore that the quantity of extract in the plaster is extravagant, I might almost say reckless. The ointment contains only 1 in 10. I would suggest that 1 in 10 is quite a sufficient strength for the plaster. An increase in adhesiveness may be conferred by altering the formula to contain more resin, e.g.:

<table>
<thead>
<tr>
<th>Resin</th>
<th>Cudr soap</th>
<th>Lead plaster</th>
<th>Alcoholic extract of belladonna</th>
</tr>
</thead>
<tbody>
<tr>
<td>5 parts</td>
<td>2 &quot;</td>
<td>11 &quot;</td>
<td>2 &quot;</td>
</tr>
</tbody>
</table>

**SUGGESTED B.P. EMULSIONS.**

**BY CLAUDE F. HENRY.**

The present-day demand for elegant pharmacy and agreeable medicine warrants, at least, the consideration of the claim of emulsions to a place in the next pharmacopoeia. The object of the present note is to suggest a few formulae for the emulsions most frequently in request. Speaking generally, a creamy emulsion is to be preferred to a paste, and as to flavour, those I have suggested are what are personally agreeable to myself; but tastes differ, and these can be changed. Gum acacia has been adopted as the emulsifying agent, because of its being ready for use sooner than tragacanth, ghatti, Irish moss, etc., and requiring less preparation.

The following is the suggested formula for emulsion of morrhue:

**Take of:**

| Gum acacia | 1 ounce |
| Cod liver oil | 4 ounces |
| Elixir of saccharin | 40 minims |
| Oil of castor | 2 minims |
| Hypophosphite of soda | 16 grains |
| Hypophosphite of lime | 16 grains |
| Distilled water, q.s. to make | 8 fluid ounces |

Make a mucilage by dissolving the gum acacia in two ounces of the water. To this gradually add two ounces of cod-liver oil, stirring constantly until a thick emulsion is formed, then add two ounces more water, in which the hypophosphites have previously been dissolved, and stir in as before the remainder of the oil. Add next the saccharin elixir and the oil of castor, mix thoroughly, and make up to eight fluid ounces with distilled water. A 50 per cent. white creamy emulsion is thus produced. 75 per cent. of oil can easily be incorporated, but such an emulsion requires more flavouring, and is not so well tolerated by the stomach.

In preparing the emulsion the whole gum, which can be broken up in a mortar to facilitate solution, should be used in preference to the powder, and the mucilage should be prepared fresh when required, the tendency to acidity being thus prevented. The formula would necessitate the inclusion of elixir of saccharin and oil of castor in the B.P. The former is a very useful preparation, and that suggested by the B.P.C. unofficial formula committee should be chosen. The emuldo olei morrhue of the B.P.C. is not so good as the above. Its sickly colour is an objection, and eggs are not well suited for pharmacoeutical manipulation even when they can be obtained fresh. A satisfactory castor oil emulsion is also, I think, a B.P. want. The mistura olei riciui of the present B.P. is, I think, objectionable, because of its being prepared with liquor potasse, and because of the quantity directed to be used, the maximum dose, 60 drops, being required for each six drachms of oil;
Correspondence.

The Major Examination.

Sir,—Having been asked for my views respecting the division of the Major examination into two or more parts, I have ascertained the opinions both of present students in college and past pupils who are in business on their own account, and from the replies received, I am confident that such a change would not only be welcomed by students generally, but would greatly benefit our Society by increasing the number of Major candidates, and as a result considerably augment the number of members of the Society. On going through the list of Westminster men in business as chemists and druggists (numbering over 700), I regret to find that only about 20 per cent. of these are connected with the Pharmaceutical Society as associates, while over 90 per cent. of those who have passed the Major examination have become members. This fact is alone, I think, sufficient proof of the advisability of, in some way or other, encouraging young men to continue their studies for the Major. On an average not more than 6 per cent. of our men can be induced to pursue their studies after passing the Minor. To thoroughly prepare for the Minor under the present regulations necessitates a great strain both on the mental powers and financial resources of the students. I feel persuaded that if the Major examination were divided into two portions only, practical and theoretical (though I would suggest three divisions, practical chemistry, chemistry and physics, and materia medica and botany), that quite 30 per cent. of the successful candidates could be induced to continue their studies in the laboratory for another three months in order that they might pass the first portion of the examination, with a view of at some future time taking up the theoretical work, which portion could be passed by any student of ordinary ability without leaving business.

South Croydon.

G. S. V. WILLS.

Sir,—I have hoped that the suggestion of one of your correspondents, that candidates for the Minor and Major might be permitted to present themselves for examination in one or more subjects at a time, would be sufficiently important to deserve editorial comment. I suppose it will be generally admitted that the pharmaceutical body would be strengthened and the tone of the business raised if there were a larger proportion of Major men. A comparison between the percentage of Major men and of Minor men who remain outside the Society would be interesting. If my opinion is correct that a much larger percentage of Major men subscribe to the Society, it would be a strong argument in favour of the suggestion. It has been pointed out, and is perfectly true, that many having passed the qualifying examination and gone into business would most gladly continue their studies if a prospect of passing the higher examination, without having to leave business, was offered itself. Every inducement and facility should be held out to pharmacy students to aim for the Major, both in the interests of higher education and of organisation. If there are good reasons why the suggestions should not be adopted, many would be glad to have them stated. If there are no such reasons it is to be hoped the matter will be taken up earnestly by the Council.

SIR.  I—find that my manuscript notes furnished to you last week contained a hiatus which I should like to fill up. On page 555, column 2, lines 19 and 20 from top, at the end of the sentence—"as I will endeavour to show,"
should follow.—Ext. anthemidis is directed to be made by boiling one pound of the flowers in a gallon of water until the volume of liquid is reduced to one-half, etc., and I mentioned that chamomile flowers contained more volatile aromatic principles than any of the other substances used in making infusions. Ext. cassarea sag. lig. is also directed to be prepared by boiling the bark in successive quantities of water. Syr. papaveris is also directed to be made by first infusing the capsules in four pints of boiling water, then percolating an additional quantity of boiling water until two gallons are obtained, or the mass is exhausted, afterwards evaporating down to three pints. In the preparation of vin. IOpoeae, we know how long and continuous heat must be employed to obtain a dry extract, which I have never yet been able to obtain.

Glasgow.

R. BRODIE.

THE REMUNERATION OF DISPENSERS.

Sir,—To those of our craft who are doomed by circumstances to be employed instead of employing, your article of last week is especially gratifying. It is necessary at times to draw the attention of both the members of our calling and of the public to the question of remuneration. Owning largely to the peculiar position we occupy between the trading and the professional class, more than those of any other department of workers, our claims are unconsidered; and I am convinced we shall never be more respected by the public until we have demanded that respect. While the ungenerous treatment of retail chemists is driving reluctant men to the parrot-like employment of the drug stores, those public gentlemen who constitute boards of guardians have no adequate knowledge of—no proper means of estimating—the value of a dispenser. Let me bespeak a little more consideration for the county dispenser. Outside London, where enlightenment most readily dawns, the dispenser is often treated, as far as remuneration goes, as a mere labourer. Here in Manchester, for example, a city which boasts its ready appreciation of merit, the assistant dispenser receives in a never-increasing salary of £36—a fortnight ago the Board of Guardians required a qualified dispenser for £76! Three months ago, the West Riding Asylum of Wakefield offered the magnificent sum of £104 for a pharmaceutical chemist! Do our “boards” consider these amounts are satisfactory to men of education and taste?

Manchester.

A. P. S.

Sir,—As a poor law dispenser I sincerely thank you for your leader of March 9th. I trust the Local Government Board may soon see fit to raise our maximum salary, as at present it is not proportionate to our work and responsibility. The great improvements made of late years in the administration of the poor law, more especially in the relief of the sick, also make it most desirable that we should be men of good education and thorough capability. I trust all pharmacists and medical men who are guardians will support your suggestion.

GEORGE WALMSLEY.

St. Pancras Workhouse Dispensary, N.W.

THE SHAPES OF ATOMS.

Sir,—I see by your issue of this week that Lieut.-Col. Sedgwick in the Chemical News claims to have anticipated argon from his theory, published in 1890, that valency depends on the atoms having flattened sides. Now, why not allow my claim, though I am only a chemist and druggist? I enclose you a printed sheet entitled a “Theory of Things,” which I published as far back as 1881. In this occurs the following: “The chemical atoms are masses beyond the general power of the other to subdivide; monads are semi-spheres, each monad atom has therefore one flat side whereby it can adhere; diads have two flat sides, with all their other surface convex; triads have three flat sides, etc. Three theories there are, which can all reasonably enough explain how the atoms by gravity took these shapes; but it is enough to say here that the atoms must have these shapes or chemical action could not act as it does.” The first of the above three theories referred to is that “on the formation of the element atoms the cohesive force in their substance would first constitute them spheres thoroughly rounded, but before they had time to harden, so to speak, or became permanently fixed in that shape, mutual contact with each other would flatten certain portions of their surfaces; of course, the ether fluid in which they are bathed preventing their contact from becoming fixed connection.” (Vide Pharm. Journ., February 23, 1885, Epitome, p. 61.) Hence it is more than probable that there will be atoms without valency, and they are most likely to be found in the higher reaches of the atmosphere. In fact, I might with certainty predict that the very topmost layer of the atmosphere is composed of an element lighter than hydrogen and without valency.

Glasgow.

J. J. BROWN.

DETERMINATION OF GLUCOSE.

Sir,—I observe from the report on page 582, that at the meeting of the Chemical Society held on the 31st ult., Professor Brauner described a modification of Pavy’s method of determining glucose by its reducing action on ammoniacal Fehling’s solution. The modification consists in covering the copper solution with a layer of vaselin or paraffin oil. I described this plan some months ago, my method of operating being fully described in the Lancet for July 28, 1894, page 213; the Pharmaceutical Journal for the same date, page 90; and the Analyst for August, 1894, page 161. The prior publication of the suggestion has evidently been overlooked by Professor Brauner.

Sheffield.

ALFRED H. ALLEN.

Answers to Correspondents.

R. Cleare.—You will find Jevons’ “Elementary Lessons in Logic” (Macmillan) very suitable for the purpose you mention.

“S. T.”—You are not likely to see a new edition of the British Pharmacopoeia for some years yet, since even the preliminary arrangements for revision are not yet made.

“Analyst.”—Legg’s “Guide to the Examination of the Urine” (H. K. Lewis, London, 3s. 6d.) is one of the most recent and useful works on the subject. More advanced information will be found in Halliburton’s “Chemical Physiology and Pathology” (Longmans and Co., London, 25s.).

“Chemist.”—Are you certain of the facts in your statement, and if not, have you been some other disturbing influence? We shall be pleased to inquire into the matter if you will write along, giving full particulars of the case described, which we assume was an actual one, and not merely hypothetical.

Corrections.—In Mr. Brodie’s paper, published last week, for “Distilled water, to 8 fl. oz.,” read “Distilled water, 8 fl. oz.,” in the formula for mist. goutens on page 584. In the same column, also, lines 10 and 17, for “some waters think,” read “in some cases this.” These errors were due to imperfections in the manuscript.

Notes.

President of the Chemical Society. — Dr. Augustus Vernon Harcourt, F.R.S., the newly elected President of the Chemical Society, is a son of the noted Admiral, and a son-in-law of the late Lord Aberdare, besides being a distant relative of the Leader of the House of Commons. He is Lees Reader in Chemistry at Oxford University, and in conjunction with Mr. Madan, of Christ Church, produced the well-known text-book in practical chemistry.

Bacteriological Wonders. — The readiness with which the daily newspapers nowadays publish the grossest absurdities regarding alleged bacteriological discoveries is very marked. One of the latest wonders of this kind is the claim made by a Dr. Wheeler, of Chicago, to have discovered what he terms "the microbe of death," which can be destroyed like other microbes. It is said to resemble the microbe of consumption, and with its destruction nothing short of actual violence can, says the discoverer, put an end to anyone's term of existence. Another announcement is that a young Vienna physician, Dr. Marmorek, at present with Dr. Pasteur, in Paris, has discovered the bacillus the presence of which is declared to be the active cause of blood-poisoning and of inflamed wounds. He has named the bacillus Streptococcus pyogenes. Now, seeing that this organism, which, by the way, cannot be both a bacillus and a streptococcus, was first identified years ago and named by Rosenbach, and that besides being very common in smallpox and numerous fevers, it occurs in abscesses, gangrene, etc., Dr. Marmorek's discovery appears neither so novel nor important as might be imagined.

Bakerian Lecture. — The Royal Society's Bakerian lecture which will be delivered on Thursday, May 9, is to be 'On the Laws of Connexion between the Conditions of a Chemical Change and its Amount.' It is to be based upon a research by Mr. A. Vernon Harcourt and Mr. William Esson.

Pharmaceutical Examinations. — The proportion of failures in the examination for registration as pharmacists in Massachusetts is vastly in excess of what is customary in this country, if the figures quoted in a Boston paper may be taken as accurate; for, according to this, the State Board of Registration in Pharmacy, at its session held March 5, 6 and 7, examined forty-three applicants for registration and granted certificates to five only.

Free Trade in Poisons. — In a recent number of the Globe (see p. 120) the opinion is expressed that all poisons should be scheduled, instead of the limited number so treated at present, but our contemporary fears that such a beneficial reform would be "howled at by the trade as undue interference with commercial freedom." If "the trade" is to be interpreted "chemists and druggists" there is little reason to fear that they would object to so salutary a proceeding, though very decided objections might be anticipated from other traders.

The Trade in Ganja. — Another instance of the difficulty of coping with the abuse of narcotics in the East by means of Government regulations is supplied by the fact that the attempt to suppress the importation of ganja into Burma is admitted by the Hemp Drugs Commission to be a failure. It is alleged that, despite the vigilance of the Excise officers, an enormous illicit trade has been carried on for some time past.

Is Oxygen a Mixture? — At the weekly meeting of the Royal Society, held on Thursday, March 21, Professor Rayley (on behalf of Dr. Bayley) made a preliminary announcement of some very remarkable experiments on oxygen. Two globes, connected by a glass tube and containing electrodes, were filled with oxygen. The apparatus, which is exactly like a dumb-bell, was filled with pure oxygen, and electric sparks were passed for some time from end to end of the tube. Whilst the sparks were still passing the bulbs were separated by sealing off with the blowpipe the connecting tube between the globes. The gas in each globe was then examined, and it was found that the densities of the two gases were 15.88 and 16.01, the mean of which approximates to the actual density of oxygen. It may be that in this experiment oxygen has been split up into two gases of different densities, and the results are very suggestive of the meta-elements or different degrees of condensation of protyle, as mentioned by Crookes. The confirmation or explanation of these results will be eagerly awaited by all chemists.

Parish Council Elections. — Mr. Richard Clark (Messrs. Raines, Clark and Co.) heads the poll for Stephen's Ward, Edinburgh, and Mr. David McLaren, 42, South Clerk Street, heads the poll for St. Leonard's Ward. There were four candidates for two seats in the former ward, and three candidates for two seats in the latter.
Miscellaneous News.

SELLING ACETIC ACID ABOVE STRENGTH.—At Clerkenwell, on March 29, Alfred Honman, chemist, Upper Street, Islington, was summoned by the Islington Vestry for selling diluted acetic acid containing 11.7 per cent. of acid, which was 2.74 times the correct amount, and therefore too strong, according to the Pharmacopoeia. Dr. Harris, medical officer of health, said that it was essential that drugs should be of the exact strength laid down in the Pharmacopoeia. Mr. Horace Smith said he felt in a difficulty in the matter. The intention of the Foods and Drugs Act, in his opinion, was to prevent fraud, such as the dilution of milk or beer, but here the defendant was defrauding himself by selling something stronger than it need be. Dr. Harris said that if drugs were sold over-strong they might do harm to a person, or even cause death. Mr. Smith said that would lead to a charge of manslaughter. He hardly thought, with regard to the Foods and Drugs Act, that the Legislature had in mind cases of this kind. There seemed some need for a special provision. The defendant did not appear to have committed an offence under the Act. He would take time to consider the point, and give judgment which might lead to the point being decided by a higher court.

PHARMACEUTICAL FOOTBALL MATCH.—South London School of Pharmacy v. Westminster College. The return match between these clubs was played at Tooting on Saturday, March 30, when the South London team succeeded in reversing the result of the previous match, winning by one goal to nil. "Muter's" were not fully represented owing to three or four of their original eleven having left town for the Easter vacation. A very fast game, however, ensued, in which the South Londoners had the best of the exchanges, winning as above stated. Plumstead (who scored the goal), Dawson, Cooper, and Chambers played a grand forward game for the winners, whilst Smith on the outside right and the defence were the pick of the losers.

A FAMILY COMPANY AT TORQUAY.—At a special sitting of the Exeter Bankruptcy Court on March 28, an application was made to his Honour Judge Edge, re the Bayliss Drug Company, Limited, Torquay. It was stated that Mr. Bayliss was the manager of the Company, the only other members of which were connected with his family. There was a petition to wind up the Company by Mr. Bayliss as a contributory, and there was a petition by the creditors against Bayliss personally as being practically the Company. The Sheriff had sold, and this had constituted the act of bankruptcy. A point urged on behalf of the creditors was that in the event of the Company being wound up, the execution creditor would get the benefit; but if the receiving order was made, the Official Receiver would be entitled to the proceeds of the execution for the benefit of the creditors generally. Mr. W. Dale Bayliss was examined, and said he was now residing at Heavitree with his mother and father-in-law. Prior to December, 1893, he resided at Stoke-on-Trent, where he carried on the business of a drug merchant. It was now conducted by his brother, to whom he sold it for £800. In December, 1893, not being a duly qualified chemist, he formed a Company for the purpose of carrying on the business of a chemist and druggist. He purchased a business from Mr. Ness, of Lower Union-street. The subscribers to the Company were himself, his wife, Walter Bayliss, his brother, his mother, his mother-in-law, his father-in-law, and Charles Bayliss, his brother. Each said £1. The nominal capital consisted of 2,000 shares of £1 each. None were offered to the public. He took 999. His Honour said that in his opinion, the registration of the Company was a mere sham. So far as Mr. Bayliss and his creditors were concerned, they stood in the direct relationship of debtor and creditor. It seemed to his Honour that there was an ancient act of bankruptcy against Mr. Bayliss to adjudicate him a bankrupt. He did not want to make an order for the winding up of the Company, and if he did he would be admitting that the Company was a properly registered one, which he did not believe. He therefore adjourned the case until the next Court. The adjourned order would be continued, and the winding-up petition would stand over.

FREE TRADE IN POISONS.—The Globe remarks that "it is supposed that the law presents great difficulties to people who meditate the poisoning of themselves or other folk. The sale of certain deadly drugs is indexed roughly with a list of stately names by a paternal Legislature; no intending murderer would attempt to obtain them at the risk of almost ineluctable detection. Nor is there any need; for drugs can easily be obtained which bring about death with equal certainty. You have merely to drop in at a chemist's shop, and ask for rat poison. Any man did the other day when his thoughts lightly turned towards suicide. Two penn'orth sufficed; a pound of strychnine or of any other scheduled drug could not have wound up his earthly career more effectually. If, however, there be demand for such a vulgar cure for all the ills of life as rat poison, example may be taken from another citizen of Derby, who simultaneously operated on himself fatally with laudanum. Then there is a third case at Preston, in which carbolic acid was successfully employed. In neither of these instances did the epidemiologist meet the slightest difficulty in obtaining what he wanted. It follows, therefore, that had murder, instead of suicide, been in contemplation, the means would have been equally within reach. That being the case it certainly seems that scheduling some poisons, and leaving others equally deadly unscheduled, savours of the farcical. The question is, why should we be subjected to this reform, we suppose, would be howled at by the trade as undue interference with commercial freedom."

ROYAL INSTITUTION.—A General Monthly Meeting of the members of the Royal Institution was held on Monday, April 1st, Sir James Crichton-Browne presiding. The following were elected members:—Mr. Lockett Agnew, Dr. Julius Althaus, Mr. H. H. Dobree, and Mr. James M. Johnstone.

THREE TOWNS JUNIOR CHEMISTS' ASSOCIATION.—The council meeting of the Plymouth, Devonport, Stonehouse, and District Chemists' Association (Junior Section) was held at the Foresters' Hall, Octagon, on Thursday, March 28, when those present included Messrs. A. Barber, B. Buckner, H. Cantle, E. T. Cockes, T. Darke, A. V. Dewdney, F. Downing, E. W. H. Green, W. R. Vickers, and H. O. Westcott, Hon. Sec. The attendance of a large number of members made it a success. A motion that "further action must be taken with a view to the formation of a National Junior Section of the Pharmaceutical Society," was moved by Mr. John D. Turvey. The lecturer referred to the handsome materia medica cabinet presented by the Pharmaceutical Society, and open to students as being most advantageous to those preparing for their examinations. He expressed a hope that it would be well utilized. At the close of the meeting Mr. Turvey was heartily thanked for his very instructive and interesting lecture.
Technical Notes.

Ernest Beckman has suggested what he considers a useful datum in judging the quality of a milk—the taking of its freezing point; as this is only influenced by substances dissolved in it, and not those in a state of suspension. The higher the quality of the milk the lower its freezing point. His method of taking the freezing point is as follows: He surrounds the sample of milk, placed in a suitable vessel, with a mixture of ice and salt, and constantly stirs it with a thermometer until the point of solidification is reached. The temperature falls at first one or two degrees, but when the ice begins to separate it rises and remains constant for some little time, this period being taken as the freezing point. The thermometer he uses is graduated into one-hundredths of degrees, but as the addition of 10 per cent. of water to a milk only alters its freezing point five and a half hundredths of a degree, it would not be difficult to form an erroneous opinion of a sample.—Public Health.

In the report of chemical work of the U.S. Geological Survey just issued, a remarkable case is recorded of two spring waters from Missouri, both containing as a natural constituent zinc sulphate.

\[
\begin{array}{ccc}
\text{Zn} & \text{Ca} & \text{CO}_3 \\
\text{No. 1 contained} & 120.5 & 61.1 & 120.5 \text{ per million.} \\
\text{No. 2} & 132.4 & 63.1 & 110.0 \\
\end{array}
\]

A peculiarity of these waters was that all the CO\(_3\) was expelled by boiling. This is explained on the heating the ZnSO\(_4\) decomposes the CaCO\(_3\), forming calcium sulphate, zinc hydrate, or a basic sulphate and CO\(_2\). This would give rise to serious error in estimating the total solids in the usual manner.—Public Health.

The atomic weight of tungsten has been revised by Professor E. F. Smith, of the Pennsylvania University, and the specific heat of the pure metal redetermined. The mean value of the atomic weight derived from nine determinations, taking oxygen as 16, is 184-92. The highest and lowest values obtained differed by only 0.02 from this mean value. The mean of two series, 184.8, may be taken as representing a close approximation to the true atomic weight of tungsten. This value is considerably higher than the currently accepted one, 184-02, the number afforded by Clarke and Becker’s recalculation of the experimental results of various determinations. The atomic heat of pure tungsten obtained during the course of the atomic weight determinations has been ascertained by Professor Smith in conjunction with Mr. Grodseep, the final mean value arrived at for the specific heat of tungsten being 0.0356, a result closely agreeing with former determinations. The atomic heat obtained by multiplying the new value for the atomic weight by this number expressing the specific heat is 6.20, a value in close accordance with that usually accepted as representing the constant of Dulong and Petit for the truly metallic elements.—Technical World.

Obituary.

Notice has been received of the death of the following:

On March 26, Charles Read, Chemist and Druggist, Liverpool. (Aged 50.)

On March 29, J. J. Welch, Chemist and Druggist, Kinver, Staffs. (Aged 49.)

Parliamentary News.

In the House of Commons on Monday last, Mr. Newdigate asked the Secretary of State for the Home Department if his attention had been called to the explosion of a gas cylinder charged with chlorate of potash which recently occurred at Finchamp Street Station, causing the death of John Holbrook, and whether steps could be taken to have cylinders that are used for such purposes properly tested and duly stamped, so that their strength might be known by the users.

Mr. Asquith, in reply, said he had inquired into this matter, and had been advised that scientific opinion differs as to whether the bursting of these cylinders is due to the pressure of oxygen upon an imperfectly welded steel tube or to traces of impure substances present in the oxygen. He proposed to refer the question for the opinion of two or three distinguished experts on such matters.

Poisoning Cases and Inquests.

Laudanum.—Arthur Birnie, aged 45, died on Saturday, March 23, at 36, Whittaker Street, Derby, from the effects of laudanum, taken in mistake for medicine. Verdict: “Deceased died from laudanum accidentally taken.”

Strychnine.—Joseph McDonnell, aged 18, died on Sunday, March 24, at 72, Stockbrook Street, Derby, from the effects of strychnine contained in a rat poison, self-administered. Verdict: “Suicide whilst temporarily insane.”

Laudanum.—John Dunley, aged 55, died on Tuesday, March 26, in the Bradford Infirmary, (Yorkshire), from the effects of laudanum, self-administered. Verdict: “Suicide whilst in a state of unsound mind.”

Foot-rot Liquid.—Frank Fox, a miller, died on Saturday, March 23, at Crosthwaite, from the effects of nitric acid, nitrate of mercury, and chlorides of iron contained in foot-rot liquid, taken in mistake for Seigle’s syrup. Verdict: “Death from misconduct.”

Oxalic Acid.—Henry Rollison, aged 54, died on Wednesday, March 27, at 5, Tichborne Street, Brighton, from the effects of oxalic acid, self-administered. Verdict: “Suicide whilst temporarily of unsound mind.”

Prussic Acid.—Eric Hamilton, aged 32, died on Thursday, March 28, at Hyde Park Road, near Plymouth, from the effects of prussic acid, self-administered. Verdict: “Suicide whilst of unsound mind.”

Spirit of Salt.—A man named Carpenter, living at Lant Street, Borough, died on Saturday, March 30, in Guy’s Hospital, from the effects of spirit of salt taken in mistake for beer.

Vitriol.—Thomas Wilson, a herb seller, died on Saturday, March 30, at Oldham Road, Manchester, from the effects of vitriol taken in mistake for cough balsam. Verdict: “Death from misconduct.”

Aconite and Belladonna.—Sarah Ann Ellison, aged 28, died on Wednesday, March 27, at 2, Palmer Lane, York, from the effects of aconite and belladonna contained in a liniment. Verdict: “Deceased took the liniment containing aconite and belladonna by mistake whilst in an advanced stage of consumption.”
Carbolic Acid.—Cordelia Kesley, a parlourmaid, died on Tuesday, March 26, at West Lodge, Putney Lower Common, from the effects of carbolic acid taken for indigestion. Verdict: "Death from misadventure."

Spirit of Salt.—Joseph Pulham, died at 23, Blundell Street, Caledonian Road, London, from the effects of spirit of salt. At the inquest held on Friday, March 29, a verdict of "Death by misadventure" was returned.

Spirit of Salt.—Ismao Waits, aged 52, died on Tuesday, March 26, in the Queen's Hospital, Birmingham, from the effects of spirit of salt, self-administered. Verdict: "Suicide during temporary insanity."

EDINBURGH DISTRICT CHEMISTS' TRADE ASSOCIATION.

A meeting of the Association was held in the Pharmaceutical Society's House, 36, York Place, Edinburgh, on Thursday, March 28, at 11 a.m., Mr. Peter Bon, President, in the chair.

The minutes of last meeting were read and approved.

Mr. W. Charles Baker was elected a member and Mr. J. Rutherford Hill an honorary member.

PRESCRIBING PROPRIETARY MEDICINES.

The meeting then proceeded to consider a draft circular to medical men on the subject of prescribing proprietary medicines, which had been drawn up by the Committee.

Mr. D. MacLaren said before going any further he thought they should consider whether or not such a circular should be sent out. He had never heard that the Inland Revenue authorities had interfered in any case where a chemist had dispensed a proprietary medicine alone and without admixture when it was prescribed by a medical man, and he did not think they ever would do so. He did not think they should raise this question at all. They would only bring trouble on themselves. They were perfectly free at present, and he would have no hesitation in breaking an original bottle to supply any of these preparations if a doctor prescribed it. He was speaking from an experience of about forty years, and he felt very strongly that they should take no action. Many of them would remember the time when it was quite common to open bottles of Dr. Collie Brown's chlorodyne in this way, and yet there never was any prosecution. If they raised this question they would have themselves to blame for bringing a horns' nest about their ears. He would move that they take no further action in the matter.

Mr. Noble seconded the motion.

Mr. McDougall said he thought they ought to send this circular for the guidance of medical men. The makers of proprietary medicines were themselves taking steps to enlighten medical men on this subject. He therefore moved that the circular be sent.

Mr. Bowman seconded Mr. McDougall's motion, and said no doubt the Inland Revenue would soon get to know, if they did not know already, that these things were prescribed, and he did not think they should wait for a prosecution.

Mr. Bon said this proposal might have the effect of stopping the practice of prescribing these proprietary articles.

Mr. Henry, secretary, said this subject was first brought up by Mr. Macpherson, who said he objected to doing an illegal thing, and on this ground urged that something should be done to get over the present difficulty.

Mr. Forret asked what Mr. MacLaren would do if he got a prescription for, say, two ounces of Fellows' Syrup.

Mr. MacLaren said he would give what the doctor ordered, and would supply it out of an unstamped bottle so long as the Government tolerated the practice.

After further discussion a vote was taken, and by a majority of 5 to 1 it was agreed to send the circular in accordance with Mr. McDougall's motion.

After some slight alterations on the original draft, the following circular was approved of and ordered to be sent to all medical practitioners in the Edinburgh district:

THE EDINBURGH DISTRICT CHEMISTS' TRADE ASSOCIATION.

Dear Sir,—We are requested by the members of this Association to ask the attention of the Medical Profession within the District to a difficulty which exists in connection with the Prescribing of Proprietary Medicines, which are subject to Inland Revenue Stamp Duty, when sold to the public.

Certain of these medicines are, by a concession of the Board of Inland Revenue, exempted from stamp duty for dispensing purposes, provided that they be not dispensed alone, but as part of a medicine.

To each original bottle of such Proprietary Medicines (of which Fellows' Syrup, Battle's Bromidia, Parke, Davis and Co.'s Cascar Aromatica are familiar examples) a label such as the following is attached:

The contents of this unstamped package are not to be used in any other manner than as a component part of a medicine, in accordance with a prescription of a qualified medical practitioner.

The effect of this is that when a chemist is called upon to dispense a prescription for say—

"Syrup, Hypophos. Co. (Fellows) .... 3½l."

he is legally required to put over the cork a medicine stamp, in accordance with the monetary value of the Syrup. If, in order to avoid making apparent to the patient the character of the medicine, he should dispense it without the Stamp, he renders himself liable to a penalty for so doing.

We respectfully suggest that when a Medical Practitioner desires to prescribe a medicine of the kind in question, this difficulty in regard to its dispensing can be obviated by prescribing it in combination with something else, however small in quantity. For example:

(1) B. Syr. Hypophos. Co. (Fellows) .... 3½l.

B. Aurant. .... 3½l.

(2) B. Bromidia (Battle's) .... 3l.

Syrup .... 3l.

Each of the Proprietary Medicines in these two formulae is thus rendered "a component part of a medicine," and consequently in conformity with the Inland Revenue concession they may be dispensed by chemists without a medicine stamp being affixed to the bottle.

The above statements do not apply to Pharmacopoeial preparations such as:

Liq. Arsenicals (Fowler) .... 3l.

Apologising for troubling you in regard to this matter.

We are,

Very sincerely yours,

1, Bromdon Terrace, PETER BOA, Chairman.

Edinburgh. CLAUDE F. HENRY, Hon. Sec. April, 1895.

Messrs. J. A. Forret, and R. L. Hendry were appointed Auditors.
A discussion then took place as to the Annual Picnic, and it was remitted to the Committee with powers to make full enquiry and report to the next meeting of the Australian Pharmacopoeia. The members of the Committee thought of the keeping qualities of iodiform ointment, B.P., was touched upon, and the addition of a few drops of strong solution of caustic potash was a suggested preventative of change; and with the hope that suggestions from South Australia would be forthcoming, the lecturer closed an interesting address.

Mr. White moved that a hearty vote of thanks be accorded Mr. Barbour for his paper. To traverse the whole of it after forwarding it only a pleasure a matter of impossibility to a man with average memory, but he noted many suggestions of value, and hoped the members would have the opportunity of reading it at their leisure. He recognised the usefulness of the tables for gravities, solubilities, etc., and although the compilers of the new pharmacopoeia the Victorian Society caused him to have a very feeling towards that body he agreed that the omission of the name of a locality in connection with the first suggestion of the committee might be desirable. He would be very glad to see some remarks furnished to the compilers of the Pharmacopoeia of the British and South Australian Society. We ought, surely, to be able to do something in this direction. There were plenty of practical points, to say nothing of scientific ones, upon which the opinion of some members would be worth having. He hoped the Council would reconsider the matter, and he also hoped that Mr. Barbour's paper would be followed by others.

Mr. O'Connor, in seconding, was of opinion that the question of suggestions should be made an intercolonial matter. He regretted the want of interest that had been displayed, but he was pleased to note that Mr. Barbour's paper had somewhat revived it. He thought that united action of the colonies might bring about additions and alterations suitable to this part of the world. He thought that particular processes should be ignored. Suggestions might be made and debated and opinions formed, but to make a particular process paramount under the name of a person or persons or firms would, in his opinion, be very objectionable. He thought that any suggestion should come from the Society as a whole and all should work together.

Mr. Hill thought that if anyone suggested a better process than another he should have the benefit of it. He was looking forward with pleasure of reading the paper, and hoped it would be printed.

The Chairman cordially supported the vote of thanks. Mr. Barbour's valuable paper contained other matters than pharmacopoeial ones that might with advantage be discussed. Mr. O'Connor's remarks were in line with the policy that the Council considered it was opportune, and he could answer for that body that they would willingly reconsider it.

After some further remarks by Mr. Hill and Mr. White the vote was carried with acclamation.

Mr. Barbour thanked the members for the way they had received his paper. His object in putting the paper before the Society was the Society's benefit. He thought they might each take some preparation and specially study it with great advantage to the mutual good. In reply to Mr. O'Connor, he never proposed that any one preparation should be made official. The process he referred to was known in England as Faulding's, and he simply referred to it. He felt fully repaid for his trouble by the way his paper had been received.

Mr. White proposed that the Council reconsider the matter of pharmacopoeia suggestions. Mr. O'Connor seconded. Carried. 'A pleasant social gathering brought the meeting to a close.'
Patent Office Business.

PATENTS PUBLISHED MARCH 30, 1895.

Utilising spent pyrites (Mills, W.).—The residue from the burning of iron pyrites is powdered and passed over a magnetic separator to remove any ferrous sulphide and magnetic oxide. It is then mixed with 55 per cent. of salt and iron, and heated to dull redness. The ferrous oxide then forms a magnetic mass glued to metal by heating with carbon or in a current of carbon monoxide, or other reducing gas. For preparing ferrous oxide for pharmaceutical purposes, the impure ferrous oxide obtained by dilution of the sulphure in a current of carbon monoxide is precipitated with weak alkali, washed and dried first at 100°, and then at 350° C. The pure ferrous oxide so obtained is reduced by heating to redness after admixture with 55 per cent. of levigated iron. No. 5600 of 1894.

Crutches, etc. (Smith, W. R.).—The ends of crutches, wooden legs, etc., are provided with a ferrule fitted with a leather or other shoe, and containing a spiral or other spring to afford a ball and alabaster ball, whereby the crutches are prevented from sliding when striking the ground. No. 6429 of 1894.

Potassium cyanide (Mackey, W. McD., and Hutcheson, J. F.).—The cyanide is produced by heating by means of an air blast in a cupola or other furnace, a mixture of coal or other carbonaceous matter and potassium carbonate. The mixture is fed in continuously, and the cyanide which is formed at the “hot zone” by the action of the atmospheric nitrogen, passes in the form of vapour through a lauter and condensed. No. 6996 of 1894, prepared for industrial use.

Thermometers (Kent, J.).—Refers to an improvement in patent No. 19,199 of 1890, and relates to a form of scale clad in a flattened passage in the thermometer bulb behind the element of the column. The ordinary enamelled scale is replaced by one of mice, the back of the thermometer being enamelled, but sufficiently transparent for the graduations on the scale to be read when held up to the light. No. 8480 of 1894.

Plating and soldering aluminium (Ramage, H.).—Aluminium is coated with metals or alloys which retain their lustre in the air, or surfaces of aluminium are prepared for soldering, by rubbing upon it an alloy which consists preferably of zinc with tin or cadmium, or both in stated proportions. These alloys are found to deposit crystals and become pasty at a much higher temperature than the true soldering point, and if rubbed upon aluminium while the crystals are separating, will adhere with it and give a good surface when further heated and polished. Surfaces of aluminium so prepared may be soldered with more of the same composition, or with other metals of 1894.

Treating spinal fractures (Despres, E.M.).—The invention relates to a couch or portable platform, on which the patient lies. Suitable appliances permit adjustment of the patient, and trap-doors arranged at intervals allow of the necessary dressings, etc., being done without moving him. No. 9726 of 1894.

Sodium bicarbonate (Cranev, T.).—This salt is produced by the electrolysis of common salt solution. The electrolytic vats, each comprising an anode chamber and a cathode chamber as usual, are arranged in a connected series of different levels, so that the salt shall overflow from each anode chamber into that of the vat below, and the caustic soda solution produced by the electrolysis shall similarly circulate from the cathode chambers. The caustic soda solution is finally treated with carbonic acid gas in a long “standpipe” or cylinder, so that bicarbonate of soda is formed. The crystals formed are filtered and liquor returns to the electrolytic vats. No. 9979 of 1894.

Peptonised milk beverage (Bernstein, A.).—To prepare this, skimmed milk or butter-milk is sterilised, treated with a preparation containing a certain bacterium whose growth is checked, and the prepared milk is then maintained at 20° C. for a few days. It is then added to more milk, and the treatment is repeated until enough has been peptonised. The casing is said to be converted into peptonised milk, and the liquid when boiled in a vessel is filtered, and is then called “galacton” by the inventor. It is ferments by means of the yeasts which are used for milk sugar by Duciaux and others, usually after addition of cane sugar, and the product is sold as a beverage. No. 10,105 of 1894.

Telephrasing and emulsifying medicaments (Cowen, W. B.).—The invention comprises a machine turned by a treadle or otherwise for grinding and mixing solid or liquid medicaments with water, oil, etc. The materials are contained in a revolving, open-topped chamber containing two elements, the grinding stones, the weight grinds the materials, and it is then emulsified as to mix them and direct them beneath the stones. No. 18,982 of 1894.

Sewage belts (Thompson, W. P.), communicated from Tufnell, W. J.).—The portion which requires renewal is made detachable and of sufficiently simple construction to be cheaply replaced. It consists of a single piece of woven material with an opening for the penis. The leg straps are removable, and are formed of indiarubber tubing. No. 23,688 of 1894.

Food-product from blood (Finson, O.).—“Hemalbumen” is obtained from blood by diluting it (after it has been freed from fibrin by whipping) with water containing a small quantity of citric acid. The mixture is heated to about 60° C. for fifteen minutes, and the coagulated albumen is filtered off, washed, dried at 45° C. in vacuo, and ground to powder. It is said to form a nutritious food in times of scarcity. No. 21,735 of 1894.

Preparing carbon for filters, etc. (Brandenburg, O. W., and Pott, F. H.).—Carbon for filtering water, and for general chemical uses, is prepared by heating conglomerates of wood, lignite, gnos, or bituminous coal, with a mixture of means of superheated steam or otherwise, with careful exclusion of air. After cooling to about 350° F., the residue is broken into lumps and treated with concentrated sulphuric acid, which completes the carbonisation and removes all impurities. It may be further treated with hydrochloric acid. It is finally washed, dried, and powdered. No. 2293 of 1895.

Trade Marks Applied For.∗

No. 185,996.—“SPIERRON.”—Chemical substances prepared for use in medicine and pharmacy.—Spier and Pond, Limited, 26, New Bridge Street, London, E.C. February 14, 1895.

No. 185,956.—“LINE.” and device; A group of bronze in solid; chemical substances used in manufactures or philosophical research, and anti-corrosives.—Actien Gesellschaft Georg Egestorf’s Salzwerke, Chemical Works, Lenden, near Hannover, Germany. January 23, 1895. The essential particular is the device, the mark, and a label.

No. 158,701.—“THE CLEANSING DRENCH” and name and address of applicants on a label.—Chemical substances used for veterinary and sanitary purposes.—Corbyn, Stacey and Co., 300, High Holborn, London. November 16, 1894.

No. 185,896.—“TOMPO.”—A drug for repelling moths from garments.—Ann Littlejohn Pantyer, 43, Langham Road, West Green, Middlesex. February 6, 1895.

No. 155,789.—“XL ALL LIQUID MANURE” and “XL ALL TOBACCO POWDERS,” with device; A liquid manure, being a chemical substance included in Class 2, and tobacco powder, for destroying, removing, and preventing insects and blight on plants and trees, being a vermin destroyer included in Class 2; address, 14 George Street, Wholesale Market, London, E.C. By Wharf, Lambeth, London. February 21, 1895. The essential particular is the device of the vine-leaf.

No. 185,703.—“CONF. OPII” and name and address of applicants on a label.—Chemical substances prepared for use in medicine, pharmacy, and dressing wounds.—Stacey and Co., 300, High Holborn, London. November 16, 1894.

No. 181,147.—“COCA TONIC CHAMPAGNE” and applicants’ signature and address.—Coca Tonic champagne, being a medicated wine for human use, is particular to the person, Perrier and Cie, Bauxy près Reims, France, and 106, Fenchurch Street, London, E.C. December 7, 1894. The essential particular is the applicants’ signature.

∗ Compiled from the Trade Marks Journal.
Remedies Introduced in 1894.*

Acetogen.—Used in manufacturing vinegar.

Acetone (not “Acetone”).—Grip and headache remedy.

Acetoneresorcine.—Combination of two molecules of resorcin and one of acetone.—Antiseptic.

Acid Glycogenophosphoric.—(HO)₃PO.OC₂H₄.OH.

Nervine.

Adonis Extractiva, Tincture.—Anti-fat remedy.

Alodyne.—Proprietary tooth tincture.

Alcohol.—Salicylic ether of alpha-naphthol.—Internal antiseptic, like salol.

Alumninum Borosilicate.—Disinfecting astringent.

Aromaline.—Derivative of the Amino-phenyl series.—Stimulant, analgesic and antipyretic.

Amylobarbot.—Mixture of nine parts of carbolic acid soap (160), amylic alcohol (160), and water (681).—Antiseptic.

Anadol.—Proprietary antiseptic and analgesic.

Analgies.—Tablets containing acetanilid, ammonium chloride, caffeine and sodium bicarbonate.—Analgesia.—("Analgesin" is a French synonym of antipyrine).

Analgine.—Proprietary analgesic and antipyretic.

Analgine-Laborb.—Another proprietary analgesic.

Anodyne.—Proprietary analgesic.

Anodin.—Proprietary ophthalmologic anesthetic.

Antalgia.—Proprietary antipyretic and analgesic.

Antiflu.—Proprietary disinfectant.

Antipyrine.—Proprietary pain reliever.

Antidiptheritikon.—Balsam mixture of oil birch (5), oil balsam (95), potassium carbonate (1), and potassium sulphide (1).—Diphtheria remedy.

Antidol.—Proprietary pain reliever.

Antidolor.—Proprietary anodyne.

Antifer.—Proprietary deodorizing powder.

Antipyrin.—Sodium tetraborate, soluble.

Antipyrin.—Proprietary anodyne.

Antipyrine.—“Coal tar derivative.”—Proprietary antipyretic and anodyne.

Antirheumatin.—Mixture of sodium salicylate and methylene blue.—Antirheumatic.

Antitoxin.—"Quinine derivative."—Anodyne.

Antithormone.—Proprietary febrifuge.

Antitoxin.—Proprietary antipyretic and anodyne.

Antitoxin.—(Not to be confused with the generic term “Antitoxin,” the blood serums of immunized animals).

Apodyne.—Proprietary anodyne and antipyretic.

Arcosina Hydrotropale.—Salt of alkali from arcos cacauma.—Laxative in veterinary medicine.

Arench.—Proprietary dental anesthetic.

Athana.—Proprietary disinfectant.

Atrocin.—Ammoniated pyrogallol solution.—Hair dye.

Baellia.—Proprietary deodoriser and disinfectant.

Bacine.—Proprietary “yeast cure for phthisis.”

Bensactine.—Acetamidomethylsulphonic acid.—Antiseptic.

Antineuralgic.

Bismuth Naphthol Hydrate.—Chaplin’s antiseptic.

Bismuth Sulphocarbonate.—Antiseptic astrigent.

Boral.—Aluminum borotartrate.—Disinfecting astrigent.

Bovylol.—The result of the action of boric acid (25) upon sodium salicylate (32).—Antiseptic.

Braclom.—Proprietary headache remedy.

Bromalin.—Bromethyliormin.—Antiepileptic.

Calcium Glycinephosphate.—CaH₂.P₂O₄.—Nervine.

Catecol.—Mixture of calomel (1), bismuth sub-nitrate (1) and lactose (8).—Intestinal disinfectant.

Canabinon.—Narcotic principle obtained from cannabis indica.

Cannadion.—Proprietary disinfectant.

Capitrons.—Proprietary antipyretic and antineuralgic.

Caroline.—Coal tar disinfectant.

Charma.—Antiseptic.

Chloral.—Proprietary remedy like bromidina.

Chloridol.-P—Chlorine, substitution product of phenol, cresole and guaialcin.—Inhalation antiseptic.

Chromam.—Parasiticial dermat.

Chromos.—Chloryd sodium sulphite and sulphate.—Disinfectant.

Colla.—Schiff’s skin varnish.

Corticil.—Glucose from cortonilla scrofulosum.

Cardio.—Cardiac.

Cryostase.—Mixture of equal parts of carbolic acid, camphor, and saponin, with traces of tartrentine oil.—Becomes solid when heated, and liquid when cooled to below 0°C.

Cystallerine modified.—Solution of pyroxylin (1) in a mixture of methyl alcohol (4) and amyl acetate.

Dermic.

Cutol.—Aluminum borotartrate.—Disinfecting astrigent.

Cutol Soluble.—Aluminum borotartrate.

Dermel.—Bismuth chrysophanate.—Astringent dermat.

Dermolin.—Proprietary ointment-base (soap).

Diprophyl.—Quinacetol; Orthodoxquinolinemeta-sulphonic acid.—Internal antiseptic.

Divom.—Disinfectant.

Dioctoform.—Tetra-iodoethylene.—Antiseptic.

Diphtheriticide.—Pastilles of thymol, sodium borosate, and saccharin.—Propylasotic against diphtheria.

Eumol.—Paraffin oil oxidised under pressure.

Emulsifier.

Entomophobe.—Insect killer.

Erythrin.—Glucoide from erythia moschata.

Forcel.—Proprietary anodyne and antipyretic.

Ferrubol.—“Coal tar product.”—Anodyne and anti-rheumatic.

Ferralis.—Compound of iron extracted from the liver of the hog. Contains 6 per cent. Fe.—Hematinic.

*(To be continued.)*

Publications Received.

**CLINICAL LECTURES ON THE PREVENTION OF CONSUMPTION.** By WILLIAM MURRAY, M.D., F.R.C.P. Pp. 103. Price 3s. 6d. London: Ballière, Tindall and Cox. From the Author.

Notes and Queries.

CLEANING CLOTHING.

[826.] Turpentine, ammonia, and water are the chief ingredients in preparations supplied for washing purposes. A small proportion of methylated spirit is sometimes added with advantage. According to the Scientific American, Mullerison's preparation is a mixture of turpentine, 23½ parts; ammonia solution, 19 parts; methylated spirit, 25 parts; ether, 2½ parts; acetic ether 2½ parts; and water, 25 parts; all by weight.

INK FOR RUBBER STAMP PADS.

[826.] Inks suitable for typewriters serve equally well, with slight modification, for stamping pads. Thus oil-soluble aniline colours, when dissolved in castor oil, answer for either purpose. A modification of a typewriter ink recently given (Scrip., p. 107) may be used, and is as follows:—Castor oil, 4 parts; cresote or carbolic acid, 1 part; cassia oil, 1 part; and oil-soluble aniline colour, 1 or 2 parts. As a rule, however, oily inks are unsuitable for rubber stamps, those prepared with glycerin being preferable. A general formula for the latter is as follows:—Aniline colour, 1½ oz.; boiling water, 1 oz.; methylated spirit, 6 oz.; glycerin, to make 1 lb. Mix in the order given. Half of the glycerin may be replaced by treacle. The spirit is necessary to ensure rapid drying.

LIME CREAM.

[827.] An inseparable preparation may be made by shaking almond oil, 5 lbs., with liquor potassae, 2½ oz., in a clean, dry bottle. Then gradually add in small quantities at a time, water, 8 to 12 lb. oz., according to consistence required, and shaking after each addition. Finally add fresh essence of lemon, 4½ oz., and after again shaking the preparation will be complete.

NUTRIENT GELATIN.

[828.] To prepare this, first make beef broth by mincing 450 gm. of lean beef, free from all fat and connective tissue, and boiling for half an hour in a large flask, with a little of distilled water. Filter and make up to one litre with water, then add sodium chloride 5 Gm., and pure peppermint, 10 Gm. Heat the mixture in a flask, on a water bath at 100°C, for an hour, shaking from time to time. Now cautiously add concentrated solution of sodium carbonate until faintly alkaline, and again heat at 100°C for half an hour. Next allow 100 to 120 Gm. of sheet gelatin to soak in the broth for half an hour, then boil, stir slowly on a water bath until the gelatin is dissolved, neutralise carefully, and again heat for half an hour. Then add the white of an egg, heat till all the albumin is precipitated, and finally filter through two layers of moist filter paper, on a hot water funnel, into sterilised flasks, and sterile sheets of steriliser for twenty minutes on each of two successive days.

BRONZE PAINTS.

[829.] In mixing the so-called gold and silver paints, it is necessary to carefully avoid the least trace of acidity in the medium. This consists preferably of mastic or dammar dissolved in a large proportion of benzol. Neutralisation may be effected by heating the crushed resin with dried sodium bicarbonate until effervescence ceases, then dissolving and filtering; or, the varnish may be shaken with liquor potassae after solution is effected, and carefully decanted after separation has taken place. Add a quarter of an ounce of the finest bone powder to each fluid ounce of medium, and shake each time before use. Another medium that gives good results is a solution of pyroxylin or celluloid in amyl acetate and acetic. It should form a perfectly transparent film when dry, and not be kept too long, since, like colloidin, it tends to solidify under certain conditions.

Trade Correspondence.

[Under this heading the Editor proposes to publish letters dealing more especially with the trade aspects of pharmacy. Correspondents should write on one side of the paper only, and send with them whether it will in any way affect their interests. From the peculiar nature of our calling it is one the management of which must be left entirely to the discretion of the proprietor, so that the majority would hail with satisfaction an opportunity of obtaining a weekly half holiday, there may be instances where such a proceeding might be attended with very serious results to one business, whereas a neighbouring business, owing to a different class of trade, would be little affected. Even if only on the ground of resisting encroachment on individual liberty this measure should be resisted; grandfatherly government is going too far. Imagine the store chemist of a neighbourhood desiring to take a half holiday on a certain day of the week, which they could do without any detriment to their business, and compelling a neighbouring pharmacist who is entirely dependent upon its supremacy to be summoned to the police court for the fixed hour of penalty of dragging him into the police court. Would the plea that we are "professional men," not "traders," hold?]

AN INTERESTED PERSON.

EVALUATING SHOPS.

Sir,—Chemists seem to regard the Shop Early Closing Bill with apathy, but the publication of your note on the matter (ante, p. 80) may make them either whether it will in any way affect their interests. From the peculiar nature of our calling it is one the management of which must be left entirely to the discretion of the proprietor, so that the majority would hail with satisfaction an opportunity of obtaining a weekly half holiday, there may be instances where such a proceeding might be attended with very serious results to one business, whereas a neighbouring business, owing to a different class of trade, would be little affected. Even if only on the ground of resisting encroachment on individual liberty this measure should be resisted; grandfatherly government is going too far. Imagine the store chemist of a neighbourhood desiring to take a half holiday on a certain day of the week, which they could do without any detriment to their business, and compelling a neighbouring pharmacist who is entirely dependent upon its supremacy to be summoned to the police court for the fixed hour of penalty of dragging him into the police court. Would the plea that we are "professional men," not "traders," hold?

MINIMUM CUTTING PRICES.

Sir,—Many years ago I endeavoured to point out to your readers the futility of cutting prices, and had the principles I then tried to inculcate been more generally carried out, I venture to think that the retail trade of to-day would be in a more satisfactory condition.

While thoroughly appreciating the various efforts of manufacturers to maintain prices and allow fair profits to the retailer, I am inclined to agree with Mr. Allen on the question of giving free trade principles their due, and should prefer not to be harpered with agreements, feeling that so far as the control of retail prices is possible the best plan to prevent cutting and maintain a fair uniformity is for proprietors to make so little difference between wholesale and retail prices as to practically leave no margin for underselling, and if at the same time they should exact normal amounts for the sale of an article being sold at any price but that at which it is advertised is quite done away with.

Where I think so many make a mistake is in trying to make rules which are only applicable to purely trading concerns up to the business of a chemist and druggist, a calling differing from all others in that it consists of such a strange and inseparable mixture of trading and professional duties, its duties naturally expecting more than a grocer's price for the same article under different circumstances and conditions. I fail to see how the accomplished pharmacist of the rising generation can care to deal in articles that any oilman can, and does, sell and be content with the same profit.

Therefore it seems to me that the only way out of the difficulty is to give up such unprofitable transactions, and though in these views I fear I am largely in the minority, I cannot help thinking that pharmacists should have the boldness to relinquish at least such trading as is carried on only as a baa to bring other business, for I fancy that the artifice cuts both ways, the public finding us playing tricks in selling soap may give us credit for employing similar tactics in dispensing medicine. The fact of huge drug stores opening in all directions makes our business more difficult than ever, but, speaking generally, my own impression is that goods which can be sold at either a minimum or a medium profit, is the rule rather than the exception when handling at all, especially when it is borne in mind that such small profits are very conducive to commercial trickery of one kind or another.

20 Boundary Road, N.W.

J. J. CHAPMAN
PHYSIO-CHEMISTRY.

The recognition of the importance to the pharmacist of some knowledge of physics is a matter of very recent date; and even now probably very many would be inclined to regard such knowledge as more ornamental than useful. That the value of the subject is being recognised, however, is shown by the fact that in the Major examination a distinct paper is set in physics, and as much time is devoted to this subject as to chemistry, botany, or materia medica, so far as the written portion of the examination is concerned. Nevertheless, it may be advisable, before proceeding to discuss any physical operations, to point out clearly the relationship of this branch of knowledge to those others, the importance of which to the pharmaceutical chemist will at once be admitted.

The term physics includes the well-defined sciences of heat, optics, acoustics, and electricity and magnetic branches of knowledge all touch or overlap each other at their borders, so do they also touch on the science of chemistry; and it is to the touching or overlapping regions of those sciences with chemistry, and to a number of matters connected with chemistry, and not falling under any of the above heads, that the term physico-chemistry may be suitably applied.

The science of chemistry is every day making advances along the line of our knowledge of the quantitative aspects of chemical change. The introduction of the balance into chemical work by Lavosier, which led to the determination of the quantity of each of the substances taking part in a chemical change, produced a revolution in the attitude of chemists to the reactions they studied, and laid the foundation of modern chemistry. But a scarcely less notable revolution has been gradually taking place in late years, and chemists now recognise the importance of also determining quantitatively the non-material factors of chemical actions, as for instance, the amount of heat produced or absorbed, and measuring accurately such properties of chemical substances as the power of refracting light, etc. The arrangement of the known chemical elements in the "periodic table" of Mendelejeff has done much to bring to light the fact that there exist well-defined relations between the atomic weights of elements and all their other properties, including such as density, colour, conductivity, specific heat capacity, etc., usually called physical. In the case of compounds, very many of these properties depend directly on the nature and arrangement of the atoms composing the molecule; and consequently much work has been done and much more remains to be done in measuring the physical properties of elements and of large groups of compounds; the actual experiments necessary being usually, though not always, strictly physical, while the end in view is a purely chemical one, namely, the gaining of an insight into the qualities and "power of doing" of particular species of matter. It is impossible to fully appreciate or understand this department of chemistry without some knowledge of the processes that have to be carried out, and the importance of this branch of the subject is such that no one can claim to have much knowledge of chemistry who has omitted to acquaint himself with it.

But it is not only for the sake of its bearing on chemical theory that the pharmaceutical chemist should have a knowledge of physico-chemistry. In the ordinary every-day operations of pharmacy and practical chemistry, physical measurements are of constant occurrence, and for their adequate performance something more than a mere mechanical knowledge of them is necessary. In addition, the necessity for exactitude which is so characteristic of all physical operations that are to have scientific value, provides excellent discipline for the pharmaceutical student.

Two of the operations most frequently performed by the pharmacist belong strictly to the domain of physical measurements, namely, the measurement of volume and the measurement of weight or mass; and although it is generally not necessary that they should be performed with the same accuracy as when they are to form the basis for exact theoretical considerations, yet a full practical knowledge of the conditions affecting their correctness is of great value, and it is with these operations that a pharmacist is commonly called upon to perform, that belong to the category of physical measurements, may be mentioned determinations of melting and boiling points, of specific gravity, solubility, specific rotatory power, etc. In what follows the determination of some of these quantities will be described in some detail.

WEIGHING, OR MEASUREMENT OF MASS.

The most fundamental of all measurements is the measurement of mass. The mass of a body in terms of a fixed unit, the gram or equivalent, by instance, is ascertained by comparing the action of gravitation on the two, which is what is called weighing. The mass of a body is proportional to the attraction exerted on it by the earth. In weighing, therefore, it is important that the actual gravitative forces acting on the body under experiment and on the standard mass should be compared, and any opposing force, such as the buoyancy of the air, which acts unequally upon them, will give rise to an error which must be got rid of. As a first essential to exact weighing, a reliable and solid balance must be used. The short-beam instruments that are now coming into general use are much to be commended, as they can be made quite as accurate as those with long beam, and the time occupied in weighing with them is much less. They are also less expensive. If the arms are not absolutely the same length, the weighing should be by substitution; that is, the body to be weighed is placed in one pan and counterbalanced by any suitable material in the other; it is then removed and replaced by weights until equality is again reached; the weights that have now been put on, of course represent the true weight of the body, subject to the condition mentioned below. Weighing should always be by oscillation, that is, the balance is allowed to swing gently, and equilibrium between the arms with their loads is reached when the distance to which the pointer swings on one side of the zero is intermediate between the distances to which it goes in the preceding and succeeding swings on the other side. The pointer moves close to the fulcrum so that the readings are facilitated. Very small weights are not placed on the scale-pan, but are given by means of a little wire weight, the rider, that slides along one arm of the beam and

Vol. LIV. (Third Series, Vol. XXV.), No. 1294.
represents different weights according to its position as read on the graduated beam.

If the substance that is being weighed has a low specific gravity, or is contained in a large closed vessel, the volume of the air that it displaces will be much greater than the volume of that displaced by the weights that counterbalance it, and it will consequently be more supported by the air, and its apparent weight will be less than is correct. This may be overcome in some cases by using among the weights that counterbalance it some body that has as nearly as possible the same volume. If, however, this cannot be done the apparent weight must be corrected as follows. The difference between the true weight and the apparent weight is the weight of the air that it displaces, that is, of a volume of air equal to its own volume. The volume is found by dividing the weight of the body (the apparent weight is sufficiently correct) by its specific gravity; if the weight is in grammes this gives the volume in cubic centimetres. Multiplying this volume by 0.01 (the weight in grammes of 1 c.c. of air under ordinary conditions), we obtain the weight of air displaced; this is added to the apparent weight of the body. Similarly the weight of the air displaced by the weights is calculated, and that of course is deducted from the apparent weight of the body. In this way its weight in a vacuum is found.

It is here assumed that the weights used have actually the values assigned to them by the makers, but this is frequently not the case. The errors of the weights must be determined by comparing them with each other by weighing, and so establishing fixed relations between them all. If one of them can then be compared with a standard, the others are, of course, all referred to this one. When this cannot be done the assumption is made that the sum of all the weights has actually its nominal value; this is a safe assumption, as the errors will in general be as often on one side as the other, and any small error that is not so compensated is quite unappreciable when divided among the whole set. By finding what fraction of the whole is formed by each individual weight its nominal value is obtained; this is recorded and used in actual work instead of the nominal value. Fuller details of the corrections here referred to are given in Kohlräusch's 'Introduction to Physical Measurements.'

Correction of Apparatus.

In general, it may be said that for any accurate physical measurements the apparatus used must first be tested and the necessary corrections ascertained. The graduations on a burette, for instance, while almost always sufficiently correct for ordinary volumetric analysis, require careful correction when very accurate results are required. Since weight is one of the best defined properties of matter, and admits of very accurate measurement, corrections are made whenever possible by a method of weighing. Calibration of a burette is accordingly carried out by weighing the quantity of mercury or water that occupies apparent unit volume (1 c.c. or 2 c.c.) at every different part of the tube.

Another correction that is more frequently required is that of a thermometer when accurate temperature measurements are necessary, as in the determination of melting points and boiling points. The errors to which the readings of a thermometer are liable arise from two sources. In the first place the bore of the tube is scarcely ever of the same diameter at all parts of the stem, so that 'equal lengths of the stem will not contain equal quantities of mercury, and since the degree marks are usually at equal distances an error arises from this fact. Secondly, the bulb of a thermometer undergoes a slow contraction for a long time after it is made, so that if the freezing and boiling points were correctly marked in the first place, they come to be incorrect, and this error may even amount to several degrees.

In correcting a thermometer the true temperatures corresponding to a number of readings of the mercury at different parts of the stem are ascertained, and the corrections for intermediate points are made by the method of interpolation, which will be described hereafter. The direct corrections may of course be made by comparison with a standard instrument in a suitable bath; but a standard thermometer is not always at hand, and another plan must be adopted. The method here given is that of Hällström, and is mainly taken from Ostwald's 'Physico-chemical Measurements.'

Let us suppose we require to correct a thermometer from 0° to 100°; we leave the correction of these two points till afterwards, and proceed to ascertain the error due to inequality of the bore. To do this it will be necessary to separate successively from the rest of the mercury, threads of approximately the lengths 20° and 25°. This is managed as follows. Warm the bulb so that the mercury begins to rise in the stem, then invert the thermometer and give it a smart tap at the end on the table. In this way a thread of mercury is separated, which will in general not be of the required length. Now warm the mercury in the bulb until it rises and joins the detached thread, and note the point on the scale at which the union takes place; warm or cool the bulb until the height of the mercurial column is just 20° above that point, invert and take another thread, until the length required will be separated. The exact length of this thread has now to be found in different parts of the tube. The thermometer is fixed to a piece of board by strips of indiarubber, and put in a horizontal position. The exact positions on the scale of the ends of the mercury thread are read by a lens fixed on the three legs; to avoid parallactic error, the lens is covered except a small portion in the centre, or two parallel hairs are stretched across it, one above and one below, and these must appear to coincide with one another and with the end of the mercury. One end of the thread is now brought to 0° by gently tapping in a vertical position, and the exact position of the other end is found. Similarly its length is found starting from 20°, 40°, 60°, and 80°. These lengths will in general not be the same, and will differ a little from 20°. If we subtract 20 from each, and take the mean of the five remainders, the result is the amount by which the length of the thread taken exceeds the fifth part of the distance from 0° to 100°. Deduct this mean excess from each of the first four direct readings; the results give correctly corresponding to one-fifth of the distance from 0° to 100° in the different parts of the tube, and from this the true points 20°, 40°, 60°, 80° are easily obtained. An
example will make this clearer; let the following be the measurements obtained:

<table>
<thead>
<tr>
<th>From</th>
<th>Length</th>
<th>Excess over 20° equals</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 to 2</td>
<td>21.2</td>
<td>21.2</td>
</tr>
<tr>
<td>20</td>
<td>40.8</td>
<td>20.8</td>
</tr>
<tr>
<td>40</td>
<td>61.0</td>
<td>21.0</td>
</tr>
<tr>
<td>60</td>
<td>82.5</td>
<td>12.5</td>
</tr>
<tr>
<td>80</td>
<td>100.9</td>
<td>20.9</td>
</tr>
</tbody>
</table>

The mean excess over 20° is thus $\frac{5.4}{5} = 1.08$

The apparent length of one-fifth of the distance from 0° to 100° will therefore be, in the respective portions of the stem:

<table>
<thead>
<tr>
<th>True temp.</th>
<th>Read temp.</th>
</tr>
</thead>
<tbody>
<tr>
<td>20°</td>
<td>20°12</td>
</tr>
<tr>
<td>40°</td>
<td>20°12 + 19°72 = 39°84</td>
</tr>
<tr>
<td>60°</td>
<td>20°43 + 19°23 = 39°66</td>
</tr>
<tr>
<td>80°</td>
<td>20°18 + 19°82 = 39°10</td>
</tr>
<tr>
<td>100°</td>
<td>20°18 + 19°82 = 39°10</td>
</tr>
</tbody>
</table>

Next measure with the same thread the distances 5—25, 10—30, 25—45, 30—50, 50—70, 55—75, 70—90, 75—95, subtracting from each distance read, the mean excess of the thread over 20°, in the example 1°0.8. Now shake the thread down to the bulb again, and separate a new one of length about 25°. By a method exactly like the above, find by how much this exceeds the true length of one-fourth of the distance from 0° to 100°, and fix the true points 25°, 50°, 75°. Also measure with it the distances 10—35, 15—40, 20—45, 35—60, 40—65, 55—80, 60—85, 65—90, using the corrected length of the thread as before. Having now fixed the points 20°, 25°, 40°, 50°, 60°, 75°, 80°, we use the remaining measurements to get other points from these. Thus we have:

| 5° = 25°—20 | 15° = 40°—25 | 30° = 50°—20 |
| 35° = 50°—25 | 45° = 55°+20, or 20°+25 |
| 55° = 75°—20 or 80°—25 | 65° = 40°+25 |
| 70° = 50°+20 | 85° = 60°+25, 95° = 75°+20 |
| 10 = 30°—20 or 35°—25 |

In all cases where a point is given by two independent measurements the mean is taken if they differ, and the closeness with which they agree is a measure of the accuracy of the work. We have now corrected the stem at points distant by five degrees; the corrections for intermediate points are found by interpolation.

It remains to correct the freezing and boiling points. If corrections are required above 100° the measurements of the threads are continued as far up the stem as necessary, and the corrections so obtained. To find the true freezing point, the thermometer is clamped vertically in a vessel containing pounded ice, standing in an outer vessel containing ice and water. Care must be taken in reading with a lens to avoid parallax; several readings are taken at intervals of a few minutes, and the position of the mercury must remain unaltered, or the determination cannot be taken as satisfactory. To find the boiling point, the thermometer is fixed by a cork in the neck of a clean vessel in which distilled water is boiled, in such a way that the bulb and the stem almost up to the 100° division are in the stem; if great accuracy is required, there must be an outer vessel or jacket also containing steam, as in Regnault's hypsometer; for most purposes a distilling flask with a wide neck and a fairly long side-arm is sufficient. The top of the mercury column should be just visible above the cork, and its position is read with a lens. This will be 100° C. if the barometer indicates a pressure of 760 Mm. of mercury reduced to 0°. If the atmospheric pressure is greater or less than this, the boiling point found will be above or below 100°, and if the pressure is known the boiling point is found from the tables that are published. For small deviations from normal pressure, there is a change of 0°1 in the boiling point for every 2.58 Mm. in the height of the barometer.

If the corrections at 0° and at 100° are equal, it is only necessary to add (or subtract, as the case may be) this correction to all the corrections previously made for the stem. If the corrections at 0° and 100° are not equal, the correction at 0° is added as a constant error, and in addition, to each correction is added a fraction of the difference between the corrections of 0° and 100°, proportional to its distance from 0°. This is most conveniently done by the graphic method, as will be described hereafter.

*(To be continued.)*

**MODERN MATERIA MEDICA.**

The preface to this edition of Dr. Scolesby Jackson's *Materia Medica* contains certain explanatory statements, the consideration of which may contribute to a correct appreciation of the work itself. Thus, it is stated in the preface that

"The re-editing of this volume was begun several years ago by the late Dr. Moineet. The first portion was printed off from his revision, and in view of the probable appearance of a new edition of the British Pharmacopoeia, it has seemed best to the publisher that this part should be left untouched."

The present editors have therefore begun where Dr. Moineet left off, and have incorporated the addenda to the British Pharmacopoeia partly in the text and partly in an appendix. The text and scope of Dr. Scolesby Jackson's original work have been as little interfered with as possible, "so as to preserve the distinct individuality of the book," which is expected to "prove of special value to pharmaceutical students."

It appears, therefore, that the work is in more respects than one hybrid in its nature. Originally compiled by Dr. Scolesby Jackson, and subsequently edited by Dr. MacDonald, it has now been re-edited partly by Dr. Moineet and partly by Dr. Stockman, in conjunction with Mr. Rutherford Hill. Further, it is intended for the use of two classes of students, the medical and the pharmaceutical.
It is a question for serious consideration whether at the present time the endeavour to combine in one work such information concerning drugs as the medical student desires with such as the pharmaceutical student finds necessary is in itself well advised. Consider for a moment the changes that have been made since the publication, in 1866, of the first edition of Dr. Scoresby Jackson's 'Note-Book'—changes conspicuous enough in the pharmaceutical world during the last few years alone—and evidenced, if evidence be required, by the increased and increasing stringency of the examinations, an indication of the opinion entertained by leaders in pharmacy, that the pharmacist of the future should and must be far more intimately acquainted with the chemistry and pharmacognosy of the drugs he handles than has hitherto been considered necessary. The demands made upon the medical student have also grown, but in a different direction. To him the chemistry and pharmacognosy of drugs have lost much of their importance, whilst pharmacology and therapeutics have gained in more than equal proportion. From a pharmaceutical point of view, the desirability of separating pharmacy and materia medica, both inorganic and organic, to be dealt with by specialists, has long been recognised, and surely indications of a similar specialisation on the part of medicine are not wanting. Is it then desirable to retain the "distinct individuality," not of this work alone but of all similar ones, after the conditions that called them into existence have undergone such radical changes?

It will be interesting now to turn to the volume itself and ascertain by impartial examination to what extent it satisfies by judiciously selected and accurate information the requirements of the medical and the pharmaceutical student. To the latter the "selection and collection of medicines" is a subject of great importance, and in the chapter with that heading such information as the following is to be found:—

"A decorticated tree affords wood doubly rich in medicinal principles, not only on account of its extra density but also because it is found that trees deprived of their barks whilst standing become more quickly the prey of insects; and as these do not remove the more active parts, weight for weight, such wood is more valuable than that procured in the ordinary way." (p. xxiv.)

Of barks it is said that

"when too old their extractive matters become impaired and their saline ingredients are exhausted by the rain percolating through their numerous fissures" (p. xxvii.).

"Extractive principle" is even now "ill-defined," but is said to be recognised by its

"amorphous condition and brownish colour, by its distinct but variable taste," etc. (p. xxxi.)

Again, we are told that

"cellulose, or cellular matter, is an organised substance... occupying the cell walls of plants," and that "ligin is used externally in the form of cotton and lint" (pp. xxxii. and xxxiii.).

These statements, and many of like character, which are to be found word for word in the edition of 1871, speak for themselves. Twenty-four years have not sufficed for their correction! The circumstance that the present editors are probably not responsible for this part of the volume cannot

remove the fact that such statements are embodied in a work offered to students.

The second part of the volume deals with inorganic materia medica. Here, speaking generally, the preparations and characters are taken bodily from the present or the previous edition of the Pharmacopoeia; the tests, which were included in Dr. Scoresby Jackson's original work, but were omitted by Dr. Moinet from the fourth edition, are still regarded as unnecessary, and only a stray one finds its way into the text. Yet these are becoming more and more essential. Neither pharmacists nor physicians manufacture the chemicals they use; these are purchased from men who have made their manufacture a speciality, and the pharmacist at least finds himself compelled to extend his knowledge of the tests by which he can establish the identity and gauge the purity of such preparations.

The third part of the work, which deals with organic materia medica, is made satisfactory. The classification adopted is botanical—an arrangement that has received the approval of the late Professor Flückiger. Here, too, the pharmacopoeial descriptions have been introduced, and to these notes have been appended indicating drugs that the characters detailed would exclude. The plan that has been followed is sound, but the hand of the expert is missed. Under podophyllum, for instance, the researches of Podwyssotzki and of Küster, which resulted in the isolation of both active principle and colouring matter in a pure and homogeneous form, have been ignored. Burk's work on the species of Erythroxylon yielding coca leaves, and Beckurt's on the alkaloids of cusparia bark appear to have been passed over. The old nitric acid test for the latter is most misleading: in this, as in the two quassia woods the only certain means of distinction is to be found in the structure. In the smaller details of the work many erroneous or only partially correct statements are also discernible.

For the medical student, on the other hand, the conditions are more favourable. Though he will doubtless find much that he will consider unnecessary, such portions of the work he can at least pass over. The pharmacology and therapeutics of the majority of drugs are accurate and well written; the style is as concise as it is lucid and attractive, and this part of the work will, without doubt, receive from the medical student the welcome it deserves.

It must, however, be admitted that the remarks previously made indicate the unsuitability of the work for pharmaceutical students and confirm the opinion that the endeavour to produce a materia medica that shall fulfil the requirements of both pharmaceutical and medical students is an attempt forcibly to unite two branches of a discipline, which year by year are becoming more and more divergent. The value of Dr. Scoresby Jackson's 'Note-Book' would be much enhanced by abandoning altogether in any future edition such an attempt, and by developing the pharmacology and therapeutics so as to render the work indispensable not only to the medical student but to the medical profession. The entire re-writing of Part I., the total excision of such articles as the loofah and vegetable marrow, of such drugs as Sium nudiflorum, S. latifolium, Imperatoria obstrahium, Eryngium aquaticum, and
BACTERIOLOGY IN ITS PRACTICAL ASPECTS.*
BY R. T. HEELEY, M.D. LOND.,
Demonstrator of Bacteriology in King's College, London.
(Concluded from page 820.)

As a further development of the bacteriological diagnosis of tuberculosis the inoculation method may be referred to. Cases occasionally arise in which a correct diagnosis may be of importance, but in which no tubercle bacilli can be found on microscopical examination, as in suspected tuberculous disease of the kidney. In such an instance, if a guinea-pig be inoculated in the thigh with some of the purulent deposit of the urine, infection with enlargement of the popliteal and inguinal glands will be evident in a fortnight if the case be tubercular.

By the inoculation method very definite information is obtained, and negative results are of almost as much value as positive ones, considering what a terrible scourge tuberculosis is, we ought to employ every available means to check its ravages. Unquestionably there is a risk, though perhaps a small one, of contagion from tubercular, especially phthisical cases, and the physician who neglects to warn a patient against disseminating his sputum has hardly done his duty. Tubercle bacilli have been met with in the air and dust of hospitals and rooms which have been occupied by tuberculous cases, and I therefore agree with those who desire to place tuberculosias among the notifiable diseases and who would disinfect rooms which have been occupied by consumptives. In New York this is done.

It does not seem to be generally known that in the smegma prepntif a bacillus is met in large numbers, which is very like the tubercle bacillus both in size and in staining reaction, and care should be taken to exclude it when examining urine for tubercle bacilli.

Actinomyces is a disease which often closely resembles tuberculosis, and it can be and can only be distinguished from it by microscopical examination. The recognition of actinomyces is of the greatest importance, for in some cases of the disease iodide of potassium acts as a specific. Although tuberculin as a remedial agent is not employed, it is regarded by the veterinary profession both here and abroad as a valuable aid in the diagnosis of early and doubtful cases of tuberculosis in cattle. For the diagnosis of the tuberculous disease in man, tuberculin is, I think, hardly a justifiable agent to use, on account of the disturbance it sometimes produces. Analogous to tuberculin is mallein, which stands in the same relation to glanders that tuberculin does to tuberculosis.

Mallein is prepared from pure cultivations of the glanders bacillus. The organism is grown in broth for about six weeks; the cultivation is then filtered through porous porcelain (a C. tamberland filter, for instance), and the germ free filtrate put by in tubes and bottles and then carefully sterilized. If about 1 Cc. of mallein be injected into a healthy animal, nothing, or only a slight febrile reaction occurs, in the horse not exceeding about 102°, the normal being about 100°; but if glandered ever so little the temperature runs up to 106° or even 106°. At the rest of inoculation a large swelling appears, and any local lesions if present become much enlarged. Both in England and on the Continent the results obtained with mallein have been most successful; as a diagnostic agent it is practically infallible; it seems, however, to act but feebly as a curative agent, although a few cases of apparent cure after its use have been reported. Anthrax again is a disease which can be diagnosed with certainty by microscopical examination of the blood or spleen, or of the local lesion, the malignant pusule. To the practiced eye, the anthrax bacillus is extremely characteristic, the shortish, non-motile, spore-less rods, which on staining are seen to be composed of 3-6 segments, can hardly be mistaken for anything else. At the same time the bacillus of malignant cedema, or the large septate bacillus which may make their appearance some hours after death, may be confused with anthrax by unskilled observers, and as a consequence some strange statements have been made from time to time.

Asiatic cholera is another disease in the diagnosis of which bacteriological examination is undoubtedly of great service. The Koch's combs bacillus is now universally recognised as bearing some relation to cholera, and it is the presence or absence of this organism which we rely on for diagnosis. In half the cases of cholera Koch's combs bacillus can be found on micro-examination of the rice-like flakes in the stools.

During an epidemic it would be impossible without a large staff to make the necessary bacteriological examinations in every case of diarrhoea; it would be wiser, perhaps, to treat every case of diarrhoea as cholera. The bacteriological diagnosis is of importance in distinguishing suspicious cases of diarrhoea which may occur at a time when infection is possible and an epidemic expected.

Diphtheria, too, is a disease in which the bacteriological diagnosis is coming to the fore. In New York this box of apparatus can be obtained at a large number of stations; on opening it you will see that it contains two tubes; one of these holds a small sterilised swab, the other is a tube of sterile blood serum. If you have a suspected case of diphtheria, you must rub the swab on the patch and then rub the inoculated swab over the surface of the blood serum. The tube is then placed in an incubator at 37° C., and in twelve hours, if the case be one of diphtheria, there will be numerous whitish colonies on the surface of the serum, and by microscopical examination the bacillus diphtheriae can be identified.

Then there is gonorrhoea; a microscopical examination of a doubtful urethral discharge may settle the

* Read before the Harveian Society of London, November 1, 1894.
question whether this be gonorrhoeal or no. A little of the pus is smeared on a cover glass, dried, fixed by passing through the flame, and stained for ten minutes with Löffler's methylene blue, washed, dried, and mounted in Canada balsam, and examined with a 1/12" oil immersion. The gonococcus is very characteristic; it is a small coccoid form generally in twos, and grouped fifteen or twenty together in the pus cells. Gonorrhoea appears to be a specific affection dependent upon the gonococcus, and some German authors, Nelser to wit, go so far as to say that a urethral discharge is not infective unless the gonococcus be present in it, a proposition which will hardly, I think, be accepted by English observers.

Bacteriological examination and analysis of drinking water, if carried out with certain precautions, affords valuable indications, especially with regard to the efficiency of filtration and of filter beds. Considerable discussion has taken place as to whether sewer gas is really capable of producing disease. Most authorities are agreed, I think, that it is dangerous, and Sir George Johnstone gives a long list of diseases which may occasionally arise through sewer gas poisoning—pleuro-pneumonia (homins), diphtheria, enteric fever, albuminuria, diarrhoea, cholera, erysipelas, puerperal fever, etc.

To my mind there seems to be every probability that disease germs do find their way into sewer gas, but granting, for the sake of argument, that this is not the case, some experiments by Alessi point to danger in another direction. This observer placed a number of rats, rabbits, and guinea-pigs in cages with perforated bottoms communicating with a drain. After exposure to the sewer gas they were inoculated with a small quantity of a slightly virulent culture of the typhoid bacillus. Of forty-nine rats inoculated, after exposure thirty-seven died, while of forty-one control animals similarly inoculated, but kept under ordinary conditions, only three succumbed. Of seventy-two guinea-pigs inoculated after exposure to the foul air fifty-seven died, of the control animals not one. Every one of eleven rabbits similarly treated died, but not one of the control animals.

It was further noted that the animals were most susceptible to the typhoid infection during the first fortnight of exposure, the mortality being 90 per cent.; in the third week this fell to 70 per cent. These experiments seem to be very suggestive, and point to the conclusion that sewer gas may render the animal body highly susceptible to various disease conditions.

In conclusion, I would express the opinion that the practical applications of bacteriology, numerous as they are now, bid fair to be much extended in the future, and it is a matter for surprise, if not regret, that not even an elementary course of bacteriological training has been included in the five years' curriculum.—Medical Press.

AN UNUSUAL SOURCE OF LEAD-POISONING.

BY FRANCIS J. H. COUTTS, M.B., CH.B. (VICT.), F.G.S.,
Late Resident Medical Officer, Victoria Hospital, Burnley.

During my term of residence in the Manchester Royal Infirmary as house physician, a man (F. N.), twenty-seven years of age, was brought to the accident room one day, as a case of acute intestinal obstruction, for immediate operation. As no very urgent symptoms were apparent, he was admitted to the medical wards, under Dr. Steell, to be under observation. The following morning the discovery of a very well-marked blue line on the gums cleared up the case, the diagnosis being lead-poisoning, with colic and constipation. The patient was pale, anemic, and rather nervous in manner; he complained of severe pain in the abdomen, chiefly referred to the umbilical region, relieved somewhat on pressure. There was a history of constipation for some days, but the bowels were moved on the day following admission.

The patient rapidly improved under the administration of potassium iodide; colic and constipation disappeared, and he left the Infirmary in nine days, feeling perfectly well. There were no signs of neuritis, except occasional feeling of pins and needles in the feet, and numbness and coldness of the hands on washing in cold water. Knee jerks and plantar reflex, wrist jerks, and trocochs reaction were all readily obtained.

At first, no clue could be perceived as to the source of the lead in this case. The patient stated that he was a worker in a rubber factory, and questioning ultimately brought out the fact that he had been for some time in the habit of chewing portions of the soft unfinished rubber. He believed white lead and red lead were used in the process of manufacture of the rubber, but had not to handle these himself. He was asked to bring a specimen of the material he had been in the habit of chewing, and it turned out to be in the form of thin sheets of brownish-red rubber, about 1/16 inch thick.

On incinerating the rubber, much residue remained which, dissolved in nitric acid, gave very abundantly the characteristic reactions for lead. When opportunity offered, I made a more systematic examination, with the following results:—The specific gravity of the rubber was 1.65, whilst, according to "Thorpe's Dictionary of Applied Chemistry," the specific gravity of pure caoutchouc is 0.925. A piece of the rubber, 1 inch long and 1/2 inch wide, weighed about 13 grains, and on ignition and incineration left 51.55 per cent. of residue, consisting chiefly of sulphate and carbonate of lead, with iron, etc. Quantitative analysis revealed the presence of 23.57 per cent. of lead, calculated as metallic lead (Pb), which would correspond to 29.44 per cent. of white lead, calculated as 2PbO4+PbH2O2, or 27.62 per cent. red lead, calculated as PbO2. This comparatively enormous quantity of lead would easily account for the symptoms of poisoning following the chewing of the rubber material. The patient was seen about twelve months after he left the Infirmary, and was then enjoying good health, but he still complained of weakness and cramps in his fingers after they had been in cold water. I have to thank Dr. Steell for kind permission to report this case, which may be of some interest as pointing out a possible source of lead-poisoning which I believe has not been hitherto suspected.—Medical Chronicle.
The Pharmaceutical Journal

FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, APRIL 13, 1895.

EDITORIAL.

Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

Advertisements Department.

Advertisements and remittances must be sent to "Street Brothers," 5, Berle Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased, and to whom Cheques and money orders should be made payable.

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary—Mr. Richard Brambridge, 17, Bloomsbury Square, London, W.C.

SCIENCE AND COOKERY.

The world is at the mercy of its cooks, and has been so since the beginning of what Dr. Thudichum describes as the "long process of experimental empiricism, at which all mankind has laboured from the early days of its existence." Though few people care to be experimented upon, yet most voluntarily offer themselves for the purpose at more or less regular intervals during each day. The result to the victims is sometimes satisfactory, more often simply unobjectionable, but not uncommonly decidedly provoking. How could it be expected to be otherwise when one reflects that the knowledge acquired by cooks during countless ages yet exists for the most part in the form of unconnected recipes, and that these, even when collected and published in portly tomes, still preserve their distinguishing character of incoherence? A systematic attempt to express this acquired knowledge in the shape of general rules, described by the author as being such as would result from a codification of principles, is now presented to long-suffering humanity in The Spirit of Cookery (Baillère, Tindall and Cox). The task Dr. Thudichum has set himself therein is "to produce such a system of general rules as will enable those who thoroughly master them to perform the principal culinary operations without reference to the frequently unintelligible records of the details of mere empiricism. These rules are based, in the first place, upon unimpeachable scientific data or fundamental truths which admit of no circumvention or compromise, but have to be obeyed under pain of certain failure."

This, then, is most decidedly no mere book of recipes, and, in truth, definite recipes are but sparsely scattered throughout the volume. What has actually been produced, however, is a readable yet thoroughly scientific treatise on the history, theory, practice, and ethical and medical import of the culinary art. At the beginning of the work a brief discourse on the evolution of cookery and its adaptation to various conditions paves the way to the statement of the hypothesis—that the state of culture of every nation can be estimated comparatively by its confectionery. The chapter concludes with a denunciation of the so-called economical practices indulged in by persons who are imbued with the delusive idea that good food can be prepared from "scraps costing nothing." A comprehensive sketch of the historic literature of cookery follows next in order, preceding chapters on kitchen requisites and culinary axioms, and general consideration of culinary processes. In these the hand of the chemist and physiologist are clearly indicated. Next, condiments and spices are grouped under the headings of saline, pungent, and aromatic substances respectively, parts of cruciferous and composite plants with sharp oil; aromatic herbs; and condiments; odoriferous parts of plants (not aromatic); colouring matters; and varieties and preparations of sugar. The author then plunges bodily into his subject, and the mere enumeration of the subject-matter of his subsequent chapters, whilst of general and all-surpassing interest, would more than occupy the space allowed to describe the book in its entirety. Suffice it to say that everything receives proper attention—soups of every imaginable description; sauces and their philosophy; jellies, vegetables, salads, cakes, and puddings; joints, game, fowl, and fish; ices, jams, custards, and cheeses; whilst the beverages discussed range from water, wine, beer, and spirits, to tea, coffee, chocolate, and tisanes.

In the concluding chapters—dealing with the cookery and meals of former generations, the philosophy of dinners and of dining, and the cookery of soldiers in the field—Dr. Thudichum displays a pleasing intimacy with that of which he writes, and it cannot be denied that he well fulfils the requirements he stipulates as necessary for authorship on the subject. These are a practical acquaintance with culinary processes, a good knowledge of physics and chemistry, intimacy with the historical literature of cookery of all times, a living knowledge—gained amongst the people of many lands—of all peculiar food-preparations, and the power of epitomising—after deep and very critical study—the works of previous authors. It is further significantly pointed out that the best treatises on cookery have been written by physicians. The writer of such a work certainly knows how to dine, and, knowing that, can furnish a satisfactory response to the question that will be first and last so long as mankind retains its capacity to think—"Is life worth living?" Those who would know the answer must needs refer to
the book itself, and consider the experience gained such as would be well earned at any cost. It is no exaggeration to say that, by the aid of Dr. Trudgill's book any person of average culture should be able to influence and direct his or her cook to the extent that all food prepared shall possess the necessary degree of refinement and digestibility. In conclusion, one cannot do better than quote what the author has to say respecting this refinement of food. After remarking that there are cynical persons who profess to despise the liking for good food (Fr., friends), he proceeds as follows:—"The refinement of food is not only the efflux of culture, but also has an important influence upon the mind, and consequently upon the abilities and manners of man. 'Tell me what you eat, and I will tell you what you are,' is a paraphrase of a saying concerning the influence of company, and is equally true. Many persons mistake a natural, desirable daintiness for gluttony, gloutonnerie—as Montaigne once termed it, 'La science de la gueule,' or 'The science of the gullet.' We hold absolutely with the 'gourmandise des esprits delicats'; if it cannot be satisfied, vitality is diminished, and life is shortened.'"

THE DANGERS OF COMPRESSED GASES.

The result of the inquiry into the cause of the death of William Holbook, who was killed at Fenchurch Street Station by the bursting of a gas cylinder on March 15 (ante, p. 821), can only be described as vague and unsatisfactory. Evidence was given by Messrs. Clarkison, who had filled the cylinder, to show that it was properly made, tested, and filled, and it was stated that great care was always taken to ascertain with what gas a cylinder had previously been filled before it was re-charged. For the purpose of displacement the same hydraulic pump was used for all gases, but it was urged that this was quite consistent with perfect security. Separate pumps were used for filling the cylinders with oxygen and hydrogen. Dr. Upham, chemical adviser to the Home Office, said that he had found the oxygen gas supplied by Messrs. Clarkison of perfectly satisfactory quality, and there was no reason to suppose that grease was used at their premises to assist in removing the valve tape. He had reluctantly come to the conclusion, however, that the cylinder had contained an explosive gaseous mixture which had been fired by some portions of finely divided iron or grease igniting. The mixing of the gases was probably caused by the hydraulic pump. Dr. Upham also stated that the Home Secretary intended to take up the question of the conveyance of cylinders of compressed gas by rail, and said he had no doubt new legislation would shortly be introduced to deal with the subject. He was distinctly of opinion that there is no danger in cylinders of compressed gas, when the steel is good and the gas unmixed and pure. Finally, the jury returned a verdict of accidental death, and recommended in a rider that all compressed gases of an explosive nature should be scheduled under the Explosives Act. Other recommendations were that all cylinders should be tested by the Government periodically; that they should not be allowed to be used or conveyed about unless bearing the Government stamp; that all manufacturers should be licensed by the Board of Trade; and that separate hydraulic pumps should be used in filling the cylinders. Moreover, it was suggested that a Railway and Board of Trade inquiry should be instituted. Since all the recommendations of practical value in the jury's rider, with regard to testing, filling, etc., appear according to Messrs. Clarkison's account to have been anticipated, we can only repeat that the result is most inconclusive, and further inquiry into the cause and means of prevention of such accidents certainly appears to be called for. A practical suggestion mentioned in the Daily News is that every such cylinder should have a valve that could be opened automatically when the pressure reached a certain fixed point, which should be less than half the resisting power of the cylinder itself.

A POINT IN TRADE ETIQUETTE.

A curious case under the Sale of Food and Drugs Act was briefly reported in last week's Journal (p. 882), and this week we are enabled to publish the magistrate's decision (see p. 906). Diluted acetic acid was asked for, and the purchaser was supplied with acid of the strength of 11.7 per cent., whereas acetic acidum dilutum, B.P., should not contain more than 4.27 per cent. of real acetic acid. Mr. Horace Smith, in announcing his decision, remarked that there was no suggestion of fraud or gross carelessness, and, "as far as he could see, it would be well if tradesmen were to emulate the defendant's conduct, and give their customers, if possible, a better article than was demanded or paid for." Assuming that the magistrate is correctly reported, it may well be thought that he is unable to see very far, for if a chemist—as the defendant is described, though his name does not appear on the Register of Chemists and Druggists, with the address given—supplies an article of greater strength than a customer asks for, it is difficult to comprehend why he should be eulogised as a public benefactor. Whether or not there was any suggestion made to that effect, carelessness was unmistakably displayed, and that, equally from the medical, pharmaceutical, and public points of view, of the grossest type. A pharmacist would be much less culpable in supplying drugs and chemicals below the official standard than above it, but he is careless or dishonest in either case, since no practical difficulty need be experienced in supplying exactly what is ordered.

INTERNATIONAL EXHIBITION OF PRESERVED FOOD-STUFFS.

An international exhibition of preserved food-stuffs will be held at Brussels, commencing May 6 next, when the proceedings will be inaugurated in the large hall of the Marché de la Madeleine, under the honorary presidency of the burgomaster, M. Bults. Full particulars of the regulations, prices, etc., will be sent by M. Léon Philippart, 9, rue Jules van Praet, Brussels.
Transactions of the Pharmaceutical Society of Great Britain.

FIRST EXAMINATION QUESTIONS.
April 9, 1896.

LATIN.
(Time allowed—11 a.m. to 12.30 p.m.)
I. For all candidates. Translate into Latin:—
1. The judge's daughters are very miserable.
2. We shall set out from Carthage.
3. Had your sisters been ordered to praise that boy?
4. He asked whether this was true or not.
5. Three hundred of us are prepared to conquer or die.

II. Translate into English either A (Caesar) or B (Virgil).
(Candidates must not attempt both authors.)

A. CAESAR.
1. Diviso respondit: 'Ita Helvetios a majoribus suis institutis esse, uti obelides scedipere, non dare, conscerint; ejus rei Populum Romanum esse testem. Hoc respondere dato, discereas. Postero die castra ex eo loco movent: idem facit Caesar; equitatumque omnem, ad numerum quattuor milium, quem ex omni Provincia et Aedulis atque eorum sociis cometam habebat, praemiit, qui videat, quas in partibus hostes iter faciant.

2. Dum ea conquiruntur et conferuntur, nocte intermissa, circiter hominum milia sex ejus pagi, qui Verbigenus appellatur, sive timore perterriti, ne, armis traditis, supplicio afficendos, sive ase salutis inducti, quod, in tanta multitudine deditiorior, suas fugam aut occulti, aut omnium ignorari posse; xistatorem, prima nocte ex castris Helvetiorum egressum, ad Rhenum finesque Germanorum contenduntur.

Grammatical Questions.
(For those only who take Caesar.)
1. Decline, in the plural, ejus pagi; and, in the singular, sanitatem (Passage 2).
2. Give the third person singular of the indicative perfect, and the third person plural of the subjunctive present, of all the verbs in Passage 1.
3. Account for the case of testem, respondio, loco, militum, corum, partes (Passage 1).
4. Write, in oratio recta:—“Ita Helvetios . . . esse testem” (Passage 1).

B. VIRGIL.
1. Acrobas haec contra: Tuns, o regina, quid optes, Explorare locum; mibi fases, capessare fas est. Tu mihi quodcumque hoc regni, tu seopta lovenque Concillia, tu des epulis accumbere divum, Nimborumque facies tempestatiamo potentem. Haec ubi dicta, casum conversa capside montem Impulit in latus; ac venti velut aegmine facto, Qua data porta, ruent et terras turbine infrint.

2. Obstituit simul ipsae, simul percurruss Aechates Laestiaque meteque; avidi comulgare dextrae Ardebat, sed res animo incognita turbae. Dissimulant et nube cava spectantium amicti, Quae fortuna visris, classam quo littera linquant, Quid veniant; cunctis nam lecti navibus ibant Orantes veniam, et templum clamore potebant.

Grammatical Questions.
(For those only who take Virgil.)
1. Decline, in the singular, res incognita; and in the plural, cunctis navibus (Passage 2).
2. Give the third person singular of the indicative perfect, and the third person plural of the subjunctive present, of all the verbs in Passage 1.
3. Account for the case of haec, regina, mibi, cupide, latus, aegmine (Passage 1).
4. Mention two prepositions which govern both the accusative and the ablative, and give sentences in illustration.

ARITHMETIC.
(Time allowed—12.30 p.m. to 2 p.m.)
[The working of these questions, as well as the answers, must be written out in full.]
1. If 81 gallons fill a cistern 4 ft. 4 in. by 2 ft. 8 in. by 1 ft. 14 in., find the number of cubic inches in a pint.
2. If £32 8s. is paid for rent from July 10 to November 22, what should be paid from September 3 to October 28?
3. Simplify: \(0 \frac{15 \times 2.1}{34} - 04\).
4. What is the value of £9727 of £2 10s. ?
5. Into how many pills of 325 milligrams each can a mass of 28.4 grammes be made?
6. A man spends 65 per cent. of his income, and saves £434. What is the amount of his income?
7. The difference between the incomes derived from investing a certain sum in 6 per cent. stock at 126 and in 9 per cent. stock at 210 is £22 10s. What is the amount invested?

ENGLISH.
(Time allowed—3 p.m. to 4.30 p.m.)
1. Analyse:—
"The hand that for my father fought, I honour as his daughter ought."
2. Parse fully:—that, for, honour, as, ought.
3. Write short sentences, using the following words first as adverbs, and secondly as prepositions:—in, down.
4. In the following passage supply the necessary capital letters, and put in the stops and inverted commas where necessary:—capital I said as I entered now was seymour i want to borrow this boy for an hour why she asked because his grandfather is waiting to see him at his house oh then i am coming too she said at once my father shant have curf without me i am resolved.
5. Give a short biography of some distinguished soldier of statesman of the present century, or an outline of the reign of one of the Tudor sovereigns. (This must be attempted by every candidate.)

EVENING MEETING IN EDINBURGH.
Friday, March 22, 1885.
MR. J. LAIDLAW Ewing in the chair.
(Concluded from page 572.)

Waters.
By W. S. Glass.

There are sixteen waters in the B.P. Thirteen, including Aq. Dest., are prepared by distillation, two—camphor and chloroform—by solution in distilled water, and one, "Aqua" natural water, purest obtainable.

Aqua Distillata.—Under "Tests" for Aqua Dest, as for all other substances should be stated the impurity tested for. This would encourage the more frequent use of tests for purity, and would make the Pharmacopoeia a more intelligible book to juniors and apprentices. The new pharmacopoeia ought also to contain a table of solubilities in water and other solvents—as spirit, glycerin, olive oil—of the more generally employed salts, oils, gases, &c., at ordinary temperature. This would serve as a ready reckoner no less to the physician than to the pharmacist.

The B.P. methods of preparing the waters are defective in the case of snipe, dill, caraway, fennel, and pimento. 1. By not providing for previous maceration of the bruised dried fruits; 2. By not ordering distilled water; and 3. By excess of material for a saturated solution of the oil. Though "Aqua" of the B.P. may contain no visible impurities, still many invisible organic impurities may be there and will pass over in the first stage of the process of distilling these waters, and thus the distillate will contain such impurities. There is also no instruction given for preserving the aromatic waters, which should be stored in stoppered bottles, kept quite full.

Except in two cases, orange flower and cherry laurel, no characters and tests are given, and no doses prescribed except in camphor and chloroform. The B.P. methods should be abandoned and a more uniform process adopted. Tests and doses should be given and distilled water employed.

In some pharmacopoeias the term Aqua has a somewhat wide application, and embraces solutions of ammonia and other like substances (see U.S.P.). The B.P., with one or two exceptions, chloroform and camphor, adheres to the definition of water as an aqueous saturated solution of essential oil. Camphor, although a steropen, is a natural product, is soluble in water, and resembles in its properties the essential oils. This leads us to ask how the pharmacist may best obtain a saturated solution to be equal, if not superior, to that obtained by the process of distillation, a process the pharmacist for want of space and on account of expense cannot adopt. It would not pay. Many methods have been proposed.

The U.S.P. method of dividing the oil by means of precipitated phosphate of calcium is not free from objection, for no substance is entirely insoluble in water. Other substances, as tate, silico, kaolin, magnesia, and chalk, are all objectionable for the same reason, and quite unnecessary besides. Percolation through cotton or pulp moistened with the oil is not always satisfactory, and alcohol is objectionable, as shown by Warrington in 1845, and other experimenters since, acetic acid being formed. The use of concentrated waters, which all contain alcohol is to be condemned.

Aqua Chloroformi is not a water, and ought to be removed. It should be placed among the liquors. It is not a solution of an essential oil, although largely employed as a vehicle for unpalatable medicines. Aqua Laurocerasi should be omitted because it is a dangerous water, on account of: 1. Its uncertain strength. 2. Its liability to chemical decomposition. 3. Its tendency to lose hydrocyanic acid and so become inert.

It is not desirable to multiply unnecessarily the B.P. preparations. The introduction of aqua caryophylli to displace aqua pimento would be an advantage. It is difficult to distinguish waters made from ol. pimente and ol. carophyl. Ol. carophyl is always at hand, whereas ol. pimente is never sold and is much dearer. Aqua caryophylli might also take the place of infra. caryophylli, which is little else than a solution of the essential oil in boiling water.

The best method.—The distilled waters of the B.P., as officially prepared, frequently possess a rank, unpleasant odour, and do not keep well. Especially is this the case with sambuci, rosae, and aurantii florae, which produce on keeping fungoid growths. As some waters have to be kept for a length of time in the pharmacy before they are required, a demand has been created for concentrated waters which are said to keep better, and it is matter of common knowledge that these are employed in many instances just as concentrated infusions and decoctions are kept and used for the fresh article. Many chemists, no doubt, prepare the aromatic waters by simply shaking the essential oil with water, and these sometimes compare favourably with the official product. Waters are so frequently wanted that a method at once simple and satisfactory ought to be introduced into the new pharmacopoeia. Various so-called simple methods appear from time to time in the journals, but the details and intricacies of most of these place them at once outside the region of practical pharmacy. The solution of essential oils in cold water is good, and in some cases, as in cloves and cinnamon, a fair water is obtained. I find that waters prepared with spirit have in most cases a harsh and sometimes, as with peppermint, caraway, dill, and cloves, a decidedly bitter taste. The best method is maceration in hot water with occasional agitation, and filtration when cold through a double fold of white well wetted filtering paper. I have prepared all the B.P. waters except cherry laurel and elder flower by this method, and compared the products with those obtained by maceration in cold water only,
also with cold water and spirit (known as the essence method), and also with those obtained by distillation, and I find that the hot water gives an article which is superior for full flavour and strength to that obtained by any of the other methods. I have for a year or two adopted the hot water process with peppermint, cinnamon, dill, and caraway, and the results have always been satisfactory. These waters possessed the full flavour and strength of the oil and kept well. A saturated solution is obtained, and any other method can give no more. The origin of the hot water process dates as far back as 1874 (see American Journal of Pharmacy), and has been advocated since then by Remington and Proctor. It commends itself for its simplicity, uniformity—all the waters being capable of preparation by this method—cheapness, and good results. Water at from 60° to 65° C. gives the best results. The finished product is clear and bright, and does not become turbid on keeping.

The strengths of all the waters ought to be uniform, 1 in 500, as in U.S.P. Notwithstanding the variation in solubility, this strength insures a saturated preparation.

The three waters which are prepared by distilling the flowers are generally imported. The keeping properties are a serious objection to these. They soon become turbid, and numerous fungoid growths are frequently produced in them, and ultimately the fragrant odour gives place to a decidedly offensive one. Aq. aurantiil floris is readily prepared from col. neroil, aqua rosea from the otto, and aqua sambuci from the essential oil. Thus prepared these waters have a finer aroma, keep well, and have the additional advantage of being prepared at once when wanted. These three waters should be termed "triple," and a dilute form of 1 to 2 of distilled water added. These latter are largely used for toilet purposes, and the dilute form would also be quite suitable as a flavouring agent in mixtures, etc.

The clumsy method of preparing aqua camphor should give way to a more rational process. Powdered camphor readily gives a saturated solution when hot water is employed.

The doses.—I do not think serious objections can be offered to uniformity in this matter. Half to two ounces is a suitable standard, and would apply to all except the three triple waters, older, orange flower, and rose.

Characters and tests.—There is no reason why a general method of preparation should not be given once for all with the general characters, tests, and doses. The waters should all be clear and bright, possessing the odour of the oils from which they are prepared.

The tendency nowadays is toward simplicity and uniformity. The chemist, the student, and the physician call loudly for simplicity in method and uniformity in dose as in strength; and one method, one strength, and one dose for all the waters of the Pharmacopoeia would be a step in the right direction.

LINSEED MEAL.

BY ALEXANDER J. DEY.

There is evidently a very unanimous opinion that the cataplasmata should be excluded from the Pharmacopoeia. That being so, it may be said that linseed meal should disappear also, but this does not follow. There can be no doubt that, so long as it is regarded as the most efficient material for that purpose, it will be prescribed by medical men for the making of poultices. For that reason there ought to be a definite standard of quality fixed in the new edition of the Pharmacopoeia. What follows will show that there is great need for some means of securing uniformity, and so guiding the dispenser as to meet the requirements of the prescriber and the ordinary demands of the public. At present the Pharmacopoeia gives no standard or test of any kind. It simply states that linseed meal should be "linseed reduced to powder," the state of division and the quality being left to the discretion of the chemist or grocer by whom it is sold. That there is a wide difference, even in appearance, may be easily seen from an examination of the nineteen samples placed on the table, ten of them having been purchased from grocers and eight from chemists. The grocers' samples especially show a decidedly inferior quality of meal; five are very dark in colour, and have the appearance of having been prepared from the ground oil-cake, to which a certain proportion of linseed oil has been added; four have been only very roughly crushed, and are similar to what is generally sold for feeding cattle; the remaining one is a sample of the powdered oil-cake formerly official in the 1867 Pharmacopoeia. The chemists' samples are all, with one exception, of good quality as regards the percentage of oil. In appearance they vary in colour from a bright yellow to a dirty brown. With one exception the state of division corresponds to No. 20 powder, the exception being similar to some of the grocers' samples resembling cattle-feeding meal.

From the foregoing it is clear a necessity exists for inserting some definition and standard of purity in the Pharmacopoeia. With a view to determine what tests might be suggested to secure uniformity, I examined the eight samples purchased from chemists for percentage of oil, freedom from cruciferous seeds, absence of starch, and percentage of ash. The results are as follows:

<table>

No. 9 was powdered by myself from good seeds, and consists of the powdered seeds, with about 20 per
cent. of the testa or husk removed. Exclusive of No. 9 the samples show average percentage of oil 35-3, and of ash 3-35. The sand was got by treating the ash with hydrochloric acid. It consisted of distinct fragments of silica, evidently present among the seeds as an impurity. None of the samples gave any evidence of cruciferous seeds or starch. Nos. 4, 6, and 7 gave a markedly acid reaction with moistened litmus paper, indicating that the oil contained in them was considerably oxidised. Nos. 2, 5, and 7 are of a bright yellow colour. They seem to be artificially coloured, as, if a few grains are placed on white bibulous paper and saturated with chloroform, they impart a distinct yellow stain to the paper. The test sample No. 9, when similarly treated, gave no colour. The nature of the colouring matter has not yet been determined. It looks very like turmeric, but the presence of powdered turmeric would be detected by the starch test. The ash was colourless.

The U.S.P. requires that ground linseed or linseed meal should yield not less than 25 per cent. of oil, and should not be coloured blue by iodine test solution (absence of starch). The Belgian, French, and Italian pharmacopoeias require it to contain 30 per cent. of oil. I would suggest that in the new pharmacopoeia linseed meal should be defined as "linseed reduced to No. 20 powder," and should have appended to it the following:

Characters and Tests.—A dark yellowish-grey powder; should be recently prepared and free from unpleasant or rancid odour. A decoction when cold does not become blue on the addition of solution of iodine (absence of starch); the meal does not give off a pungent odour when treated with warm water (absence of cruciferous seeds); when exhausted with carbon bisulphide should yield not less than 30 per cent. of oil; and when incinerated should yield not more than 6 per cent. of ash.

In the U.S. Dispensatory (page 788) it is stated that the percentage of ash should be less than 5 per cent. But this is too high, and in view of the foregoing determinations 5 per cent. gives ample allowance. I have to thank Mr. W. B. Cowie for kindly making the ash determinations.

Dr. Tillie said he agreed very fully with the remarks made with reference to aconitine, veratrine, and atropine ointments. He had an especial objection to carbolic acid ointment, more especially as carbolic acid acted as a local anaesthetic, and hence sometimes caused considerable destruction of the tissues. Mr. Boa did not specially refer to the mercurial ointments. He thought two of these ought to be removed—ammoniated mercury ointment, which usually underwent decomposition, and mercurial ointments, made with un. cetace—as they often were liable to change colour. It was quite common for them to order for inflammation of the eye as a mercurial ointment yellow oxide of mercury. It would be much better to use paraffin as a basis if it were possible to get a perfectly bland preparation. With regard to the infusions, this was a point on which there was a little feeling. It was quite common for a physician to write a prescription "infusion so and so"; it was equally common for a patient not to get it, interferences having taken place with the pharmacopoeial instructions, the chemist and druggist having quite illegally and without any pharmacopoeial authority dispensed something containing alcohol which ought not to be in the infusion as prescribed. Of course, one might put it down as a trade practice, which covered a multitude of sins. He thought it would be very proper to introduce "Infusion so and so recens" and "Infusion so and so concentratum," or something of that sort, to get over this little difficulty. But it was highly improper to dispense A for B, and the earliest possible step should be taken to put chemists and druggists on a legal footing in the dispensing of these preparations.

They should not dispense rectified spirit, a preparation which was not asked for, when there was no authority for doing so. He thought it would be a very excellent thing to have both fresh and concentrated infusions in the Pharmacopoeia. He thought it was an advantage that infusions often rapidly underwent decomposition, because if there was any form of wickedness that patients were more addicted to than another it was in keeping bottles of medicine too long. When they thought they had got the same illness as they had last time they took the old bottle, without realising what had happened. The charm of the fresh infusion was that the mixture did not keep, and chemists and druggists often, by adding concentrated infusions which did keep, did themselves a great deal of harm, since the mixtures after being kept for a time could yet be taken, whereas if made with the fresh infusions they would go bad and have to be renewed. It ought to be clearly stated whether infusion of digitallis was to be made with the unbroken leaf or with the broken leaf, and the size of the broken leaf should be definitely stated. He did not know any preparations that one depended upon more than the infusion and tincture of digitalis, and there was nothing more important than making them with the most precise attention to details. He had a strong objection to the deletion of pil. saponis co. When one wanted to conceal from the patient that he was taking opium he knew no happier method than by prescribing pil. saponis co.

Dr. Sillar said it seemed to him that to a very large extent the Pharmacopoeia could be systematised. In one of the recent numbers of the British Medical Journal, a medical man, writing on the subject, remarked that it was very rare for medical men to have the Pharmacopoeia in their library. He thought there were one or two very intelligible reasons for that. The majority of the copies of the British Pharmacopoeia were used by the chemists and druggists. The Pharmacopoeia was excellently arranged if they wanted to prepare a single specimen of a drug, but it was not good for any other purpose, and it was owing to this that he thought it was not used by prescribers. If it were properly systematised, great use might be made of it. He meant by that that the substances should be grouped together. As Mr. Glass remarked with regard to the waters, the same thing ought to be carried out with every preparation. The Pharma-
copaedia ought to be a text-book, and every student ought to have it as a text-book from which he was to work. It had impressed itself very much on his mind that the reason why so few of the infusions of the Pharmacoopedia were prescribed was that as at present arranged no doctor or knew what infusions were in the Pharmacoopedia, because they were not arranged in any way in which he could learn them off by heart, and he got into a routine method of prescribing one or two infusions in certain cases. It also seemed to him that a great deal of attention was paid to the waste of the infusions. In that way it seemed to him that the chemist was very apt to work at cross purposes with the physician.

If the Pharmacoopedia were printed in tabular form, in a certain systematised way, medical men could look for certain pieces of information in certain places. And what they required to do was to impress on medical men generally to have a very much more profound knowledge of the Pharmacoopedia than they had. The greater the knowledge of the Pharmacoopedia the physician had the easier it would be for the chemist and druggist. The first essential was that the name of the substances should always be defined, and when they once used a term they should keep to it. All their aim in medicine as the days and years went on was to be more and more nearly accurate, and they would like to substitute active principles for galenical preparations. He did not see any reason why, where it was possible, the physician's instructions and the processes set down should not be scrupulously adhered to in every case, even where they found it not to be most advantageous.

He did not see why the physiological tests of preparations of belladonna should not be one means of standardising these; but where the chemical method could be carried out it was preferable. One of the speakers remarked that certain other preparations might beclassed under ointments. He would object to that because of the difficulty he found in teaching the subject, owing to the perplexity of giving a definition and there being an enormous number of exceptions. A great many remedies were being proposed to be struck out of the Pharmacoopedia, owing, as he thought, to ignorance of their properties in the medical profession. Canella bark was an extremely useful substance because of its pleasant odour and its strong taste in covering certain disagreeable substances one wished to administer in the form of powders; but owing to the Pharmacoopedia not being arranged in a definite form its properties were not so well known as they ought to be. Take also for example baal fruit, although it might not be largely prescribed in this country, from the north to the south of the great Indian Empire it was extensively employed as medicine for dysentery. If the Pharmacoopedia was to become an International Pharmacoopedia, and apply to Britain and the colonies, not only baal fruit but a large number of other substances must be added for use in the colonies. This might be done by transferring to an appendix what might be struck out of the body of the Pharmacoopedia. The solubilities in cold water should be more fully noted. It was owing to the want of knowledge of solubilities that such a large number of incompatible prescriptions were written.

Mr. Dott said, with reference to a recent statement by Dr. Lauder Brunton, that the Pharmacoopedia should contain a table of solubilities and give information as to incompatibilities, that could only be done on a very limited scale. He seemed to wish that all possible accidents or incompatibilities that could arise in the mixing of various substances should be indicated, but that would be extremely difficult, and no table that could be devised would do so. There was one other point referred to by Dr. Lauder Brunton. He wanted to know how much of a substance dissolved in hot water would remain in solution when the liquid became cold. The answer to that was that under normal circumstances the same quantity of substance remained in solution when the liquid cooled as would be dissolved by water at the ordinary temperature of the air. In only two circumstances would this rule be departed from. Either when a strong hot solution was cooled at rest and produced a supersaturated solution which would deposit crystals on agitation or standing, or when the substance had undergone chemical decomposition by heat. Under all ordinary circumstances a solution made by cooling a hot saturated solution would be of the same strength as a saturated solution prepared with cold water.

On the motion of the Chairman, votes of thanks were awarded to the authors of papers.

The Assistant-Secretary then directed attention to some recent additions to the Museum and Library and on the motion of the Chairman, a vote of thanks to the donors was unanimously passed.

The meeting then closed.

Proceedings of Societies in London.

ROYAL INSTITUTION OF GREAT BRITAIN.

Lord Rayleigh's lecture on "Argon," on the 5th inst., naturally proved a great attraction, and the lecture theatre was crowded half an hour before the commencement, the audience including Mr. A. J. Balfour, M.P., Sir Frederick Abel, Sir Henry Roscoe, M.P., Professors Dewar, Rücker, Ramsay, and Roberts-Austen.

The lecture resolved itself into a popularised version of the communication read before the Royal Society on January 31 (ante, p. 676), but several facts of additional interest were disclosed, and various methods for the preparation of argon experimentally described.

At the outset Lord Rayleigh referred to the lecture which he gave some four or five years ago on the densities of oxygen and hydrogen gases, and the conclusions drawn therefrom, and described the experiments which caused him to suspect the presence of another constituent in the atmosphere. In the first of these—a process intro-
duced by Professor Vernon Harcourt—air was bubbled through liquid ammonia, the relative weight of the nitrogen so obtained being noted. After concordant results had been obtained, nitrogen was prepared by the ordinary process in which air is passed over red hot copper, when copper oxide is formed, and it was noticed that the relative weight of the gas liberated was 1/1000 part more than the mean of that prepared by the first process. This was three years ago, and the discrepancy troubled him a good deal, various theories being advanced to explain it. The most useful suggestion was one made by Nature to the effect that, by the first process partial dissociation of the nitrogen from the ammonia had taken place.

If that were true the discrepancy was explained at once, but the theory was discredited—first, by storing a sample of chemically prepared nitrogen for several months, when no change occurred; and secondly, by the fact that the silent electric discharge had no sensible effect on nitrogen prepared by other process. Further, the difference between the relative weights of the two gases was confirmed by preparing "chemical" nitrogen by a variety of other processes, and by bubbling oxygen instead of air through the ammonia in Harcourt's process. Generally speaking, it was found that "chemical" nitrogen was ½ per cent. lighter than "atmospheric" nitrogen. At this stage in the research he asked himself, "What evidence have we that the nitrogen of the air is all of the same kind?" and on setting this question to Professor Dewar, was referred by him to Cavendish's work. Lord Rayleigh referred in detail to that chemist's researches on the composition of the air, and showed the Wimshurst's electrical machine which was employed for sparking mixtures of common air and dephlogisticated air (oxygen); at the same time pointing out how Cavendish to a great extent solved with his crude apparatus the question now raised after a lapse of more than a century. Indeed, he had himself used a modification of Cavendish's apparatus for the preparation of argon on the large scale. By this process, which he had adopted at Mr. Crookes' suggestion, alternating currents from the men of the Electric Supply Company—in connection with the Royal Institution—are passed through a Rohmkorf's coil, high potential transformers being used, and thence through bent glass tubes, filled with mercury and fitted with platinum points, into a large glass globe in which are the mixed gases. Arrangements are made by which absorption by strong caustic alkali takes place after sparkling, until the residue resists the prolonged action of the current; and the top of the globe is cooled by encircling it with a jacket of sheet lead through which a continuous current of cold water passes, thus forming an efficient condenser. It is essential that the platinum terminals should be very massive, so as to resist the enormous heat generated, and the collecting vessel must be made of glass. With this improved apparatus seven litres of the mixed gases can be absorbed per hour when present in about equal proportions, and passed in automatically. The other process for making large quantities of argon has been perfected by Professor Ramsay, and consists in passing "atmospheric" nitrogen over red hot magnesium turnings contained in a combustion tube, when magnesium nitride is formed, the residue from the "atmospheric" nitrogen consisting of argon. The apparatus is necessarily rather complicated, but by its means argon can be obtained much more rapidly than by sparking; however, Lord Rayleigh rather prefers the latter method, as it does not entail such constant attention as the first. The gas prepared by either process is an exceedingly inert body, and it is supposed that the two products are identical. It has been found impossible as yet to produce argon free from nitrogen. It always contains at least 1½ per cent. of nitrogen, which can readily be detected by the spectroscopic method.

Since the reading of the communication before the Royal Society, several attempts had been made to induce argon to combine. Thus, no compound had been formed when exposed to the action of titanium at a red heat, although an inert body like nitrogen does. But during the last few weeks Berthelot has stated that by the action of the silent electric discharge it can be absorbed by the vapour of benzene; and so recently as the last few days Lord Rayleigh's son and Professor Meloda had tried to form a compound by sparking argon and acetylene together, when it was noticed that the volume of gas increased, although when acetylene alone was sparked no increase was observed.

Determinations of the solubility of argon in water show it to be the same as oxygen, and about two and a half times as much as nitrogen. These are of special importance as affording indications of good sources of argon on a large scale, owing to the much greater solubility of argon in water than nitrogen. In fact Lord Rayleigh had recently received from Manchester argon which had been obtained from the condensing water of steam engines. Turning to the spectrum of argon, allusion was made to the indebtedness of the speaker to Mr. Crookes for his work on the subject, and tubes of rarefied argon were shown, which, when illuminated by an electric discharge, were red or blue according to the character of the current employed. Spectroscopic examination had also been utilized in an attempt to distinguish between argon prepared by the alternating current method and that by the magnesium method, although no difference had been detected. A radiometer that Mr. Crookes had charged with argon during the last few days was shown, and when placed in the electric beam revolved rapidly. The density of argon prepared by magnesium had been carefully determined and fixed at 1.99, whilst that obtained by sparking was approximately 1.97. One of the most important properties of argon was the ratio of its specific heat at constant pressure and constant volume which we found to be 1.65, and hence approaching to the theoretical limit of 1.67. It is hence concluded that it has no energy, with the exception of that of the translation of its molecules, for if it had any other energy it would drop below 1.64, or even lower still.

Upon the basis of the ratio of the specific heat of
Correspondence.

THE MAJOR EXAMINATION.

SIR,—I think the suggestion of "M.F.C.S." (that it be made possible to pass the subjects of the Major examination one by one, they being placed successively to the credit of the candidate) a very unwise one. I should indeed sorry to see so excellent and honourable an examination desintegrated and degraded into a paalty system of spasmodic and piece-meal cram. The subjects of the "Major" are so dependent one upon another, and all of them so closely related in their application to pharmacy, that their concurrent study is an absolute necessity; and to take the subjects singly, at indefinite intervals, would certainly not tend to that thorough and more professional pharmaceutical knowledge which is the object of the Major examination. But if the suggestion of "M.F.C.S." be so unhappy, how irrational is that of "Verbacum," which expects the Council of the Society to "make concessions," that is, to provide a "modified Major" for those who have remained associates during a certain length of time, "as a mark of appreciation of their support." Can he really think that the Council will barter the qualification of pharmaceutical chemist to encourage the "support" of its associates? I offer these remarks not in any carping spirit, but because I am convinced that on reconsideration "M.F.C.S." "Verbacum," and others, will determine to pass the Major as it now stands, and, if they be so determined, they will find that most of the obstacles they name will prove merely evanescent.

HERBERT DYSON.

THE REVISION OF THE BRITISH PHARMACOPOIA.

SIR,—Now so many able men are suggesting alterations in the coming B.P., I feel that such a humble member of the craft as myself ought to be silent; I nevertheless venture to propose that no galleonics be introduced into the B.P. that cannot be made in an ordinary well-equipped pharmacy, and that preparations be ignored that can only be made in a large factory; also that concentrated infusions be forbidden to be used in prescriptions, when infusions are ordered.

SOM REMO.

FRANK R. SQUIRE.

A CORRECTION.

SIR,—In your report of a discussion on a paper read to the Chemists' Assistants' Association, you say that I put in a word for the retention of the soap basis for some suppositories. This is hardly correct. What I did say was, that in view of the fact that this basis for suppositories is repeatedly prescribed by one of our most eminent surgeons, its deletion from the B.P. would not meet with the universal approval of the medical, though it did of the pharmaceutical profession.

RALPH MEILHUISS.

THE REMUNERATION OF DISPENSERS.

SIR,—While you are interesting yourself on behalf of poor law dispensers, allow me to call your attention to the case of the dispensers to the London County Council, whose maximum salary has lately been reduced to £120.

"VERITAS."*

* Perhaps "Veritas" will favour us with further particulars than appear in his present brief communication [Ed. Pharm. Journ.].

SIR,—Having read your article on "Poor Law Dispensers," I should like to offer a few remarks in reference to the status and remuneration. I think it hardly explains that there are two classes of poor law dispensers, namely, one under the Local Government Board, the other solely under the guardians. This is where the evil steps in. The poor law dispensers orders only refer to London dispensers (Metropolitan Dispensers Orders, 1871), but in your article you draw no distinction. I was partly under the impression that the orders applied to the provinces until a friend put himself in communication, through a local member of Parliament, with Sir Walter Foster, who confirms what I have said, that there are two appointments for qualified men. If it were not so, under Art. 13 of the Poor Law Board Orders all would have to be qualified or they would not be sanctioned by the Local Government Board. This is where, in my opinion, the Pharmaceutical Society ought to step in. I think it is of great importance for the public safety that a public body should be compelled to employ a qualified man to dispense, in some cases as many as 1000 bottles per week, for if an unqualified man is caught selling a pennyworth of Laudanum he has to pay the fine. If the Society urged the matter before the Local Government Board I think they would see the matter in a fair light, and they have the matter solely in their own hands. As regards the smaller unions not having sufficient work for a dispenser, I do not see why this should be an excuse for employing an unqualified man, but in most small unions the medical officers supply their own medicines, and it is allowed for in their salaries. As to the salary paid, I had not seen the report you mention fixing the commencing salary at £210, with a maximum of £240. In the Journal of August 18, 1894, a dispenser is adver-
tised for £80 a year with dinner and tea; on January 27, 1894, one at £90, increasing to £100. This shows that the guardians are not bound by a minimum salary, and as regards the maximum I may say my own agreement goes beyond the £140.

Sheffield.

HERBERT ANTCLIFFE.

Sir,—The thanks of all dispensers in the public services are due to you for your sympathetic leader on "Poor Law Dispensers" in the Journal of March 30. I am a poor law dispenser of some years' standing, and am connected with the efforts made by my fellow-dispensers to improve their position, which, for the information of others, it may be well to epitomise. Briefly, then, in the year 1886 a memorial was submitted to the Local Government Board, and in this attention was directed to the following points:—1st. That being specially qualified and responsible officials, we were aggrieved by the absence of any provision for increase of remuneration, except that granted after the first four years of service. 2nd. The detrimental effects both to the service and to ourselves from this cause, as after a certain time there is no inducement for dispensers to continue in their appointments. 3rd. That owing to the nature of our duties, no promotion, other than pecuniary, was applicable to us, and we was not possible while the present regulations were obtained. 4th. That the knowledge gained by long service is invaluable in economically conducting the dispensary, and would, at least, partially compensate for any increase of salary awarded. 5th. That a provision, similar to that we desired, already applied to most other responsible officials in the service, e.g., the relieving officers, whose salaries rise periodically until fifteen years' service is attained.

We submitted a scheme which insured the dispenser a maximum salary of £200 per annum after sixteen years of service. The Local Government Board's reply stated that "they were unable to consider that they would be justified, under present circumstances, in making any alteration in the scale of remuneration for dispensers settled by them in the year 1886"; this being the one £20 rise recommended and referred to in their report for the year 1876, and is the only increase of salary obtainable. The present system of service satisfies neither the dispenser nor his immediate employers the guardians, several boards having unsuccessfully requested the Local Government Board to consent to an increase of salary for their dispenser after long service. Should the Local Government Board after a lapse of nine years now consent to the suggested extended scale, or any portion of it, adequate and efficient safeguards against abuse are provided, viz.: 1st. The proposed increments are dependent upon length of service. 2nd. It must be satisfactory service, or the local board of guardians will not recommend the official for the increase of salary. 3rd. It would probably have the effect of weeding out any unsatisfactory men in the service. There were no doubt weighty reasons which operated against the adoption by the local Government Board of a more extended provision for dispensers in the year 1876; the most cogent being, perhaps, that the class had been only four years in official existence, and that it was inadvisable to render permanent, as a scale would do, a body of officials, who, should the dispensers prove a non-success, would subsequently have to be abolished, and whose extinction would involve compensation. The dispensary experiment has now been twenty-four years in vogue, and has thus long since passed its probationary stage; a more adequate official recognition of the dispenser's services should therefore soon become evident, especially so as the position is regarded by the Local Government Board as "one of great importance."

G R A I N S A N D M I N I M S.

Sir,—I am much indebted to Mr. Naylor for drawing attention to the fact that in using the phrase "x grains in 100 minims" he intended "x" to mean an unknown number, and not "10," as I quoted it. This did not occur to me; had it been printed as, in the usual way, the misunderstanding would not likely have arisen. In view of this, my comments on the supposed high strength of the liquors are, of course, unnecessary; but with all deference I submit that the most important part of my criticism remains untouched. If a strength of "x grains in 100 minims" be adopted, the usefulness of the metric system will be entirely upset, no matter what the value of x may be. The relationship between the grain and the minim is such that formulae for preparations based on that relationship, and constructed on the metric system, would not be x grammes in 100 C.C., but x grammes in 91.1 C.C. or thereby. Now, this appears to me to be impracticable, and if the principle were adopted throughout the result would be "confusion worse confounded." This, at least, is my view of the proposal to introduce the metric system alongside of our present system, but altering grain measures to minims. If the times were ripe for such a change medical men should be invited to give up minims and drachms altogether, follow the B.P., and use only grain-measures; but, unfortunately, we cannot expect them to go this length yet awhile. In any case, the value of 100 should be the same whatever system we adopt; in the one it should be x grains in 100 grain measures, and in the other x grammes in 100 C.C.

Havock.

THEO. MARIN.

A n s w e r s t o C o r r e s p o n d e n t s.

[Answers to queries, which are likely to prove of general interest, will be found under the heading NOTAS AND QUERIES.]

"Pharmaceutical Chemist."—The point you mention has never been raised in a court of law, and it is not possible, therefore, to give a definite reply.

"001."—The precipitate formed is probably more or less analogous to the white substances obtained on adding ammonia, or potash in the presence of ammonium chloride, to solutions of mercuric chloride.

[For the information of several correspondents, whose communications arrived too late to be dealt with this week, it is necessary to point out that the present issue of the Journal is published a day earlier than usual.]

COMMUNICATIONS received from Messrs. Aubits, Bennett, Callis, Dakin, Greenie, Hill, Holmes, Johnston, Jones, Kirby, Leaing, Mair, Marshall, Mohunish, Park, Proctor, Rideal, Simmonds, Stanton, Surfleet, Tally, Thompson, and Wright.
EPITOME OF CURRENT EVENTS AND USEFUL INFORMATION.

Notes.

HELMHOLTZ’S VIEWS ON THE ATMOSPHERE.—A pathetic interest attaches to the letter recently received by Lord Rayleigh from the widow of Helmholtz. That profound and versatile thinker, though half paralysed during the last months of his life, yet maintained a keen interest in all scientific matters, and on hearing of the discovery of argon remarked, “I have always thought there was something more in the atmosphere.”

‘THE NATURAL HISTORY OF PLANTS.’—The twelfth part of the English edition of Kerner’s ‘Natural History of Plants’ (Blackie and Son, Ltd.) opens with further information regarding the accessory structures of the fruits of Angioperms. Those of Gymnoperms are next described in detail, after which fertilisation and the formation and natural protections of fruits receive attention. Consideration of the replacement of fruits by offshoots, parthenogenesis, heteromorphism, and alternation of generations conclude this section of the work. The portion of the next section included in this part deals with the nature of species and alteration in their form by various causes. Messrs. Blackie announce that there will be a slight delay in the publication of the next part, which will not appear until June.

ROYAL COMMISSION ON OPIUM.—It is stated, with considerable show of authority, as well as of probability, says the Financial News, that the long-delayed report of the Opium Commission will pronounced against any interference with the industry in India. The grounds of this conclusion, which is virtually unanimous, are that the alleged abuse of the drug has not been proved, and that to stop the manufacture of opium for purely sentimental reasons might entail serious social and political consequences as well as great financial derangement in India. The Commission further concludes that the cessation of imports from India would not affect the consumption of opium in China.

ROYAL GARDENS AT KEW.—The original Botanic Gardens, at Kew, of which Sir William Hooker was appointed Director in 1841, comprised about eleven acres. The following year between three and four acres was added, and in 1844, by permission of the Queen, forty-seven acres more. Further additions were made in 1846 and 1851, and at the present time the Royal Gardens are two hundred and fifty-one acres in extent. By permission of the Queen the meadow in front of Kew Palace is now to be thrown open so that visitors may obtain direct access to the finest part of the Arboretum.

PHARMACEUTICAL FELLOWSHIP.—A pharmaceutical fellowship of the annual value of six hundred dollars has been established at the University of Michigan, by Messrs. F. Stearns and Co., of Detroit, U.S.A., in accordance with the suggestion of Professor Patch at the Asheville meeting of the American Pharmaceutical Association.

AMMONIUM THIO-ACETATE.—A correspondent of the Chemical News states that on using ammonium thio-acetate in place of sulphurised hydrogen, as recommended by Schiff and Tarugi, the precipitate of cadmium sulphide obtained was reddish instead of yellow, and might easily have been mistaken for antimony. Stannic salts, again, gave brown-black stannous sulphide instead of the usual yellow stannio sulphide. Finally, a tightly-stoppered flask containing about 100 c.c. of the reagent burst, presumably by the pressure of gas given off.

NEW NORWEGIAN PHARMACOPEIA.—Considerable delay has been caused in the publication of the new edition of this book, on account of the enormous number of errors that have been found in the text. The Latin language is employed for the names of substances and directions for their preparation, but tests, etc., are given in Norwegian.

CO-OPERATIVE INDEXING OF SCIENTIFIC LITERATURE.—In March of last year the Royal Society sent out a circular letter to various institutions, suggesting that they should take part in the preparation of a complete catalogue of scientific literature, to commence with papers published on or before January 1, 1900. Amongst other bodies which received this was the Council of Harvard University, and the committee appointed by it to consider the matter reports that it finds itself fully in sympathy with the idea of establishing a catalogue of scientific literature, to be maintained through international co-operation. The opinion is expressed that some form of card catalogue can alone remedy the defects in all existing catalogues, and several suggestions are made with respect to the details of the plan proposed.

NITRO-CELLULOSE FILTERS.—In the Chemical News for April 5, H. N. Warren describes the preparation of filter papers by extracting them with hydrofluoric acid, drying thoroughly, then introducing them singly into a mixture of equal volumes of nitric acid (e.g. 1+9) and commercial oil of vitriol for five minutes, and finally washing free from acid upon a sheet of glass and dried. The result is a slightly hygroscopic paper, which burns almost instantaneously without residue, retains the finest precipitates, and yet filters much quicker than ordinary papers.

‘THE EXTRA PHARMACOPOEIA.’—The eighth edition of this valuable work of reference has just been received at the moment of going to press. It contains 581 pages, i.e., 57 more than the previous edition, published in 1892. As usual, the matter is brought exceptionally well up to date, considering the emergencies of printing. A detailed reference to the work will appear in an early issue of the Journal.
Miscellaneous News.

[Readers are invited to send local information of pharmaceutical interest. When newspapers are sent the paragraphs to be noted should be plainly marked, whilst cuttings should be verified by the addition of source and date.]

PLYMOUTH, DEVONPORT, STONEHOUSE, AND DISTRICT CHEMISTS’ ASSOCIATION.—The first annual ball in connection with the junior section of the above Association was held at the Foresters’ Hall, Plymouth, on Tuesday, the 2nd inst., and proved an unqualified success. About 100 ladies and gentlemen took part in the proceedings, and dancing commenced at 8 p.m., and kept up until 2 a.m. with great spirit. Great credit is due to the committee which arranged and successfully carried out the programme. Mr. H. O. Westcott acted as Hon. Sec. and Mr. E. W. H. Green as M.C. The music was rendered by Mr. Ackland’s orchestra, and the handsomely got up programmes were a present from Messrs. Ford, Shapland and Co.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.—A meeting of the above was held on Friday, March 29, at the Technical Institute, East Road. Mr. Alderman Deck (President) was in the chair, and there was a very good attendance of members.

Mr. Shrubbes, Teacher of Botany at the Institute, gave a very interesting lecture on “How Plants Protect themselves.” He first spoke of the struggle of plant life, followed by the “Protection of Plants from Animals and Insects of various kinds, by means of Spines, Glands, and Hairs”; and the “Insect of Plants” was also touched upon briefly.

The lecture was illustrated by various models, diagrams, and specimens, and at the conclusion the Chairman proposed a hearty vote of thanks to the lecturer, which was seconded by Mr. A. Sidney Campkin, and carried with applause.

SOCIETY OF ARTS.—The following are the papers to be read at the first four Wednesday meetings of the Society of Arts after Easter: “The Use of Electricity for Cooking and Heating,” by R. E. Crompton; “Deviations of the Compass,” by Professor A. W. Reinold; “The Extraction of the Rarer Metals from their Oxides,” by Professor William Chandler Roberts-Austen; “Means for Mitigating the Fading of Pigments,” by Captain W. de W. Abney.

SELLING ACETIC ACID ABOVE STRENGTH.—At the Clerkenwell police-court, on April 5, Alfred Homnan, chemist, of Upper Street, Islington, appeared in answer to the adjourned summons taken out by Sanitary Inspector Ward, of the Islington Vestry, for selling diluted acetic acid not of the nature and substance demanded by the purchaser. It will be remembered that the acid was stronger than the Pharmacopoeia standard, and that the magistrate took time to consider the point of law involved (ante, p. 823). Mr. Horace Smith, the purchaser, had obtained acetic acid which was partially diluted, but not so diluted as to be “diluted acetic acid” as described in the Pharmacopoeia. This preparation was, therefore, “not composed of ingredients in accordance with the demand of the purchaser, who received a stronger and more expensive dilution than he demanded. If he did not think himself injured he would have said that the Food and Drugs Act was directed against adulteration, and not against such a mistake as the present. But in a case (Knight v. Bowers, 14 Q.B.D., 845) it was held that the Section applied to sales of unadulterated articles, but which, although pure, were wholly different from the article demanded by the purchaser. In that case saffron was sold instead of saffron. It was not stated whether saffron was cheaper or dearer than saffron. It was not stated that it was immaterial whether the article sold was better or worse, cheaper or dearer, than that demanded. It was said in the judgment of Mr. Justice Mathew that it was a “wholly different article.” In the present case, at all events, the article was different from that demanded, and he was bound to convict the defendant. There was no suggestion either of fraud or even of gross carelessness, and, so far as he could see, it would be well if tradesmen were to emulate the defendant’s conduct, and give their customers, if possible, a better article than was demanded or paid for. He should, therefore, inflicts the nominal fine of 1s., and 2s. costs.

WRIGHTS AND MEASURES.—The London Chamber of Commerce has received the following letter on this subject from the London County Council: “Spring Gardens, S.W., March 28, 1895.—Sir,—In reply to your letter of the 2nd inst. on the subject of the Bill promoted by your Chamber for legalising the use of measures and weights for trade purposes, I have to inform you that the Council resolved at its meeting on Tuesday last, the 26th inst., to do all in its power to secure the passing of the Bill during the present Session. In the meantime I may say that no instructions have been given to the Council’s inspectors to interfere with the measures and weights in the execution of foreign orders, nor is there any intention to issue such instructions. I am, Sir, your obedient servant, (signed) H. De La Hooe, Clerk of the Council.”

THE DANGERS OF SOOTHING SYRUP.—At the adjourned inquest on Tuesday, March 26, respecting the death of the infant child of Alfred Price, of Wellington Street, Worcester, who had died after the administration of some soothing syrup, the public analyst for Northampton said that he had made an analysis of certain of the internal organs of the deceased, and found that there was a considerable quantity of morphine present, easily traceable in every part of the organs. He had also analysed what remained of the syrup, and had found that it contained one grain of morphine to the fluid ounce, thus giving one-eighth of a grain to the teaspoonful. The coroner produced an advertisement of the syrup, which stated that it contained but one-eighth of a grain of morphine to the ounce. Witness had read in cases in which two doses of the identical syrup (?) Winslow’s) had proved fatal to a child of fifteen months.

The coroner, in summing up, pointed out that the analysis showed that the syrup contained eight times as much poison as stated, and a dose would equal in quantity one-sixth of a grain of morphine. A much less quantity had been known to cause death. It was a pity, he thought, that medicines should be sold containing so deadly a drug, and certainly that the public should have the liberty of buying them and giving them to children, who were particularly susceptible to such poisons. He thought it was time that something should be done, and that some caution should be adopted in the sale of such concoctions.

After a short deliberation, the jury returned a verdict of “Death from morphine poisoning,” adding that they concurred in the coroner’s opinion.

The defendants, who were represented by their solicitors, protested that they had only left the parents, but to those who produced the syrup. They thought it was most dangerous to allow the unrestricted sale of such an article.

The coroner assured them that their views should be made known in the proper quarter.
Photographic Notes.

Infinitely Rapid Motions and Photography.—On Saturday, March 12th at the Royal Institution, Lord Rayleigh, in lecturing upon the multitudinous motions of the waves of the sea, and the forces which govern them in their phases, as revealed by the researches of Stokes, Thomson, himself, and others, spoke of waves upon the surface of water too small and rapid to be seen by the eye. These, he explained, can only be made visible, and could only be shown so as to be appreciated, by means of instantaneous photography, or by a series of instantaneous optical projections. Each flash of light, such as that of the electric spark, makes the object appear to stand still for a moment in one of its phases, and the flashes must be so timed as to reveal each phase so that they blend slowly, and the whole appears to be moving so slowly that the nature of the motion can be seen. He projected an enlarged image of a vibrating tuning fork upon the screen, and its prongs appeared fuzzy from the rapidity of the motion, but when the projection of the frames of properly-timed flashes of light, he so slowed down the apparent motion that each prong appeared to make but one vibration in about two seconds, so that the nature of its motion could be seen with ease. He then projected upon the screen the photographs he took three years ago of bursting soap bubbles on each taking to produce an electric flash lasting less than one-millionth of a second. The soap films were broken by means of letting a bullet, wetted with alcohol, fall through them; a dry bullet would go clean through them, perhaps, a dozen times without breaking them. The greatest difficulty in the work was in the mechanical arrangements, to so time the flash that it should occur just as the bullet had passed through the film. The photographs were good ones, showing the falling bullet, and the torn and thickened edges of the broken film, as well as some little attached filaments of liquid beads of soap solution.—Photography.

Chromatic Colour Screens.—Macfarlane Anderson states that instead of the colour screens for the production of natural colours being a hoax, as termed in a late issue of Process, last year found him ruling colour screens, or more appropriate colour filters, with the primary colours, for use in the diagram, silt, and for the mechanical work direct with one exposure. It has been pointed out that in obtaining colours by the Lippmann method, everything is endangered by the admixture of white light to the sensitive plate. The experiments undertaken have had for their object the advancement of direct colour work, and the securing of true and faithful colour delineations with one exposure. Now, by the use of a colour filter of this description any coloured image impinging on the sensitive plate registers the true vibrations, or wave lengths, suitable for the obtaining of perfect colour delineations at one exposure.—Photography.

Standard Photographic Sizes.—The "whole-plate," the "half-plate" (more than half the size of a "whole-plate"), and the "quarter-plate" less than half the size of a "half-plate" had, we have been told, their origin in the days of the daguerreotype, the dimensions of those of the size of the standard plate of copper. Whatever may be the origin of them, the fact remains that we have with us certain "standard photographic sizes," and further, that the existence of these standard sizes has been, and is, highly detrimental to photography as art, whether "decorative" or "fine." There is a difference between standard sizes of plates and standard sizes of prints.
Poisoning Cases and Inquests.

Laudanum and Prussic Acid.—Emily Onger, a widow, died on Friday, March 29, at 3, Middle Street, Clitho, City, from the effects of laudanum and prussic acid, self-administered.

Laudanum.—Martha Annie Pickering, a married woman, died on Wednesday, March 27, at Hemsworth, from the effects of an overdose of laudanum, self-administered. Verdict: "Death from an overdose of laudanum."

Vermin Killer.—Elsie Latimer, a married woman, died at Holloway Road, Droitwich, from the effects of a vermin killer, self-administered. At the inquest held on Wednesday, April 3, a verdict of "Suicide whilst of unsound mind" was returned.

Strychnine and Arsenic.—George Dixon, aged 54, died on Wednesday, March 20, at Blackburn, from the effects of strychnine and arsenic contained in a mouse powder, self-administered. Verdict: "Died from the effects of vermoden taken to produce sleep. Verdict: "Death by misadventure by taking an overdose of chloral."

Chloral.—Thomas Clarkson Wakeling, an architect, died on Wednesday, April 3, at his residence, 1, Park Terrace, Marthyl, from the effects of chloral taken to produce sleep. Verdict: "Death by misadventure by taking an overdose of chloral."

Carbolic Acid.—Severin Holme, aged 45, a Norwegian, died on Friday, April 5, in the Royal Infirmary, Liverpool, from the effects of carbolic acid, self-administered. Verdict: "Suicide during temporary insanity."

Spirit of Salt.—Mrs. Leyson, aged about 60, died on Friday, April 5, at Argyle Street, Swansea, from the effects of spirit of salt, apparently taken in mistake or spirit.

Remedies Introduced in 1894.

(Finished from p. 887.)

Fortis. — Insect destroyer.
Gallin. — Aluminum gallate. — Astringent.
Ceratoma.—Proprietary remedy for gonorrhoea.
Glycochelatin.—Ointment base.
Glycine.—A "petroleum oil" for use in atomizers.
Gusculatina.—Proprietary emulsion of cod-liver oil.
Hemalbumin.—Dietetic preparation containing the salts and albumoses of blood.
Hemoffur.—Preparation from blood.
Ulofin.—Proprietary cosmetic.
Ingestol.—Proprietary stomachic mixture.
Iodosocarin.—Antiseptic.
Iodoformin.—Derivative of formaldehyde.—Antiseptic.
Iodophenochlor.—Mixture of equal parts iodine tincture, carbolic acid, and chloral hydrate.—Parasitical dermic.
Iodoescrocin.—Succedaneum for iodofom.
Jesamodina.—Proprietary antiseptic and analgesic.
Kaputelna.—Said to be coloured anesthalid.
Katharina.—Tetrachloroethane; carbon tetrachloride.
Kephaline.—Proprietary headache remedy.
Klinel.—Proprietary antipyretic and analgesic.
Kreptolin.—Tincture Panax bark mixed with small quantities of aromatic oils.

* From the American Medico-Surgical Bulletin.
**Technical Notes.**

**Improving the Flavour of Butter.**—We have heretofore noted the experiments being conducted by Prof. H. C. Conn in the direction of discovering and promoting the right bacteria for improving the flavor of butter. He has been at this work during the past two years, and his experiments have recently been made in the production of creamery butter. As a result of these trials, it is now stated that Prof. Conn has discovered a species of bacterium, to which he has given the insignificant name of "Bacillus No. 41," and which has given the most promising results, as an organism for the artificial ripening of cream in butter making. These experiments, as carried on by him, were thoroughly satisfactory, and were made in the following manner:—One half a pint of milk was sterilised, by inoscent steaming, during a period of three or four days. Then this bacillus No. 41, which had been cultivated in the bacteriological laboratory of Weaslyan University, was inoculated into the milk, and for two days was allowed to develop. The large creamery at Cromwell, Conn., was then visited, and six to eight quarts of cream were put into each vessel and "pasteurised." The cream was then heated to 150° Fahr., and left for ten minutes. The vessel was removed and cooled quickly by means of cold water, and when the temperature had dropped to 80°, bacillus No. 41 was poured in, and the mixture stirred thoroughly. The vessel was then covered and put into the ripening room. After a couple of days the cream was churned, and the butter milk remaining was set aside for future use. These...
starch. The results obtained in test analyses have been very satisfactory.—Public Health.

HARDNESS OF WATER.—A new method of determining the hardness of water has been devised by F. Hundeshagen. He used a standard solution of sodium carbonate of 3.786 grammes to the litre, and dilute hydrochloric or nitric acid of equivalent strength; each C.C. equals 1 degree of temporary hardness (German scale). Two hundred C.C. of the water to be examined is titrated directly with the acid, using tincture of cochineal as an indicator to estimate the permanent hardness an excess of the sodium carbonate solution is added to another 200 C.C. of the water; this evaporated to dryness, and heated to about 200°. The residue is now dissolved in a few C.C. of water, filtered, and the insoluble residue in the filter washed. The filtrate is then titrated with the acid. The number of C.C. of this acid deducted from the C.C. of soda added gives the permanent hardness.—Public Health.

DETERMINATION OF MILK FAT.—In the determination of milk fat by Soxhlet’s or Asematic process, it is sometimes found that the ether separates from the alkaline solution very imperfectly, with the result that there is only small quantities to draw off. This difficulty can be easily overcome by first diluting the milk three or four times its volume with water, when the ether solution of fat separates out with the greatest ease.—Public Health.

Trade Marks Applied For.*

No. 184,883. JOLLY’S, CALIFORNIA FRUIT PILLS* with device: A bowl of fruit and address of applicants.—Pills for human use made from California fruit.—Frederick Augustus Roed, 319, Oxford Street, London. December 19, 1894. The essential particular is the device.

Filtration (Boutté, A. J.; communicated by De Mol, P., and Wilks, A.).—Relates to a process and apparatus for filtering water for drinking purposes or for filtering acids, molasses, syrups, wine, vinegar, etc. Sponges, cotton wool and the hair of certain animals, all cleansed and sterilised and so dried as to have a "great affinity for water," are used in conjunction with wood charcoal, coal dust, charred wood, and graphite or retort coals. The inventors state that the kind of hair (in the form of a felt) and of wood charcoal used, and the proportion existing between the latter and the graphite, has a marked influence upon the nature of the liquid treated. No. 2415 of 1894.

Funnels (Hollis, W. J.).—The inside of the stem is traversed by a series of longitudinal grooves or flutings which are said to facilitate filtration. No. 5116 of 1894.

Sulphuric Acid (Wacker, L.).—This acid is well-known to be produced with precipitation of carbon when sulphuric acid is electrolysed. The inventor employs a vessel with the anode and cathode preferably separated by a diaphragm, and introduces a slow stream of gaseous sulphuric acid into the anode vessel. Sulphuric acid is deposited at the cathode. The precipitation of the sulphur may be prevented by employing an oxidising agent such as chlorine water or the product obtained by treating the electrolyte of hydrochloric acid or common salt. The sulphuric acid is then supplied only in such quantity that the chlorine is always in excess. No. 8189 of 1895.
Notes and Queries.

[The Editor will be glad to receive for publication notes of practical interest to pharmacists, and will also endeavour to furnish suitable replies to any queries that may be sent by readers.]

GINGER-BEER PLANT.

[380.] The ginger-beer plant may be regarded as a very impure yeast or leaven, of a different character to ordinary brewer's yeast or German barm (of G. E. Davis, Manchester Microscopical Society's report, 1883-4). The cells are of various shapes, and are bound together by myceloid filaments which increase with the free access of air. The peculiar flavour imparted to the liquid has been attributed to small bacteroid cells.

SPICED PEPPER AND SALT.

[881.] Spiced pepper, according to Thudichum, is prepared by powdering,asting, and mixing dried thyme leaves, &; the spiced mustard, &; dried saffron, ¼ oz.; nutmeg, ½ oz.; cloves, ½ oz.; whole black pepper, ½ oz.; Nessel's paste, ½ oz. This mixture should be kept in a securely corked bottle. Spiced salt may be made by mixing spiced pepper, 1 oz. with salt, 4 oz.

DISPENSING CARBOLIC ACID.

[882.] The Cleveland Pharmaceutical Association (U.S.A.) has adopted the following formula, which is said to furnish a 38 p.c. solution of carbolic acid:—Carbolic acid crystals (U.S.P.), 16 troy oz.; glycerin, 40 troy oz. To make a 1 p.c. solution, one teaspoonful of this is directed to be mixed with 1 pint of water, and other solutions of definite percentage are easily calculated. This 38 p.c. acid mixes readily with water or alcohol in all proportions, and is much less dangerous to handle than the preparations usually supplied to the public.

THE BAKING OF BREAD.

[883.] The "ferment" added by bakers to dough made with flour consists of soluble starch, and is prepared by mixing boiled and mashed potatoes (the so-called "fruit") with yeast and some flour paste. On mixing this with flour and a sufficiency of water to produce the "sponge," the soluble starch is converted into sugar and fermentation ensues. The process is repeated when the sponge is mixed with the remainder of the flour and water to be used, and the third and final stage of panification takes place when, in the oven, the temperature of the dough approaches the point most favourable to diastatic action. The sugar formed is quickly destroyed by the yeast, and the result of the heat applied is to destroy all the ferment. The operation of bread making, therefore, involves the transformation of starch and albuminous compounds by means of ferment, accompanied by the alcoholic fermentation of sugar and the evolution of carbon dioxide. Bread contains on an average about a third its weight of water. The starch in it is partly soluble and partly insoluble, and a little alcohol remaining in the loaves evaporates slowly on exposure.

COD LIVER OIL AS A TONIC.

[884.] A preparation containing extract of malt, 1 oz.; pancreasised cod liver oil, 1 oz.; spirit of chloroform, 1 oz.; alcohol, 20 oz.; and water to 6 oz. has been recommended by T. Robinson (Lancet) as a food in building up the organism and increasing the heat of the blood. Teaspoonful doses three times daily, after meals, are administered in cases of physical and mental depression, headaches from exhaustion, subnormal temperature, etc.

Novel Uses of Drugs.

[The notes given under this heading for the information of dispensers, embody recent suggestions in therapeutics, and cover both new remedies and old ones under new aspects.]

ANTIPYRINE MANDELATE IN WHOOPIING COUGH.—A combination of antipyrine and mandelic acid, found useful in cases of whooping cough. In children, a year take 0·05 to 0·10 Gm.; between 3 and 5 years, 0·25 to 0·50 Gm. (Renn, München. med. Woch., Nov. 13, 1894)."
THE CYANO-CUPRIC TEST FOR DETERMINATION OF GLUCOSE.

BY A. W. GERRARD.

At the meeting of the British Pharmaceutical Conference held at Edinburgh, 1892, I communicated a paper on "A New Method for the Estimation of glucose," the details of which will be found in the 'Year-Book of Pharmacy,' 1892, p. 400; and Pharm. Journ. [3], xxiii, 208. In the discussion which followed it was feared that the reagent employed, if used as indicated, would not keep well. Such, after ripen experience, has proved to be the case; notwithstanding this defect, however, further experiments have enabled me to so far modify the test as to make it as perfect as can be desired. The method is based on the following facts:

If a solution of copper sulphate a solution of cyanide of potassium is added until the blue colour is just gone, a double cyanide of copper and potassium is formed, as follows:—

$$\text{CuSO}_4 + 4\text{KCN} = \text{CuCN}_2 \cdot 2\text{KCN} + \text{K}_2\text{SO}_4$$

This double cyanide is a salt of considerable stability. It is not decomposed by alkalies, sulphuretted hydrogen, or ammonium sulphide. With mineral acids it gives a whitish curdy precipitate. If in place of a solution of copper sulphate the cyanide be added to Fehling's solution, the blue colour vanishes and the same double cyanide is formed, but the product when boiled with reducing sugars gives no precipitate of cuprous oxide. If, however, the Fehling's solution be present to double the amount decolorised by the cyanide, the mixture will now be blue and suffer reduction when boiled with glucose, giving no precipitate of cuprous oxide, but a steady disappearance of blue colour; behaving in this respect like Favy's solution.

My original paper a formula was given in which Fehling's solution of double the usual copper-strength was used, adding to it enough cyanide of potassium, of specified strength, to decolourise half the copper. This method, which proved troublesome, has now been discarded for the more simple and accurate one which follows:—10 C.C. of Fehling's solution, or 5 C.C. each of the separately kept solutions of copper and alkali, are placed in a porcelain dish with 40 C.C. of water, then boiled. To the hot mixture add steadily from a pipette some 5 per cent. solution of potassium cyanide until the blue colour just fades, or a very faint blue colour only remains. Excess of cyanide must be carefully avoided. A second 10 C.C. of the Fehling's solution is now added, and whilst the mixture is kept boiling run in the solution of urine or sugar from a burette, until the blue colour is gone. It is important to keep the mixture well boiling, to add the urine steadily, and watch sharply for the change. The volume of fluid in C.C. used to remove the colour will contain 0.50 gramme of glucose, so that if 10 C.C. per cent. the amount of sugar present is 0.50 gramme.

Solutions containing above 5 per cent. of sugar should be diluted ten times before testing, and the resulting figures multiplied by ten.

Those who are accustomed to frequently examine diabetic urines, are well aware of the difficulty of determining small amounts of sugar by Fehling's test, with anything like satisfaction.

The copper gets into an extremely fine and yellow coloured condition almost impossible to filter off, making it extremely difficult to judge of the end reaction. In such cases the cyano-cupric test will be found very useful. Further, it has the advantage over the ammonia test, that in there are no fumes to annoy the operator, and the boiling may be done in an open dish.

In working out this revised process, I am much indebted to Mr. A. H. Allen, of Sheffield, for his assistance. Mr. Allen fully confirms the simplicity, accuracy, and convenience of the test.

EXPERIMENTS WITH EGG ALBUMIN.

BY E. J. EVANS.

The following experiments were conducted in the laboratory of the University College of Wales, Aberystwyth, and were undertaken with the view of comparing the relative merits of the various tests for the detection of albumin.

Six tests were employed in each case, viz.: (1) heat test; (2) acetic acid; (3) nitric acid; (4) picric acid; (5) ammonium nitrate-bichromate; (6) uranous oxide dissolved in acetic acid.

(a) The strength of the first albumin solution was 1 in 40.

8 C.C.'s of this solution was dropped into each of six test tubes from a 50 C.C. burette.

The results were as follow:—

1. Heated to boiling. Coagulation and slight opalescence was observed.
2. Heated with the addition of a few drops acetic acid. Coagulation and more opalescence.
3. Heated with a few drops of nitric acid added. Formation of a cloudy precipitate, which became denser on heating.

(b) A second solution was then prepared containing 1 in 200—

1. Heated to boiling. Formation of white froth on the top of the solution.
2. Heated with a few drops of acetic acid. As above, with slight coagulation.
3. Nitric acid test. A white, cloudy precipitate in the line of the drops of HNO₃ and on shaking a white opalescence.
4. Picric acid test. Yellow opalescence, more distinct than No. 3. On heating after standing some time, yellowish precipitate separates out.
5. Molybdate test. White, cloudy opalescence in the cold.

(c) The third solution contained 1 in 1000.

1. Heat test. Slight froth; no opalescence.
2. Acetic acid test. Same.
3. Nitric acid test. Same.
4. Picric acid test. Slight yellow opalescence, increased by heating.
6. Uranium test. Yellowish opalescence, becoming cloudy on standing and settling down as a white precipitate at the bottom of test tube.

(d) A fourth solution was made one half the strength of the third solution.
The same reactions were obtained with (4), (5), and (6), but less definite.
The limits of these tests seem to lie between 1/2500 and 1/5000, and it is hard to decide which of the three is the most delicate.
My own opinion is in favour of the molybdate, next comes the uranium, and then the picric.

NOTES ON PEPSEIN TESTING.*
BY L. A. HARDING, B.S.C., PH. D.

It has always been claimed that pepsin possessed great digestive power, and we have been taught that its proteolytic action was practically the only criterion of its value, yet from recent observation we are forced to admit that the real proteolytic action of pepsin is but very small, and it appears questionable as to how far we can admit this digestive property.

We say such and such a pepsin has a digestive power of, say, 1 to 2000 or 1 to 4000, as the case may be, and we understand by this that one grain of pepsin is capable of digesting or dissolving 2000 or 4000 grains of hard boiled egg albumin under certain conditions. These conditions we usually admit to be a sufficient quantity of a 0.2 per cent. solution of absolute hydrochloric acid and a water bath digestion of five or six hours at a temperature of between 100° and 105° F., and by the result of this operation we are taught to gauge the comparative value of a pepsin. It is perhaps the only practical method which we at present can employ to ascertain the real proteolytic power of a pepsin, but this method of procedure and the result obtained are unquestionably erroneous.
Our best workers in this line have long since recognised this fact and have advocated the idea of measuring the value of a pepsin by the amount of pepperine it is capable of producing and not by the quantity of albumin digested, for if we consider the fact that 2 ounces of a 0.2 per cent. solution of absolute hydrochloric acid, under the conditions mentioned above, can digest 128 grains of albumin out of 200 employed, being at the rate of 63 per cent., it is obvious that the pepsin must play but a very small part in the digestion of the albumin.

ALBUMIN SOLUBLE IN HYDROCHLORIC ACID ALONE.
The idea of coagulated egg albumin being soluble in an acid solution without the aid of pepsin has been contested by some writers upon this subject, and especially by Dr. Tscheppe, whose conclusions are based upon the idea that owing to the natural alkalinity of the egg albumin a portion of it escapes coagulation by transformation into alkali-albumin, and that the solubility is due to this phenomenon.

It seems scarcely probable, however, that 63 per cent. of the egg albumin should be converted into alkali-albumin. Furthermore, this view seems strangely in opposition to that of Prof. Harnack, of Hallé, who claims to have isolated pure albumin, and who has stated that it would not coagulate by heat except in the presence of alkalies. The fact, nevertheless, still remains that if an acid solution can dissolve egg albumin without the aid of pepsin, it certainly can perform the same function with the addition of the pepsin. Dr. Tscheppe further maintains that if the floccular coagulum obtained from a strained solution of albumin by heat under addition of the proper amount of acid be thoroughly washed and then digested with a 0.2 per cent. solution of hydrochloric acid at incubation temperature, it would be found that not enough can be dissolved after twelve hours to yield a reaction with lodo-hydrargyrate of potash.

While we do not question the correctness of this assertion, yet it is not stated that one grain of pepsin is able to digest 2500 grains of this so prepared egg albumin, and so long as we employ the egg albumin in a different form from that just mentioned, just so long must we consider the question in hand from that point of view.

HAS PEPSEIN ANY REAL PROTEOLYTIC ACTION?
As mentioned before, from recent experience we must deny any real proteolytic power of pepsin upon egg albumin. This is the conclusion arrived at by working with peptins having a claim of 1 to 2000 and 1 to 2500. What it would be with a pepsin of absolute purity we need not stop to consider, as pure pepsin, or the absolute active principle of the gastric ferment, has as yet not been isolated.
The results of my experiments may be summed up as follows, and I will state that a sufficient number of experiments has been made to confirm the correctness of the statement.

EXPERIMENTS.

First.—The pepsin employed was claimed by the manufacturers to be able to digest 1 to 2500. Acid solution employed, strength 0.2 per cent. absolute hydrochloric acid; time of digestion, six hours; temperature, 100° to 104° F.; average amount of albumin digested in five successive trials, 1540 grains.

Second.—Conditions and material the same as in the first instance cited, excepting that no pepsin was used; the quantity of albumin digested on an average of six successive trials being 1280 grains, leaving a difference in favour of the pepsin solution of 280 grains, a practically dissolving only about 9 per cent. of the amount claimed.

Now, the question might be asked, Why is it that you stated that pepsin was devoid of any digestive power, and yet you here admit that it digests about 63 per cent. of the albumin used? But I do not admit anything of the kind, as I account for the difference noted by the hypothesis that the pepsin converts part of the syntonin into a peptone, thus giving the remainder of the syntonin, if any more is formed, a chance to enter into solution, which could not be the

* Reprinted from the American Druggist.
case were the solution of syntonin already in a saturated state. The acid solution in this case converts the albumin into sytonin, from which it is converted into a peptone by action of the pepalin. This is the only credit that can be accorded to the pepalin.

THE STATE OF DILUTION.

Another important factor is the amount of acidulated water used. It must be borne in mind that no more should be used in testing the pepalin than is absolutely necessary. The proper proportion seems to be 1 ounce of acidulated water to 100 grains of albumin. Nearly all authorities, such as Clark, Hirsch, Schneider, Geisler, etc., agree on this amount of acid solution, and so long as we simply aim at the digestion of the albumin we should endeavour to ascertain what quantity of solution is necessary to dissolve a given quantity of albumin, and not what weight of albumin will be digested in an excessive quantity of water. Clark states (Pharm. Journ. and Trans., January, 1892, p. 597) that the amount of acidulated water used is an important factor; as no limit can be given, to that extent the digestive power of the same pepalin will vary. Of course we have Geisler on the other hand, who recommended 100 C.C. of acidulated water for 10 grains (7 grammes) of albumin; but note, he also directed that the digestion be carried on only three hours. There are some who advise the use of nearly double the quantity of solution, but it should be borne in mind that if double the quantity of liquid is used this involves doubling the quantity of acid, and the result should be that double the quantity of pepalin is dissolved.

The whole matter of pepalin testing as practised at the present time is, it seems to me, only a delusion, for my claim that albumin is soluble in acid solution, without the aid of pepalin, is based upon actual facts, arrived at through actual work, and not jumped at simply through a baseless hypothesis. The time will come, and I believe it is near at hand, when we shall go a step further and gauge the value of a pepalin by the amount of peptone it is able to produce and not by the quantity of albumin there is dissolved in acid media of which it happens to be a part.

FLAVOURING EXTRACTS AND SYRUPS.*

BY GALEN, JUN.

EXTRACT OF VANILLA.

This is nothing more than a misnomer for tincture of vanilla, and if the pharmacopoeial directions for the preparation of this article be followed a satisfactory article will result; but for the benefit of those who prefer to use a different preparation, we append the following formula:—

**Vanilla Essence I.**

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vanilla essence</td>
<td>fl. 3 iv</td>
</tr>
<tr>
<td>Solution of caramel</td>
<td>fl. 2 ij</td>

<tr>
<td>Solution citric acid (50 per cent.)</td>
<td>fl. 3 j</td>
</tr>
<tr>
<td>Tincture curcula</td>
<td>q. s.</td>
</tr>
<tr>
<td>Simple syrup</td>
<td>Cong. j</td>
</tr>
</tbody>
</table>

**ORANGE SYRUP II.**

Take six good oranges and rub the oil from the rind by means of cut loaf sugar. After doing this the juice of the oranges is squeezed into about four or five pints of foamed stock syrup. The sugar used to extract the oil is placed in syrup and the whole heated gently to dissolve the sugar; then strain. If desired for blood-orange, colour with raspberry juice or tincture of curcula. The rind will readily give up its oil to the sugar, then add foamed syrup to make one gallon. In case the oranges are unusually sweet acidify with citric.

**ORANGE SYRUP III.**

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oranges</td>
<td>No. vj</td>
</tr>
<tr>
<td>Tincture quillala</td>
<td>fl. 3 iv</td>
</tr>
<tr>
<td>Loaf sugar</td>
<td>fl. 3 x iv</td>
</tr>
<tr>
<td>Water, sufficient to make</td>
<td>Cong. j</td>
</tr>
</tbody>
</table>

Grate the oranges lightly and macerate the gratings in a quart or more of water; throw the whole on a flannel filter, then pass enough water through, when added to the orange juice, to make four pints; finally add this to the sugar contained in a conical percolator and dissolve by percolation. The tincture of quillala is added to the finished product.

**ORANGE SYRUP IV.**

Grate the outer peels of six large oranges and rub the gratings with 8 ounces of loaf sugar. To this add half gallon of syrup, stir thoroughly until the sugar is dissolved, and strain. Add the expressed juice of the
oranges and 1 fluid ounce of a 50 per cent. solution of citric acid to the strained solution, and, lastly, add sufficient syrup to bring the bulk up to 1 gallon, and use without form.

**BLOOD ORANGE.**

Orange essence (as above) ....... fl. $\frac{3}{4}$j
Solution citric acid .............. fl. $\frac{3}{4}$j
Raspberry juice .................. fl. $\frac{3}{4}$lij
Simple syrup, to make .......... Cong. j.

Mix and strain through flannel.

**LEMON SYRUP I.**

Take two large, sound lemons; grate the peel and triturate with 2 ounces of sugar of milk and 1 pint of hot simple syrup. Shake thoroughly, and when cold add the expressed juice of the lemons, 1 ounce of solution of citric acid (50 per cent.) and sufficient syrup to bring the total bulk up to 1 gallon.

**LEMON SYRUP II.**

Lemons .................................. No. viij
Alcohol .................................. fl. $\frac{3}{4}$j
Solution citric acid ................. fl. $\frac{3}{4}$j
Loaf sugar ............................... $\frac{1}{2}$olx
Water ...................................... 0 x
White of egg ............................. No. viij

Grate the peel of lemons and extract the flavour with the alcohol. Express the juice, and after mixing both together, add the sugar and water, and dissolve by heat. When cool add the solution citric acid and white of egg. The white of egg should be beaten to a froth before adding to the syrup.

**CHOCOLATE SYRUP I.**

Powdered chocolate ................. $\frac{1}{4}$w
Powdered cocoa ........................ $\frac{3}{4}$j
Cold water .............................. $\frac{3}{4}$x
Simple syrup ........................... Cong. j.

Mix the chocolate powders and make into a thin paste with the water. Heat the syrup to the boiling point and add the watery thin stream, stirring vigorously. Use without straining.

**CHOCOLATE SYRUP II.**

Powdered chocolate ................ $\frac{1}{4}$lij
Water .................................. $\frac{1}{4}$ij
Vanilla essence ........................ fl. $\frac{3}{4}$j
Simple syrup ........................... Cong. j.

Triturate the chocolate with sufficient hot water to form a smooth paste; then add the syrup and heat to the boiling point. When cool strain through cheese cloth and add the vanilla essence.

**CREAM CHOCOLATE I.**

Chocolate .................. $\frac{3}{4}$lij
Condensed milk ................. 1 can
Loaf sugar ........................ $\frac{1}{4}$lij
Vanilla essence ....................... fl. $\frac{1}{4}$is
Whites of egg ........................ No. ij

Triturate the chocolate with sufficient water to form a paste and add to remainder of water in which has been dissolved the other ingredients.

**CREAM CHOCOLATE II.**

Chocolate .................. $\frac{1}{4}$v
Cocoa ................................. $\frac{3}{4}$j
Cold water .............................. $\frac{3}{4}$j

Mix and add:

Condensed milk ...................... $\frac{3}{4}$vij
Borax acid ............................ $\frac{3}{4}$ij
Stock foam syrup ..................... Cong. j.

Stir well; boil one minute, and use without straining.

**COFFEE SYRUP I.**

Mocha and Java coffee, of each ........ $\frac{3}{4}$vij
Put the mixed coffees in a percolator and add:

Boiling water ......................... $\frac{3}{4}$v

Allow the coffee to macerate about twelve hours before starting percolation; then percolate to five pints.

For hot soda add:

Sugar ................................ $\frac{1}{4}$xxx

For cold soda:

Sugar ................................ $\frac{1}{4}$xxvxij
Condensed milk ...................... $\frac{3}{4}$vij
Caramel solution ................ q. s.

**COFFEE SYRUP II.**

Fluid extract coffee ................. fl. $\frac{3}{4}$vij
Citric acid ........................... $\frac{1}{4}$ij
Syrup ................................. Cong. j.

Dissolve and mix.

**RASPBERRY SYRUP.**

Raspberry juice .......................... $\frac{1}{4}$ij
Loaf sugar ................................ $\frac{1}{4}$vij

Dissolve the sugar in the juice with the aid of heat; strain and transfer to a bottle, labelled.

**CONCENTRATED SYRUP.**

To prepare for fountain use add one quart of this syrup to two quarts of simple syrup and three fluid drachms of solution of cochineal or a lesser amount of carmine solution.

**SYRUP FOAM.**

Gelatin makes one of the nicest and cleanest foams for soda syrup, the brand known as Cox’s being excellent for this purpose. Gelatin foam has the advantage of ease of preparation and does not seem to interfere with the keeping qualities of the syrup, while the foam produced is all that could be desired. It has many points of superiority over soap bark or egg albumin. One-half ounce of gelatin to the gallon of syrup will usually be found sufficient.

**THE SOLUBILITY OF QUININE IN ALKALIES.**

*BY PROFESSOR E. DUCMER AND E. DERAY.*

Whilst carrying out some experiments in another direction we noticed that quinine was appreciably soluble in alkaline liquids, and the idea occurred to us to investigate quantitatively the importance of this solubility. This research is not without interest, for the precipitation of quinine by alkalies is frequently made use of not only in the manufacture of quinine commercially, but also in the laboratory for the determination of this alkaloid.

It has, of course, been known that quinine is not entirely insoluble in alkaline liquids, and in demonstrating that this solubility does exist we lay no claim to advancing a statement which is entirely new; on the other hand, it is the importance of this solubility, and the relation which the strength of the alkaline liquid bears to the amount dissolved, which has been neglected. The object of these investigations has been to determine the weights of quinine which can be dissolved by liquids containing known weights of alkalies.

It was hardly to be expected that in order to determine this solubility we could take an accurately weighed quantity of pure, dry quinine, saturate with

*From the *Journal de Pharmacie et de Chimie.*
it a known volume of an alkaline liquid, the strength of which had been very exactly determined, collect the quinine which was undissolved on a filter, wash, dry, and afterwards weigh it; indeed, by this process we should have multiplied the sources of error, some of which would have been sufficient to depreciate the value of our results. We have preferred another method of procedure which has this advantage over the foregoing, that it is first of all quicker, and in addition, only allows of one source of error. The process which we have employed is as follows:—Pure sulphate of quinine was dissolved in water which had been acidulated with just sufficient hydrochloric acid; this solution was added drop by drop to a known volume of an alkaline liquid, the strength of which had been very accurately determined, and this was constantly shaken. Proceeding thus, it is noticed that the quinine solution causes a precipitate which at first quickly redissolves in the alkaline liquid, but afterwards more and more slowly until the precipitate is permanent. If care has been taken to measure accurately the volume of the solution of quinine introduced into the alkaline liquid without producing a permanent precipitate, the weight of quinine dissolved in the volume of alkaline liquid used can be easily calculated.

This is the basis of the method which we have followed. Its accuracy, however, is not beyond criticism. Objections may be brought against it on the ground that the alkali of the solution forms salts with the acids of the quinine solution, whose solvent power on the quinine is perhaps not all. But if it be noticed that the weight of sulphate of quinine, which must be introduced in order to obtain a permanent precipitate, is always relatively small, and that consequently the weight of the alkaline sulphate and hydrochlorate thus formed is almost negligible, it will be seen that this objection loses much of its value. Another objection, more important than the first, can perhaps be advanced. It may indeed be said that it is very hard to fix the exact moment when the precipitate is permanent; this, in fact, constitutes the greatest difficulty of the process. Practically this constitutes an insuperable objection to absolute determinations, but for comparative tests, analogous to those which we have carried out, in which we have confined ourselves to the regular use of the same volumes of alkaline liquid, it is of less moment so long as it is stipulated that each test is carried out under precisely the same conditions. Thus in all the following statements it is to be noted that we stopped at the moment when the alkaline liquid, kept constantly shaken, at the end of two minutes after the last addition of the quinine solution, had a milky appearance similar to that obtained by diluting 1 C.c. of milk with 100 C.c. of water. Thanks to these precautions, the results published in the following tables are sufficiently comparable with each other.

In all our experiments we have used a solution of sulphate of quinine containing exactly 1 gramme of sulphate of quinine in 100 C.c. of liquid.

**AMMONIA.**—In the following table the first column shows the weights of ammonia contained in 200 C.c.; the second, the volumes of the solution of quinine absorbed by the alkaline liquid; the third, the weights of anhydrous quinine absorbed; and the fourth the weight of quinine absorbed per gramm of ammonia.

The results shown by this table are first, that the weight of quinine dissolved increases in proportion to the strength of the alkaline solution, and that with a comparatively weak solution (containing, for instance, 2 per cent. of ammonia) the proportion of anhydrous quinine dissolved per 100 C.c. is far from being unimportant, since it corresponds to 0.048 grammes. This conclusion can therefore be drawn—that in the precipitation of quinine, it is best to use as little ammonia as possible. If we consider the figures contained in the last column we shall see that the weight of quinine absorbed, when referred to the unit of weight of ammonia, varies inversely as the strength of the alkaline liquid, and in an enormous ratio. Thus, since very weak ammoniacal solution will absorb 0.163 grammes of quinine per gramm of ammonia, a very concentrated solution will not absorb more than 0.006 grammes per gramm of ammonia. From this we conclude that it is best to use an ammoniacal solution as concentrated as possible.

To sum up, it is best to use a very small quantity of a very concentrated solution of ammonia in order to have as little loss as possible in precipitating the quinine.

Let us take for example the precipitation of 1 gramme of quinine as sulphate, dissolved in 100 C.c. of water. If this is precipitated with 100 C.c. of 25 per cent. ammonia we shall only recover, after precipitation, about 1 gramme less 0.17 grammes, that is to say, 0.83 grammes; if, on the contrary, we precipitate the same with a solution of ammonia of but 4 per cent. strength, but the same bulk of liquid, we shall recover an amount of quinine equal to 1 grammes less 0.08 grammes, that is to say, 0.92 grammes. From this it will be seen how important is the effect which the quantity of ammonia used has on the determination of quinine.

**POTASH AND SODA.**—Caustic potash and soda also dissolve quinine to an appreciable extent. But, as the following tables show, contrary to what is seen with ammonia, the solubility of quinine in potash and soda solutions is greater in proportion as the strength of these solutions is less. The potash and soda used was prepared by alcohol.
Table II.—Soda.

| Weight of | Volume of | Weight of | Weight of |
| soda, contained | solution of | anhydrous | quinine absorbed per gramme of |
| in 200 C.C. | quinine | quinine | soda. |
| 0·007 | 12·4 | 0·092 | 12·143 |
| 0·012 | 12·3 | 0·091 | 7·383 |
| 0·040 | 12·0 | 0·090 | 0·122 |
| 2·160 | 10·6 | 0·079 | 0·06 |
| 3·188 | 7·5 | 0·066 | 0·018 |
| 6·172 | 5·9 | 0·044 | 0·007 |
| 8·537 | 2·8 | 0·021 | 0·002 |
| 17·074 | 2·0 | 0·015 | 0·001 |

Table III.—Potash.

| Weight of | Volume of | Weight of | Weight of |
| potash, contained | solution of | anhydrous | quinine absorbed per gramme of |
| in 200 C.C. | quinine | quinine | potash. |
| 0·612 | 11·9 | 0·088 | 0·144 |
| 1·512 | 11·0 | 0·082 | 0·064 |
| 3·466 | 9·2 | 0·068 | 0·020 |
| 10·944 | 5·3 | 0·059 | 0·004 |
| 44·704 | 0·3 | 0·006 | 0·0001 |

As may be seen, the solubility diminishes in proportion as the strength increases. It is true that it cannot be stated that this difference is essentially due to the nature of the alkali; for although we can obtain very pure ammonical solutions, the case is not the same with potash and soda solutions, which, no matter how made, always contain variable proportions of carbonate, and it will subsequently be seen how important an influence this body exerts upon the solubility of quinine. However that may be, we can, from a practical point of view, draw this conclusion—that the precipitation of quinine by potash and soda will be more complete in proportion as the weight of alkali used is greater and dissolved in as small an amount of water as possible.

*(To be continued.)*

**NOTES ON RECENT SCIENTIFIC INVESTIGATION.**

**CONSTITUENTS OF CASSIA OIL.—**The existence of a crystalline "cassia-stearopten" in cassia oil was first noted by Roehlde in 1850, and Bertram and Künsten (Journ. für Prakt. Chem., I., 316) have separated and identified this substance. By the reactions of this substance they arrived at the conclusion that it was ortho-cinnaraldehyde-methyl-ether—

\[ \text{C}_8\text{H}_8\text{OMe} \text{+ CH}_2\text{CHO} = \text{C}_8\text{H}_8\text{CH}-\text{CHO} + \text{H}_2\text{O}. \]

The product thus obtained being identical in all respects with that obtained from cassia oil, the constitution of the stearopten is conclusively proved.

**ACETYLATION OF SUGARS.**—It has been shown that the sugars are easily transformed into their acetic esters by reaction either with aceto anhydride and sodium acetate (Liebmann), or with aceto anhydride and zinc chloride (Franchimont). Tarret (Bull. Soc. Chim., xiii., 261) has studied the action of these different acetylating agents on various members of the sugar group. When inositol and other sugars not easily inverted react with these reagents, the action is the same in each case, both with regard to the ester formed and the yield. With saccharoses and polysaccharides easily inverted, such as saccharose, raffinose, etc., the true acetic esters of the sugar are formed by acetylation with aceto anhydride and sodium acetate. If, however, zinc chloride and aceto anhydride be used, esters are obtained which differ in rotatory power and other physical properties from those obtained by acetylation according to Liebmann's method. The esters thus obtained are those of the glucose derived from the corresponding saccharose by hydration. The action of the esters on these two acetylating agents differs with the saccharoses. When the two acetylating agents reacted with the sugars, discordant results were obtained by different investigators. It appears however, that by varying the amount of sodium acetate and zinc chloride present, three different esters were obtained. The cause of these differences is still under investigation.

Instructions from Members, Associate Members, and Students respecting the transmission of the Journal must be sent to the Secretary — Mr. Richard Brambridge, 17, Bloomsbury Square, London, W.C.

CONSUMPTION AND ITS PREVENTION.

The prevention of disease is of even greater importance than its cure, since the necessary precautions concern everyone, whilst the invalided and those interested in their treatment constitute only a comparatively small number. And, though the realisation of the idealist's dream of the total extirpation of disease would seem to carry with it the removal of the occupation of medical men and pharmacists, in reality it would but tend to indefinitely extend their sphere of usefulness. For the more hygienic restrictions and regulations are multiplied, the greater will be the need of an army of well-trained experts, and the highly educated medical man and pharmacist will be the persons best adapted to fulfil the functions of such.

No apology, therefore, is needed for introducing to our readers some of the facts and opinions recorded by Dr. William Murrell in his Clinical Lectures on the Prevention of Consumption, recently delivered at the Westminster Hospital and now reproduced in book form by Messrs. Baillière, Tindall and Cox.

Statistics show that one person in every eight in this country dies from phthisis. During the years 1848 to 1880, inclusive, the deaths recorded as due to this disease exceeded 51,000 per annum, and in 1899, when the death-rate from phthisis was the lowest on record, the number registered in England and Wales was 43,323. Cancerous disorders were responsible for 20,353 deaths during the same year, and the whole of the zymotic diseases for £8,009, whilst there were only about 16,000 fatal cases from accidents. It is clearly apparent therefore that consumption easily heads the list of mortality from any one cause. As Dr. Murrell pertinently indicates, also, the disqualifying power of the disease is enormous, patients who suffer from it surviving and requiring more or less attention during an average of something like five years, and it is assumed that there are at the present time from 150,000 to 200,000 people suffering from the disease in England and Wales. The causes of its great prevalence are numerous and not far to seek. In the first place phthisis is undoubtedly communicable. Husbands and wives communicate it to each other, and patients to nurses; whilst soldiers, sailors, and others in confined quarters readily acquire it when associated with affected persons. The air exhaled by patients and dried sputum disseminated in dust appear to be the main sources of contagion. Beds, sleeping apartments, railway carriages, and ship cabins, used by patients, probably act as secondary agents, whilst omnibuses plying on the routes leading to and from consumption hospitals have been described as veritable death traps. Investigation has also proved that phthisis can be inoculated and that it is communicable from the lower animals to man. In the case of the hest of children who die of tubercular disease, much of the mortality appears to be due to the use of milk from tubercular cows, and imperfectly cooked tubercular meat is also doubtless responsible for the spread of the disease. In this connection it is interesting to note that Koch's tuberculin has proved of value as a diagnostic agent. In New York and Denmark it is injected into suspected animals, which are forthwith killed if the temperature rises markedly afterwards; this being considered sufficient evidence of the existence of the disease.

The chief preventive measures recommended by Dr. Murrell are the inclusion of consumption in the list of notifiable diseases, the disinfection of rooms, &c., used by consumptive patients, the removal of consumption hospitals to the outskirts of large towns, the rejection after inspection of tubercular meat and milk, the inspection of herds, and the prevention of overcrowding amongst animals intended for consumption as food. Overcrowding should also be prevented amongst the population, houses and other buildings need to be built so as to admit the maximum of light and air, and dusty occupations ought to be regulated. Much may also be done by personal effort. Thus, healthy persons should refuse to sleep in the same room with phthisical patients, the temperature of such rooms should not be too high, and they should be efficiently ventilated. Recipients of expectorated matter ought to contain a good disinfectant, and the contents be afterwards destroyed by fire. The thorough disinfection of patients' linen is also essential. Nurses should get out in the fresh air as much as possible, food be well cooked, and milk boiled previous to use, whilst people predisposed to phthisis should exercise care in the selection of a
residence or occupation, and in their general mode of life. There is little doubt that all the precautions suggested will be found more or less necessary before there is any decided check to the progress of phthisis, and Dr. Murrell is to be congratulated on putting his case so clearly as to be quite comprehensible to even non-technical readers.

SCIENCE PROGRESS.

Special interest attaches to several of the articles in the April number of Science Progress. In the first, Professor C. S. Roy, of Cambridge, bases a series of observations on notes by Mr. W. M. Conway of his experiences in the Karakoram Himalayas, more particularly with regard to the symptoms termed mountain sickness (Fr. mal des montagnes; Ger. Bergkrankheit). These symptoms become more distressing in proportion as a height of 16,000 to 17,000 feet is exceeded, and may become so dangerous as to endanger life. They include difficulty of respiration accompanied by great distress, palpitation of the heart, severe headache, giddiness, nausea with or without vomiting, bleeding at the nose, lividity of the face, etc., etc. Professor Goebel, of Munich, dealing with the metamorphosis of plants, states that, though division of labour does not necessarily involve metamorphosis, it may certainly be regarded as a condition of its manifestation. Physiological requirement would appear, therefore, to be the main factor in effecting structural differentiation, whilst the particular organ to undergo modification will be that most susceptible to a change in the desirable direction. H. A. Mirrants explains how the nature of the symmetrical repetition in space of its ultimate parts, which confers on matter the symmetry shown by crystals, has been ascertained; and A. W. Bennett discusses the meaning of the term “tendency,” as employed in biology, with the object of showing that accepting Weinmann’s definition of “acquired characters,” there is in those characters a hereditary factor which renders it impossible to draw any satisfactory distinction between them and “non-acquired” characters. The subjects of the remaining articles are on “Spanish Anthropology,” by John Budden, “The Coagulation of the Blood,” by Professor W. D. Halliburton, and “Recent Contributions to the Geology of the Western Alps,” by J. W. Gregory.

DOCTORS V. CHEMISTS.

In these days of overcrowding and competition, remarks the Sunday Times, in an unusually sympathetic mood, the medical profession suffers more perhaps than any other calling in the country. “It has many attractions of the highest and noblest kind, which appeal to an ever-increasing number of people, besides which it offers not a few rich prizes to the ambitious and the money-loving. But it is melancholy to reflect upon the condition of thousands of doctors throughout the country, thoroughly capable men who cannot get sufficient practice to enable them to live in a style expected of their profession.” According to our contemporary, a member of the medical faculty attributes the present state of affairs to the growing practice among chemists of prescribing for customers, thus depriving the general practitioner of patients; though with a burst of humour it is remarked that it might be imagined that this practice would provide him with not a few. In the opinion of this practitioner a society should be formed to protect doctors from the prescribing chemist, but, as the Sunday Times points out, it must be remembered that such a society, without the aid of the public, could effect but little good, for its success would depend entirely upon the evidence of informers. It may also be suggested that the fact is lost sight of that, even if prescribing by chemists were totally extinct, there would yet be more doctors than are required. All the professions are overcrowded with men who may, in some respects, be considered “thoroughly capable” but yet somehow fail to hit the mark, and they would therefore seem to have missed their proper vocation.

PHARMACEUTICAL DEGREES.

The Pharmaceutische Rundschau gives a historical sketch of the steps that have been taken in the United States in reference to the creation of degrees for pharmacists. The title of “Graduate in Pharmacy” is now commonly used there, but the prevailing tendency appears to be mainly in the direction of conferring the title of “Master in Pharmacy” or “Doctor of Pharmacy.” The Philadelphia and New York Colleges of Pharmacy have actually decided to introduce the latter title, and the Rundschau regrets the innovation, deeming it a grave error. It rightly contends that the creation of a class of Doctors in Pharmacy, without legitimate academic recognition, must both fail to bring any advantage or prestige to the Colleges, and to raise the standing of pharmacy in public estimation, whilst it is bound to aggravate the already strained relations between medical men and pharmacists.

EVENING MEETING IN EDINBURGH.

An Evening Meeting of the Pharmacetical Society will be held in the Society’s Hall, 36, York Place, Edinburgh, on Friday, April 26, at 8.30, Mr. J. Laydlaw Ewing in the chair. The following papers will be read:

“Ferrous Phosphate,” by George Coull, B.Sc.
“Note on Commercial Linseeds,” by A. J. Day and W. B. Cowie.
Transactions of the Pharmaceutical Society of Great Britain.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The present session of discussions and meetings promoted by this Society was brought to a close on Wednesday, April 10, when Mr. S. T. Rhoden read a paper on "Examinations and the Relative Positions of the Teaching and Examining Bodies." Mr. J. F. Hardley, the President, occupied the chair.

At the outset Mr. Rhoden maintained that the charge of apathy on the part of the outside members of the profession, so often deplored by the well-wishers of the Pharmaceutical Society of Great Britain, did not apply to Sheffield, where the members of the craft were ever ready to take an interest in or to express a decided opinion upon any questions affecting their position or welfare. Defining examinations as a process of a manifold character, he said the purpose of examinations, with which he intended to deal, was that which determined whether the examinees should receive the necessary legal qualification to prosecute the avocation of a pharmacist. After describing the varied objects of examinations, he went on to describe the position of the teaching bodies as one of the greatest responsibility and delicacy, inasmuch as they to a large extent controlled the destinies of those who committed themselves to their care. A careful training must be acknowledged to be of the highest importance, as education became thereby the keystone to examination.

The position of the examining bodies was justly accounted as being quite as delicate and less enviable than that of teaching bodies, because their contact with the life and susceptibilities of students is of short duration, and because moreover the capabilities and resources of the student have become by the time he presents himself for examination almost a known quantity. The duties of the examining body are to endeavour by a process of general questioning, not always without a little reason, to ascertain if the examinee has so trained his mental faculties, as to have earned that qualification or licence necessary to enable him to pursue the profession for which he has been training. Turning to the much discussed question of the teaching staff becoming examining bodies, he pointed out it was for those interested to consider how far teachers could undertake such work without being influenced by bias. Examining bodies must, like Caesar's wife, be above suspicion. He held it must be admitted that teachers make the best examiners, because owing to their experience of the peculiarities of students they are most likely to foster that sympathy which should exist between them and the candidates. On the other hand, the fact should not be overlooked that in the event of the teachers sitting as examiners, in the course of time it would come about that their pupils would appear before them to obtain that qualification for which they had jointly laboured. He asked, Would not such an arrangement admit of collusion, or at any rate give rise to a suspicion of it?

In the discussion that followed Mr. Ward thought it unjust that a student who failed in one subject should be compelled when he next presented himself to again pass in the subjects in which he had been successful. He also suggested that the Minor and Major examinations should be merged, to be passed on two different occasions, the first part to be in writing and the second a practical one. He would also raise the standard of the Preliminary examination.

Mr. Morrison remarked that he had doubted the wisdom of the arrangement alluded to by the reader of the paper, and had there been a preponderance of successes on the part of students at Bloomsbury Square he would have objected to it, but such was not the case. In fact, the students at that institution had not been so successful as those taught elsewhere. He would prefer to be examined by a teacher than by a duffer. He did not agree with the suggestion as to the merging of the Minor and Major, but would like to see more subjects in the Preliminary, and have it more on the lines of the London Matriculation, though hardly so stiff.

Mr. Mallaband thought that to appoint professors at Bloomsbury Square as examiners would be unfair to students trained at other places.

Subsequently, Mr. Rhoden was thanked for his paper.

PLYMOUTH PHARMACEUTICAL ASSOCIATION.

The quarterly meeting, held at the Foresters' Hall, Plymouth, on Wednesday, the 10th inst., at 7.30 p.m., was a very representative one. Those present included C. J. Park (President), J. Maurice, R. F. Roper, A. D. Breeze, A. P. Kelly, J. G. Netting, Freeman W. Hunt, A. D. Davey, John D. Turney, R. Rendle, F. Maitland, W. H. Woods, J. Harvey Bailey (Treasurer), James Cocks (Hon. Sec.).

A meeting of the Trade Defence Section had previously been held at 7.15 p.m., to confirm the action of the committee re appointment of analyst and solicitor.

After the general business Mr. R. F. Roper introduced a discussion on "Matters of Trade Interest," dealing chiefly with prices and early closing, also alluding to Sir J. Lubbock's compulsory early closing Bill.

Mr. Kelly thought early closing ought to be made compulsory, and that chemists should be included in Sir J. Lubbock's Bill, also that local M.P.'s should be asked to support the same.

Mr. Rendle thought chemists should not supply articles after hours and on Sundays, as it frequently meant facilitating matters for stores who closed early.

Mr. Davey was afraid they were a bit at sea as to the true nature of the Bill, and that they should defer supporting it until better acquainted with its contents.

Mr. Park said the public seemed under the impression that chemists were always open for their convenience, and felt that by uniting the difficulty might be easily overcome; and as regards prices, since they had reached such a low ebb, he felt they were at the
bottom in that respect, as business would be practically unworkable if they went any lower.

Mr. Bailey asked if compulsory closing became general, how about emergency cases?

Mr. Hunt thought compulsion to close earlier would work all right, taking as a precedent banks. He also considered all B.P. medicines should be restricted to vending by chemists only.

Mr. Maitland thought some difficulty would arise in early closing in the three towns, owing to the geographical situation.

Mr. Turney felt the public ought to be more considered on Sundays.

Mr. Cocks proposed that the following resolution be sent to the Council of the Pharmaceutical Society:

"This meeting approves of chemists being included in Sir John Lobbick’s Compulsory Early Closing Bill, provided a clause be inserted for supplying medicines in cases of emergency." This was seconded by Mr. Kelly, and carried.

Mr. Roper replied to the various remarks, and a vote of thanks was proposed by Mr. Rendle, seconded by Mr. Woods, and carried unanimously, as was also one to the Chairman, proposed by Mr. Kelly, and seconded by Mr. Maitland.

---

Scottish Transactions.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

The annual general meeting of this Association was held on Thursday, 4th inst., at 9.15 p.m., and there was a good attendance, being the best during the session. Mr. W. L. Currie presided, and, after the adoption of the minutes, introduced the first part of the business, a report from the Committee appointed in council to draw up suggestions for a new Pharmacy Bill.

Report of Legislative Committee in Favour of a New Pharmacy Bill.—It is agreed: 1st. That the Pharmacy Acts require amending! 2nd. That all persons on the Register of Chemists and Druggists be members of the Pharmaceutical Society and eligible for election to Council in virtue of such registration! 3rd. That all open shops for the sale of poisons and dispensing of prescriptions be registered! 4th. That the registration of persons and shops be maintained by annual fees! 5th. That the term “person” shall include the individual members of a corporate body! 6th. That the Preliminary examination be passed before beginning the period of apprenticeship, and that a curriculum before the qualifying examination be enforced! 7th. That there be district representation on the Council! 8th. That the Pharmaceutical Society be empowered to exercise control over the conduct of its licensees, even to the removal of names from the Register!

The President having read the clauses, a discussion on the clause making it compulsory that the Preliminary examination, or an equivalent to it, be passed before apprenticeship begins, was entered upon. Fear were expressed that apprentices would be difficult to get under such conditions, but the report was ultimately approved of unanimously. In connection with this the President expressed a strong desire that in cases of civil prosecution, the employer should be liable for all fines.

The secretary afterwards read the following report of the Committee—Messrs. Boyd, Dunlop, and Lacing—appointed to consider the—

REVISION OF THE BRITISH PHARMACOPEIA OF 1885.
The Glasgow and West of Scotland Pharmaceutical Association desires first to thank the Medical Council and the Pharmacopeia Committee for their courtesy in inviting pharmacists generally to co-operate with them in producing a new Pharmacopeia which should be in advance of any similar production that has preceded it. We are fully aware that it will be a difficult and arduous work; and the difficulties should not be perceptible in the finished product, which ought to be on all points definite, decided, comprehensive, and brief.

Weights and Measures.—We are of opinion that (though the metric system of weights and measures must ere long be adopted to the exclusion of any other system) it would be injudicious to withdraw the present system at one fell sweep, as much from consideration of the derangement it might cause to prescriber and dispenser as to the pharmacist in manufacturing official preparations. Therefore we think equivalents in metric weights and volumes should be stated throughout the formulae for this edition.

Withdrawals.—As old generations of physicians pass away, many of the remedial agents they employ pass with them, new and more advanced types of physicians and medicines taking their places. It is unwise and unfair to the rising generation to retain remedial agents now comparatively seldom used and likely to be less used in the future, since their places are more than filled by agents of more virtue and activity. And, as the value of any drug lies as much in the intelligence wherewith it is administered as in its own qualities, a few agents well known by the physician—tried and proved—are more serviceable than many, of which a theoretical knowledge only can be acquired. Therefore the weeding out should rather err in being overdone than underdone, and a better knowledge of what is retained must result to the advantage of the Pharmacopeia, of the younger physicians, and students of medicine.

Proposed Omissions.

**Proposed Additions.**

- Aetanilidium. Dose up to 4 grains.
- Acid. hypophosphorosum. 30 per cent. $\text{HP}_2\text{O}_4\text{Sp. g.} 1:1307$. 1:22. Dose up to 2 minims.
- So with lithia, using carbonate, and potasium.
- Pil. phosphori compositae, containing iron, quinina, and nux vomica et strychniae.
- Pulv. cretes gummosae, for making mistura cretes—Prepared chalk... 1 part Powder of acasia 1. Powdered sugar... 1. Mix.
- Eucalyptus oil. morphine hypophosphite. Elixir in place of syrup. rhei et syr. senna.

**SUGGESTIONS AND MODIFICATIONS.**

Nothing should be taken from the Pharmacopeia of which the composition and mode of producing cannot be given.

Processes need not be given for the manufacture of chemicals which can only be produced on the manufacturing scale.

All tests given should be followed by a statement of the object of the reaction, positive or negative, indicating what they are to prove or disprove.

List of preparations into which a drug enters should be deleted.

*Acetum Scillae.*—Bulb to be cut small (not bruised) and acid. aect. dil., 1 in 6, should be used for this preparation.

*Glycerin preparations* (excepting glycerinum plumbi subsect. and glycerinum amyli) to be uniform—1 in 6 by volume.

*Mucilage of acacia* to be made with chloroform water.

*Oils (Fixed).*—Tests for purity to be given, and to detect impurities.

*Ointments,* where practicable, to be prepared by melting the base by a steam or water bath before adding the medicament.

*Gall and opium ointment* is improved by infusing the opium in the benzoated lard at a temperature just over its melting point, for an hour before adding the powdered galls.

**Iodide of Potassium Ointment**

*Take of—* Iodide of potassium 64 grains Hypophosphite of sodium 1 grain Glycerin 60 grains Benzoated lard 1 ounce Water 5 minims.

Triturate the iodide with the glycerin, add the lard, and lastly the hypophosphite of sodium dissolved in the water.

*Oleate of Mercury Ointment* (30 per cent.).

*Take of—* Red oxide of mercury 1 ounce Oleic acid 23 ounces White petroleum (paraffin molle albi) 14 ounce.

Add the oxide to the acid at the temperature of a steam bath, and after combination add the white paraffin. To be diluted with oleic acid or paraffin as an oleate or an ointment is required.

*Pill Excipiens.*—Aloes and myrrh: syrup 1 part, in place of treacle and glycerin, and pills 4 grains. Aloes and iron: confection of hips, colocyth. co. sp. ammon. aromat., 1 part to 20. Pil. plumby c. opio 1 in 8 of a mixture of 4 equal parts of P. acacia, glycerin, simple syrup. Pil. rhei co. simple syrup 1/2 for treacle and glycerin (4), and 4 grain pills.

*Syrupes* to have the sugar in the proportion of not more than 32 to 17 of fluid. Cane sugar always to be...
used. Syrups of iodide and phosphate of iron are improved by having 1 minims per ounce of hypophosphorous acid.

**Syrup of Squills—**

Take of——

Dissolve with a gentle heat.

**Suggestions.**

Tincture of opium to be prepared by the process of the old Edinburgh Pharmacopoeia.

Tincture of calums to be prepared with rectified spirit.

Acid Carbolic—Raise melting point to 38°C. or 40°C. give quantitative test. Vide U.S.P.

Acid Salicylic—Melting point 156°C.

Argenti Nitrata—has been prescribed in doses of 5 grains.

Emplastrum Belladonnae. To be made more consistent by lessening the amount of extract.

Morphinae Tartras for hypodermic solution.

**Desideratum.**—A condensed pocket edition of the Pharmacopoeia with flexible binding, containing only formulae and dose. Arranged under the head of the drug or chemical which gives the name to the article (as in Squire's "Companion"), for the use of the medical profession. Vide Pharmaceutical Journals for December 15, 1894, January 19, and March 2, 1895.

**Committee...**

THOMAS DUNLOP, PH.C., M.P.S.
ALEXANDER BOYD, A.P.S.
ALEXANDER LAING, A.P.S.

In the discussion a disposition to question some of the findings manifested itself. Of the formidable list of things to be withdrawn, several appeared to have advocates in favour of retaining. The preparation of ointments by the process of double decomposition found favour; a desire to increase the number of effervescent preparations found expression, but the battle royal was waged for and against the metric system of weights and measures. As the system to be adopted forthwith, it was supported by three independent voters (the Committee did not vote); as an alternative with the present system it had seven supporters, while a large majority favoured the present system and no other. Nevertheless, the report was sanctioned with unanimous consent, and the Committee thanked for its services. The treasurer, Mr. J. Anderson Russell, then intimated that the income for the session amounted to £24 2s., expenditure £14 8s. 11d., balance £9 14s. 1d., total balance £5 8s. 7d.

The secretary then read the following:—

**ANNUAL REPORT.**

Reflecting upon the events of the past year, the third of our existence as an Association, your Council considers that the session now being closed has surpassed previous sessions in hard, practical work, and has been remarkable in several ways. The great event of the session undoubtedly was the visit of the President of the Pharmaceutical Society, Mr. M. Cartegehe, in November last, which called forth the best meeting of pharmacists Glasgow has seen for many years. Nor was the address delivered on that occasion by Mr. Car- tedgehe transient in its effect. Vigorous plain-speaking without ambiguity is relished by "lang-helleded" Scots as most complimentary to them; and that distinguished the address throughout. It did more to let us know where we are and how we stand than any previous rhetorical effort has done; one of its effects being to produce the Committee on Legislation amongst your Council, whose report has just been handed in. The next important event of the session was the severe weather which prevailed throughout the earlier part of the year, and had a modifying influence on the attendances at our meetings, as the members who were not rendered hors de combat themselves had so much to do in ministering to the sick and afflicted that the business of the Association had to be carried on in the absence often of its most regular attenders. The opening address given by Dr. D. C. McVall presented a high ideal of the respective duties of physician and pharmacist, and was worthy of such a man. The absence of our President since the opening meeting was matter of general regret, but the pleasure of seeing him again amongst us, though towards the close of the session, is correspondingly great.

The bulk of the work done has been closely connected with matters pharmaceutical, and but for small attendances a considerable advance is observable in the subjects brought before the Association. Mearns, Laing, Boyd, Dunlop, and Brodie gave papers all bearing more or less on the Revision of the Pharmacopoeia; Mr. Lunnan, of Edinburgh, contributed valuable notes on the same important subject. All of these papers have again come under consideration by the Committee appointed to arrange the suggestions in their natural order, whose report is also now to hand. The Association is likewise indebted to Mr. Wm. Watson for notes on Parriah's syrup, some commercial samples of which he found to have too little lime for building purposes, and some in which the presence of iron could only be inferred. Mr. Blair, on Hospital Dressings, introduced an interesting subject which proved a good case, and was treated exceedingly well. Dr. Carswell and Dr. Bryoe gave lectures of deep interest to all who heard them, and last, but not least, Mr. Rutherford Hill added one more to the good accounts he has given us of things that everybody does not know.

The motion brought forward in June last by Mr. Russell, the discussion of which was adjourned, it has not been possible to adequately consider during the session, as the syllabus shows, but since it was duly seconded and appeared to your Council to embody important legislative suggestions, it has been taken in hand by the Committee appointed to draw up suggestions towards a new Pharmacy Bill, and adopted in the form submitted to the Association. Your Council thinks it unfortunate that business has to be carried on to such late hours that the meetings are not started early enough to allow the papers read to receive the
full amount of criticism which they deserve, and such as would give more life and liveliness to the meetings. It is also regretted that the younger members do not take a more prominent part in discussion; and an endeavour will be made in future sessions to obtain from them more active co-operation in arranging the syllabus.

In looking over the actual work done during the session, your Council is strongly of opinion that, if early closing could enable the Association to begin its meetings at an early hour, it possesses all the qualities essential to making it one of the best organisations in the country in connection with pharmacy. In conclusion, your Council has much pleasure in expressing its satisfaction with the presiding genius of Mr. John Foster during the temporary disablement of the President. Mr. Foster's urbanity and tact have been pleasingly experienced by the members and appreciated accordingly. The membership on the roll was 144.

The reports having been approved of,

Mr. W. L. Currie in retiring from office spoke strongly in favour of early closing, urging chemists to give their support and come under the jurisdiction of the Bill now in Parliament. He thought the late hours were shameful, and the public had been too well served by chemists for no good reason. He thanked members for their courtesy and kindness during the three years he had been in office, and hoped the Association would continue to flourish like a green bay tree. Mr. John McMillan moved, and Mr. T. Robinson seconded, that Mr. Currie be again elected President. It was warmly endorsed by all the members, and Mr. Currie was prevailed upon to continue President of the Association. Most of the former office bearers were re-elected, the changes being Mr. J. Anderson Russell, elected to fill the offices of secretary and treasurer, Mr. Innes, elected district secretary for the northwest, and Mr. Alexander Miller for the north-east, Mr. Maltman to the Council, and Mr. A. Laing, late secretary, vice-president. The third by-law was deleted, and the limit to three vice-presidents removed from the rules. The membership subscription to be paid by country members was left over for the Council to decide, and the business concluded.

\textit{Notices of Books.}

The new edition of this useful work gives ample indication of the care bestowed by the authors upon the work of incorporating information acquired since the last issue, three years ago. The extent to which new material has been added will be evident from the fact that the present edition contains fifty-seven pages more than the last. The continued introduction into medical use of various synthetic products has afforded occasion for part of the increase in the extent of the work, while the descriptions of the articles comprised in the recent addenda to the 'Pharmacopoeia Francaise' and the 'Pharmacopoea Germanica,' as well as those included in the unofficial forms of the British Pharmaceutical Conference, occupy a considerable part of the additional space. A special chapter is devoted to the curative agents now obtained from animal sources in the form of antitoxins, serums, lymphs, and the preparations derived from animal glands and tissues. Throughout the body of the work many points worthy of note have been collated also from the recently published pharmacopoeias of the United States, Italy, Switzerland, Denmark, and Japan.

In view of the forthcoming revision of the British Pharmacopoeia, the authors state that they have been for some time past engaged in investigating the claims of drugs and preparations to official recognition. With that object they give the results of an analysis of a very large number of recent prescriptions, which have been collected not only in various parts of the United Kingdom, but also from Australia, New Zealand, Canada, and India; and tables have been prepared showing the unofficial articles which are most frequently in demand, and the official articles which are now seldom prescribed. It is interesting to learn that from these statistics it may be deduced that the \textit{materia medica} of the Colonies is much the same as that of the mother country, so that it may be assumed the requirements of an Imperial Pharmacopoeia will not differ very widely from those now existing in this country.

A prominent feature of the 'Extra Pharmacopoeia' is the therapeutic information which some recent critics of the British Pharmacopoeia think would be a suitable addition to that work. No doubt it serves a useful purpose in the 'Extra Pharmacopoeia,' and largely contributes towards making that book more popular to medical men than the British Pharmacopoeia is said to be, or perhaps need be, since its special purpose as an assistance to prescribers would be sufficiently served if it secured uniformity in the medicinal preparations which they are in the habit of ordering in their prescriptions. So far as official preparations are concerned, it may be taken as certain that such a condition is now much more to be relied upon than it was formerly, when pharmacists were very often in the habit of making medicinal preparations according to private formulae, and paid little attention to the Pharmacopoeia. But in connection with this point it is curious to observe how proprietary and patented preparations with fancy names are taking their place in the 'Extra Pharmacopoeia' in much greater numbers. Whether that be merely the result of a desire to furnish information as to the nature of these articles, or whether it is to be understood as an indication that such articles are being prescribed by medical men on the strength of recommendatory advertisements, we do not pretend to determine, but it is clear that there is here a considerable danger that the uniformity in medical treatment which would result from pharmaceutical adherence to the directions of the Pharmacopoeia may be counteracted or largely interfered with. That has been the case to a very mischievous extent in the United States, and it is the interest now taken in this country in regard to the therapeutic
aspect of pharmacopoeial revision can be directed towards securing greater loyalty to the British Pharmacopoeia amongst prescribers as well as pharmacists, much good may be effected.

The introductory part of the 'Extra Pharmacopoeia' contains some suggestive remarks as to the changes to be introduced in the revision of the British Pharmacopoeia, and prominence is given to the desirability of adopting the metric system of weights and measures, in conformity with the practice of almost all other civilised countries.

Anatomisches Atlas der Pharmacognosie und Nahrungsmittelmakunde. By Dr. A. Tschirch and Dr. O. Obrestle. Parts 5 and 6. Price 1s. 6d. each, nett. (Williams and Norgate, London.)

The fifth part of this anatomical atlas includes the examination of pomegranate bark, verbascom flowers, saffron, turmeric, and pepper; the sixth treats of ginger, red sandal wood, brasili wood, figs, orris, and marshmallow root.

Each drug is dealt with in the exhaustive manner which has characterised all the preceding parts of the work. Under pomegranate bark is included the bark of the stem as well as that of the root, the commercial drug consisting principally of the former; from the reactions obtained by various reagents, the parenchyma of the primary bark and phloem is considered to be the seat of the alkaloid pelliterine. The anatomy of saffron is followed by and compared with that of calendula florets and safflower, and in addition, a useful table has been appended showing the action of various reagents on powdered saffron, which should prove of material service in the examination of the powdered drug. Verbascom flowers will probably be of less direct interest to the English pharmaceutical student, but the study of these flowers and of the hairs which clothe the filaments as well as those on the calyx and corolla is extremely instructive; the former contain a substance frequently crystallising in sphero-crystals, and probably, judging from its reactions, a sugar. In view of the use of turmeric as a colouring agent, its identification in the form of powder is important; this can, according to the author, be effected without difficulty.

Black pepper appears to have received special attention. The morphology of the flower, the structure of the floral axis, and the development and anatomy of the fruit, both mature and immature, are fully described. The tissues which are specially valuable as diagnostic characters are pointed out, and the distribution of the piperine, together with the reagents that are most useful in detecting it, receive a fair share of attention. The plate which illustrates the anatomy of this drug is, without doubt, the most complete and most beautiful that has ever been published, a result due mainly to the improvement in the ink used, to the unsatisfactory nature of which allusion was made some time ago in the columns of this Journal. In this respect the succeeding plates compare unfavourably with those of Part 5. Of special interest in Part 6, apart from the anatomy of the drugs, is the demonstration that the red gum resin or resin of red sandal wood is formed in the 'resinogenous' layer of the cell-wall it is therefore a true secretion, and not a product of metamorphosis of the membrane. The crystals of calcium oxalate in orris root are shown to have a similar origin, and this fact is regarded as supporting the assertion that secretions are usually formed in the membrane, and not in the protoplasm. On the other hand, the mucilage in marshmallow root, which, like the secretions alluded to, is no product of retrograde metamorphosis, is deposited directly on the cell-wall in the form of secondary thickening; it appears to act, principally, at least, as a water-reservoir, since it is comparatively seldom redissolved, and to belong to the class of true mucilages, as distinguished from cellulose-mucilages which yield the cellulose reaction with chlorindiodine and similar reagents. These remarks suffice to show how replete with interest this work is for all who make botanical anatomy the object of their study. It is, however, to be regretted that the scale of magnification is still omitted.

Feeding and Feeding of Children. By Thomas Dutton, M.D. Pp. 198. 2s. (Henry Kimpton and Hirschfeld Brothers, London.)

We have on several previous occasions taken the opportunity of favourably reviewing Dr. Dutton's semi-professional writings on account of their excellence, plain sense, and lucidity. The present book is no exception to its predecessors, and shows clearly enough that the author understands thoroughly the subject on which he writes, and has the ability of making his opinions clear to others. Every chapter in the book is interesting, and no particular mode of feeding children is puffed up at the expense of others, thus showing that the author takes a broad view of the subject, and is in no sense a faddist. Mothers and nurses will derive the greatest possible advantage from a perusal of this book, and will also learn this great lesson—Many diseases from which young children suffer are wholly due to improper food; and the remedy for troubles thus produced is to improve the diet, and not to annoy the child by cramming it with drugs.

This is another addition to the list of Annual Reports issued by several large metropolitan hospitals; we trust that the subsequent volumes of 'King's College Hospital Reports' will equal the present one in interest and value. The book opens with a historical sketch of King's College and King's College Hospital, furnished by the Dean of the Faculty of Medicine, Dr. John Curnow. This is followed by a number of papers written by the physicians, surgeons, and those in charge of special departments. These special articles occupy 140 pages of the book. The remaining 220 pages are occupied by the usual statistical accounts of the cases treated in the in-patient and the various out-patient departments, and are, therefore, more complete than hospital reports in
general. There is interesting information under the heading "Wha' Old King's Men are Doin'," which cannot fail to interest those who were educated in this hospital. The "dolngs" of King's College are reported in such detail that the names of those who attended the annual dinner are duly recorded, and the volume concludes with a report of the after-dinner speech of the Chairman.

VULCANITE WORK. By HARRY ROSE. Pp. 68, with numerous original illustrations. Price 2s. 6d. (J. P. Segg and Co., Regents Street, London.)

This little book is written to explain the best methods of working vulcanite so as to obtain in the highest degree strength combined with thinness and lightness. The author devotes considerable space to explaining how to use and the advantages of the steam swager, which cannot fail to be of use to those who prefer this method of working, but he seems to claim too much for it. On page 10 he writes: "By using the swager for this purpose (contour work) the trouble and time lost in obtaining a single die and counter is saved, and the result obtained is so superior to that done by stamping up in metal dies that the two operations will not admit of any comparison." Now a comparison of the two methods is sufficient to show that, other things being equal, no time is saved, although the ultimate finish produced by the swager is certainly superior.

About three pages of the book are taken up by a confusing description of how to make a cooked vulcanite plate as a matrix to mount the teeth on. The advantages claimed are such as can be far more easily and quickly obtained by the other methods in vogue which the author briefly describes. The book deals with many of the difficulties which the inexperienced are likely to encounter, but it contains nothing new for those who have received a proper training in dental mechanics.

Correspondence.

DEATH AND THE ATOMIC THEORY.

Sir,—I was vastly pleased to see you in last week's Journal sitting so complacently on Dr. MacWheeler and his microbe-death. In my opinion you gave the right-wheel to both. If you would do the same with the atomic theory when it is used as fact I would feel so much obliged—ever so much. The atomic theory is beautiful, for working with it leaves nothing to be desired; but, as a fact, I cannot see an atom of sense in it. The very meaning of the word—solution—massacres it; leaves it not a leg to stand on. It dissolves, and you might dissipate it with a retort. Let it be dissipated.

Glasgow.

ALEX. LAING.

THE COUNCIL COUNCIL AND THEIR DISPENSERS.

Sir,—The circumstances under which the maximum salary of the Council's dispensers was reduced are these. About the year 1892 the Asylums' Committee decided to revise the salaries, emoluments, leave of absence, etc., of their officials, the result being that in nearly every case the salary was reduced and the emoluments abolished. This did not, however, apply to those who were at the time receiving the higher remuneration, but preventing any further advance. Those who entered the service after that date, or being in and not having reached the maximum, were bound by the new rules. Thus now all the dispensers commence at £160, increasing to £120, notwithstanding the fact that the duties have been increased by enlarging the establishments, opening of photographic studios, etc. This remuneration, as you justly remark, "cannot be regarded as a proper amount for educated and skilled dispensers." For, to quote the phrase so largely used by the Council themselves, can it be deemed to be "the rate of wages considered fair in the trade." I am informed on good authority that an application for increase was made some little time ago and was met with a prompt refusal, and the assurance that if the dispensers' positions were vacant they could obtain others to do the duties for less money.

VERBATIM.

THE DETERMINATION OF ACONEITINE.

Sir,—Is it not a little premature to attempt the exact determination of aconitine in the mixed alkaloidal product obtained from the usual galenical preparations of the drug? Mr. Unney, it is true, limits himself to Aconitum napellus, but even in that case it would be unsafe to assume that the acetic acid obtained by hydrolysis represented accurately the amount of crystallizable nap-aconitine contained in the sample. Wright and Baskett showed that A. napellus roots contained a small percentage of Fer-aconitine in addition to aconitine and certain amorphous substances, which were probably products of chemical treatment.

Moreover, I observed in 1878 ("Year-Book," p. 506), that all the alkaloidal bodies, whether crystalline or not, which I had isolated from A. napellus and A. ferrox gave off when heated destructively "acid vapours of the same odour as pyroglucine acid." It is probable, therefore, that Fer-aconitine contains in its molecule the acetyl component; to say nothing of the amorphous bodies which form such a large proportion of the total alkaloids. I used not to expect to get more than one-third of the crystalline variety.

It would obviously be most unsafe to run the risk of confounding substances differing so markedly both in degree and kind of activity. Let us then wait for fuller information, and meanwhile be content with noting crystalline form, the action of well-known reagents, and when possible the results of physiological tests.

As regards the method of determination proposed, I fail to see that the aconite produced by the hydrolysis is allowed for in the calculation. Being salifiable it would of course influence to some extent the titration. I regret that I have not at present access to my books and papers and have therefore to rely mainly on memory.

THOMAS H. GROVER.

Answers to Correspondents.

[Answers to queries, which are likely to prove of general interest, will be found under the heading NOTICES AND QUERIES.]

S. Frazier.—Your letter will be forwarded to the persons responsible in the matter, but there does not appear to be anything amis more serious than two slight printer's errors—the introduction of an unnecessary comma, and the substitution of "11" for "4".

W. A. MANNINGS.—We cannot undertake to express any opinion upon the preparation.

COMMUNICATIONS received from Muck, Brathwaites, Brown, Cockes, Gerrard, Jones, Hawthorne, Holloway, Lyon, Martindale, Robbins, Schwetzke, Umney.
Notes.

THE REVOLUTIONARY VALUE OF NEW ELEMENTS.—The National Observer, commenting on what it describes as a threatened glut of new elements, remarks that there can be no doubt of the revolutionary value of the new elements, argon and helium. New elements are by no means rare finds, but such elements as samarium or yttrium fall into line with other rare finds and alter the general fabric of theoretical chemistry not a jot. Argon and helium, however, are of a different texture altogether, and probably herald a great period of scientific reconstruction, whilst they make many of the dreams of the theoretical chemist, that had grown familiar and faint, bright and hopeful once more. "One asks: 'Is this at last the way? The transmutation of the metallic elements—the Discovery of the Philosopher's Stone they called it—was the mother idea of chemistry. Modern chemist is only old alchemist grown wiser by millions of experiments. No chemist to-day will admit that the transmutation of these basal substances is impossible."

NOVEL APPEND TO THE BALANCE.—For enabling workers with the balance to read the position of the pointer more exactly and readily, resot is often had to the device of fixing a magnifying lens before the divided scale. Another simple contrivance is suggested by W. H. F. Kuhlmann (Zeits. für Instrument.), in which the scale is reversed so as to face a concave cylindrical mirror attached to the column supporting the balance. The pointer is made finer at the end than usual, and moves between the scale and the mirror in which a magnified image of the pointer and scale appears.

STARVATION AND THE ACTION OF DRUGS.—The results of previous observers who have noticed that starvation affects the action of drugs has been confirmed in certain cases by Thomas Jordan (Journ. f. d. Med. Wiss.). Dogs were experimented on that had been fasting from three to twelve days, and control experiments were performed upon dogs of a similar kind. It was found that both the minimal dose producing any effect and the minimum fatal dose were less in the starved dogs than in the others, whilst the same dose killed the former sooner than those that were not fasting.

THE S. M. BURROUGHS' MEMORIAL.—We are asked to announce that the Council of the Chemists' Assistants' Association has opened a subscription list in connection with the above memorial, and that any contributions from one shilling upwards will be thankfully received by the Secretary, Mr. H. H. Robins, at 103, Great Russell Street, W.C.

POISONING BY ANTITOXIN.—The New York papers report the death of a girl of seventeen, after the injection of two and a half fluid drachms of Behring's antitoxin lymph. It is related that the girl was suffering from a slight attack of diphtheria, and died eight minutes after the injection of the fluid, having previously been violently convulsed.

Hemp Drugs Commission.—This Commission has declined to recommend the prohibition of the consumption of hemp drugs, but suggests a policy of restriction and control. The Governor-General also, having considered the matter in council, is of opinion that the Government should control the consumption and harmful use of hemp drugs, by making them as expensive as possible without driving people to resort to more noxious intoxicants than hemp.

EXHIBITION OF ECONOMIC PLANTS.—We are asked to announce that an exhibition of medicinal and other useful plants will be held at the Botanical and Zoological Garden, the Hague, Holland, from July 8 to 16 next. The five classes will include (1) living medicinal plants; (2), other useful plants; (3), drugs etc.; (4), vegetable products generally; and (5), books and instruments employed in the study of economic plants. Diplomas and medals will be awarded in each class, and particulars as to admission, etc., may be obtained of Dr. M. Geeschoff, Lann van Meerdervoort, No. 97, à Le Haye, Holland. The exhibition will be held simultaneously with the general reunion of the Société Néerlandaise de Pharmacie, which also takes place at the Hague.

DEATH OF DANA THE GEOLOGIST.—It is reported from Newhaven, Connecticut, that Professor James Dwight Dana, the eminent mineralogist and geologist, has died of heart failure. He had been Professor of Natural History and Geology at Yale College since 1855, and was a fellow of the Royal Society, London, as well as member of the French Academy, and other scientific bodies in Europe.

BOGUS GLUTEN FLOURS.—According to Modern Medicine a great number of bogus gluten flours are now being extensively sold in the United States. One sample examined was three-fourths starch yielding 0.715 Gm. for each gramme of flour. Occasionally ordinary "seconds" flour is sold as gluten flour, at a correspondingly advanced price, and ordinary bread can be made from most of the brands on the market.

ROYAL SOCIETY's TRANSACTIONS.—In reference to a contemplated alteration in the form of the Royal Society's 'Transactions,' Mr. C. Tomlinson, in a letter to the Times, suggests the advisability of dropping the term "philosophical," by which the publication has hitherto been distinguished, and he supports the suggestion by quoting the sarcastic remark of Hegel that "England is a country where the thermometer and barometer are called philosophical instruments."
DEATH OF LOTAR VON MEYER.—The distinguished author of ‘The Modern Theories of Chemistry’ has died at the age of sixty-five. He was Professor of Chemistry at the University of Tubingen, and had devoted his attention chiefly to the study of physiological and theoretical chemistry.

THE SUPPLY OF ANTI-TOXIC SERUM.—At the annual meeting of the Berliner Chemischen Fabrik auf Actien, it was stated that the number of horses now kept for preparing anti-toxic serum was 170, capable of supplying about 200 litres of the product per month.

THE EMPRESS FREDERICK AT SAN REMO.—Mr. Frank R. Squire, of San Remo, has recently received a very handsome scarf-pin of “diamonds and sapphires” from Her Majesty the Empress Frederick, which Her Majesty describes “as a small token of her gratitude for all the help and kindness shown during the stay of Their Majesties at San Remo.” Mr. Squire had already received the appointment of “German Court Chemist,” and is also gazetted chemist to His Royal Highness the Prince of Wales.

NATURFORSCHER VEREINAMMLUNG.—Apotheker S. Muham (Moldingerlées, 2 o) and Apotheker C. Pffaff (Sandstrasse, 16) announce that by arrangement with the managers of the 67th meeting of Naturalists and Physicians, to be held in Lubeck from September 16 to 21 next, they have undertaken to prepare for the sittings of the Section of Pharmacy and Pharmacognosy No. 53, to participate in which they invite all representatives of the craft. They also request that notice of papers or communications of any kind to be brought forward at the meeting may be sent in at an early date before the end of May, so that they may be mentioned in the invitations which will be sent out at the beginning of June.

ANNUAL DINNER OF THE PHARMACUTICAL SOCIETY.—We are desired to state that the full list of stewards in connection with the Annual Dinner on May 21 next, will be published in next week’s Journal. Gentlemen who desire to act as stewards should therefore intimate the fact to the Secretary, Mr. Richard Bremridge, 17, Bloomsbury Square, W.C., forthwith.

Miscellaneous News.

[Readers are invited to send local information of pharmaceutical interest. When newspapers are sent the paragraphs to be noted should be plainly marked, whilst cuttings should be verified by the addition of source and date.]

MORE INTERESTING MEDICAL DISCOVERIES.—Several interesting medical discoveries have recently been made in Vienna, and announced at meetings of the Society of Physicians. Professor Wagner von Jarregg, who is in charge of the department in the University devoted to mental diseases, was induced by the improvement that always follows upon an infectious disease in cases of insanity, especially if it be accompanied with high fever, to bring about that condition artificially by means of inoculations with Koch’s tuberculin. He now claims that though after each injection the decidedly favourable symptoms soon disappeared, there was such a steady clearing of the confused sensorium as to encourage him to continue the experiments. It was mentioned by Professor Albert, in the course of a discussion that ensued, that transfusion of blood and subsequent high fever had caused astonishing changes in the mental condition of one of his patients, whose pronounced melancholia disappeared, as though by magic, after the fever had subsided. He, too, anticipated good results from the artificial production of high fever in persons mentally deranged. Dr. Riehl, a lecturer at the Vienna University, has also made a curious discovery. A man was recently brought into his ward suffering from blisters and swellings on the hands, as well as on one eye, which he had touched with a swollen hand. The man was a gardener, and he attributed the blisters to a plant called Prunus cerasus, of the Experimen family. The experiment was repeated, and it was found that the tiny hairs on the leaf and stalks irritated the skin, and gave rise to swellings and inflammation. Dr. Riehl succeeded in extracting the poison, which the plant apparently contains for its own protection, and by means of injections with it claims to have healed more than one obstinate skin disease. His experiments are not yet completed, but they promise good results. Finally, Professor Neumann has described the case of a child four months old, who had reddish serpentine stripes under the skin of the arm. These, he found, were caused by the eggs of a small caterpillar having got into the pores of the skin. The tiny worm from one of them had crawled about, and so caused the red marks, which disappeared after it had been confined to one spot and extracted.—Booming Standard.

LONDON HOSPITAL MEDICAL COLLEGE.—A stained glass window containing the cost of arms or crests of past or consulting members of the staff of the London Hospital, has just been erected in the Library of the London Hospital Medical College. It has long been desired to perpetuate in some manner the names of those who worked and taught for many years both in the Hospital and College, and it was recently decided to adopt this form of doing so. The window just erected contains thirty-two shields on which are displayed the armorial bearings of past or consulting members of the Staff, including those of Dr. John Andrew, the first Physician, and Mr. John Harrison, the first Surgeon appointed in 1740. There are also the coats of arms of Sir William Blizard, Sir Andrew Clark, and Messrs. Richard Clement Headington, John Goldyer Andrews, James Luke, Thomas Blizard Curling, and Jonathan Hutchinson, all at one time or another Presidents of the Royal Colleges of Physicians or Surgeons, as well as other distinguished members of the medical profession who were on the staff of the London Hospital. It is hoped in time to add the armorial bearings of many others whose descendants at the moment have not been traced, and any information with reference to former members of the staff whose names do not appear in the present window will be gladly received by the Warden of the College, who will be pleased to show the window to all who may be interested.

SALE OF DEFICIENT LIQUOR IODI.—At the North London Police Court, on April 11, William Felton, chemist, of 255, Balls Pond Road, Islington, was
charged before Mr. Marsham, at the instance of the vestry of Islington, with having sold liquor lodi which contained 36° per cent. of iodine and 37° per cent. of potassium iodide, and was therefore not of the nature, substance and quality demanded.—Mr. Hoare prosecuted, and explained that this was a test case. The medical officer of health for the parish wrote out the prescription for six ounces of the preparation, and nearly disclosed the deficiencies stated.—Mr. C. V. Young said, in defence, that the defendant would plead guilty, but the weakness of the drug was accidental. It was a most volatile drug, and as it had been made some time and was seldom asked for its strength had evaporated. Its place had been taken by a tincture as the Excipient, and although it was present appeared as a drug in the British Pharmacopoeia it would in the next edition probably be omitted.—Mr. Felton explained that to prepare the liquor-lodi properly it would take from two to three hours. The messenger said that he was in a hurry, and to oblige him he delivered him 44° of opium in China. It appears that and filled the bottle up with another preparation. The decreased strength would have no material effect on the drug, which was meant for outward application only, while the profit which might have been made had any dishonest intention was one-eighth of a per cent. Marsham imposed a fine of 20s., with 12s. 6d. costs.

Poisoned in the Pulpit.—A peculiar case of poisoning is reported from Mobile, Alabama, U.S.A. The Rev. Mr. Jessop, a Baptist minister, while in the midst of a discourse fell to the floor, and died in a few minutes. The unfortunate clergyman had placed in one of his pockets some pieces of bread poisoned with strychnine, for the purpose of destroying the English sparrows which infested his garden in great numbers, and in another pocket he had placed a few lumps of sugar, with which he was in the habit of clearing his throat during his sermon. He appears to have placed his hand in the wrong pocket, and swallowed the poison before he discovered his mistake.

The Opium Commission.—The British Medical Journal says: The text of the Report of the Opium Commission is not likely to be published until the table of both Houses as soon as possible. The Commissioners state that the abuse of opium as a drug and for smoking purposes is much less in extent than has been stated by some, and that the people of India do not make such an intemperate use of the narcotic as is alleged. India only sends to China about one-fifth of what that country uses, and that the rest is not entirely homegrown, but is imported from other countries, notably from Persia. In view of all the facts of the case, the Commissioners are not in favour of prohibiting either the growth of the poppy or the manufacture or sale of opium in British India. While, however, they are opposed to prohibition, they make certain suggestions in regard to the regulation and restriction of the traffic, and recommend that the decision of the Indian Government to put a stop to the smoking of opium on licensed premises be put in force. Although, however, the non-medical use of the drug for pleasurable purposes appears to merge so into its medicinal use for the mitigation of suffering and the prevention of disease that it would be extremely difficult—indeed, impossible—to interfere with the one purpose without inflicting great hardships on those who resort to it only as a solace, and who find in it their one resource in the various ailments which are so common in damp and malarious districts. The investigations of the Commissioners make it clear that the habit of opium-smoking in India is quite a subordinate affair compared with that of opium-eating, and that it is not the former, but the latter, which is the mode of the morphine habit, for the material absorbed consists not of morphine but of the products of its destructive distillation. It is, in fact, a habit or a vice of comparatively few, and is mostly confined to the towns, and a good deal of evidence went to show that its apparent evil effects were not due so much to the habit as to circumstances amid which it was practised and to the character of the people who indulged in it. It was clear that the habits of the opium dens included a number of idle, dissipated, and vicious persons, and that the habit of opium-smoking was often resorted to by sufferers from fever and, it might be, other kinds of suffering, and it became obvious to the Commissioners, and those who followed the evidence, that the diseases prevalent among opium smokers were by no means always due to the habit. The report is against enforcing any radical change in a custom which, in regard to opium-eating, is centuries and a perusal of the addendum written by one of the native commissioners makes it clear that an alcohol-drinking people can but with evil grace protest against a habit for which there is so much more excuse, and which produces so much less evil result than would follow what many consider the alternative—namely, the spread of alcohol or ganja.

A craving for Chlorodyne.—At the recent Plymouth Quarter Sessions, Albert Tulidgie, 49, draper, and Patience Tulidgie, 58, brother and sister, on bail, were charged with obtaining by false pretences from Mr. James Maurice, chemist, one bottle of chlorodyne, of the value of 2s. 9d., with intent to defraud, on February 3.—Acquitted pleaded guilty.—Mr. Moleworth St. Aubyn, who appeared for the defence, said it was almost the saddest case within his experience. Up to the present time the prisoners had not been in the habit of drinking chlorodyne, but having been told that the habit of drinking chlorodyne had induced them to commit the offence with which they were charged.—Mr. Symons, who appeared to prosecute, said he did not wish to press the charge. Replying to the Recorder, the Chief Constable said the prisoners were old residents in Plymouth and they may have obtained the chlorodyne for the use of a highly respectable family.—Dr. Wolfestan, replying to the Recorder, said it was very seldom that persons gave up taking morphine, and when once they had contracted the habit, prevention was the only cure. The Recorder remarked that if anything would induce the prisoners to break off, this act of taking chlorodyne it was their present position.—The Chief Constable having intimated that the prisoners would be cared for by their relatives, they were liberated on their own recognisances.

Dangers of Sublimate in Tablets.—On April 14, as the Western Railway express arrived at the Vienna Station, a young man alighted from a carriage and was going along the platform when he fell fast a glass cylinder, which was found to be filled with what appeared to be red buns. On examination, however, by a chemist it was discovered that the elaborately hand-crafted letters were composed of corrosive sublimate, and that each contained sufficient to cause the death of ten persons. It is believed that the young man who dropped this dangerous case of poisons came from Paris. He was not arrested at the time,
but the police are said to be diligently searching for him.

ACCIDENT IN AN ALUM VAT.—On Saturday, April 13, at Overton, Essexham, Mr. Churton investigated the circumstances connected with the death of M. Joseph René Philpin, aged 81 years. A witness named Edward Owen, an employed at the Australian Alum Works, Runcomb, deposed that at 11.45 on Thursday, March 26, and M. Philpin were draining off a vat of sulphate of alumina, the temperature of which was 186°. The vat was over 4 feet deep. M. Philpin, wishing to bend a pipe, used a stick which was scarcely fit to bear a kettle. Witness was descending some steps to fetch an iron bar when he heard a splash. He ran back and found that the manager had been precipitated into the hot liquor through the breaking of the stick. He was promptly extricated, but his injuries were fearful, and he expired at three o'clock on Friday morning, which was his birthday. The drawing of the vat was not the duty of the manager, and witness would not have used a stick to assist the manager. The latter was considered that to try to raise a heavy weight with a stick was most imprudent. Mr. Linaker, solicitor, representing the bereaved family, said the deceased had admitted that he alone was to blame for the accident. A verdict of accidental death was returned.

DRUGS FOR IRISH PAUPERS.—The fraudulent traffic in drugs for Irish paupers, which has been carried on for the last twenty years with the connivance of the Local Government Board for Ireland, is further developing. Emboldened by impunity and by the tacit acquiescence of the Government's department whose duty it is to protect the public and the ratespayers, traders in adulterated physics, and decrepit medicated materia medica are becoming more audacious, while the guardians, sometimes bewildered and sometimes venal, pay, out of the ratespayers' pocket, monstrous prices for pharmaceutically rubbish, which, when it is not pernicious, is commonly useless. The newest departure in the drug jobbery market is the giving of drug contracts to traders who are neither apothecaries, pharmacists, nor druggists. In one union the dispensary doctor has been made contractor for his own drugs, and for those of two of the neighbouring counties. Whether or not such an arrangement is judicious, it can at least be said that the contractor is supposed to be a capable judge of the quality and price of the articles which he contracts to supply. The Carrickmacross Guardians have, he said, been this record, for they have had aside every chemist or druggist who tendered, and have given the contract for drugs to the keeper of an ordinary unquestionable public-house named Daly. Will the Local Government Board stand this? It seems probable: the department could not remonstrate without offending Mr. Daly's relatives and friends, who might get some M.P. to assail the Government's department. Will the Local Government Board in the House of Commons. As the sick pauper has no friends in our or out of the House of Commons, it is manifestly wise diplomacy for the Local Government Board to keep on Mr. Daly's side. Besides, the precedent will be useful, for it will admit of an indefinite extension of the present plan to the guardians' friend. It will be easy then to give the contract for paupers' boots to a popular ironmonger, or to get the union flour from the proprietor of the local newspaper.—Medical Press and Circular.

ABUSE OF POISONED IN GLASS FACTORIES.—An exchange relates a peculiar case of arsenic poisoning of the manager of a large firm bottle works in this state. He had been a flint worker and risen to the position of manager by industry and as a result of his superior intelligence. Truth not particularly robust, yet he had a good constitution, and, as he was not given to dissipation and his habits were regular, he enjoyed very good health. But not long after he became manager of the works, his health began to fail. He grew thin and emaciated, lost energy, had no appetite, and finally had to drop his work at the factory, and not long afterwards died. His case was a puzzle to the physicians, but as no post-mortem examination was held the puzzle was not solved, but the solution came later. The manager who succeeded this one, and who was a man of exceptional health and strength like his predecessor, began to fall in health not long after he took charge, and his case was very similar to the one which had proved fatal. The physicians were again puzzled, but in applying blister to the patient's chest the presence of arsenic was discovered, which gave the secret of the case. The patient was treated for arsenic poisoning and recovered. He had enough arsenic in his system to kill a dozen men if administered in regular doses. In these cases the poisoning was slow and insidious. The manager had a small room where he kept his tools, books and chemicals, and among the latter arsenic. As he spent considerable time in this room, the breathing of the arsenic fumes had gradually impregnated his system with the poison, and this was the cause of his gradual failing in health. After the recovery of the manager the arsenic was kept in a room by itself and he enjoyed good health as before.

These cases go to show what great care should be exercised in the use of arsenic in glass factories, especially in flint works where it is used in consider able quantities. It should be stored in a cool place, where there is no one to work, and should be handled carefully in making up the batch. With careful use it should not be injurious to the batch mixer, unless his system is especially susceptible to it, as some persons are affected by it in much greater degree than others. Managers and batch mixers should not forget that they are handling a very poisonous substance, and should take proper precautions accordingly.—American Manufacturer.

Technical Notes.

DETERMINATION OF SUGAR.—L. Grünhut has suggested a method with the view of decreasing the possibility of error in determining sugar with alkaline copper solution. As is well known, cuprous oxide is again difficult, completely oxidised, the result is consequently often too low. This is overcome by collecting the cuprous oxide on a tarred ashless filter and placing in a glass tube, and after burning off all organic matter by strongly heating in a current of dry hydrogen, and then weighed.—Public Health.

PROTECTION OF IRON AND STEEL FROM RUST.—Professor Calvert, according to Agriculture, has arrived at the conclusion that carbonates of potash and soda possess the same property of protecting iron and steel from rust as do those alkalies in a caustic state. Thus it is found that if an iron blade is immersed in a solution of either of the above carbonates, it exercises so protective an action that that portion of the iron exposed to the atmosphere air does not oxidise, even after so extended a period as two years. Sea water, to which the carbonates in suitable proportions have been added, is said to produce similar results.
DETERMINATION OF CHLORINE. — As Mohr's method of determining chlorine, when applied to urine, gives too high results, owing to silver chromate being somewhat soluble in it, E. Bödtker has devised a method which he claims, though rather more complicated, gives accurate results. The reverse of Mohr's method is strongly acidified by diluting the urine with nitric acid, adds an excess of standard solution of silver, and as only silver chloride is precipitated in the presence of nitric acid, he filters and carefully neutralizes the filtrate with a weak alkali, and then titrates the excess of silver by standard solution of sodium chloride.—Public Health.

PREPARATION OF PURE TITANIUM. M. Henri Molissanhas recently succeeded in preparing titanium in a nearly pure state. This has hitherto been a matter of great difficulty. When the metal is prepared by the reaction of sodium or potassium on a haloid salt of titanium, the latter is always greatly contaminated, either by nitrogen—for which it has a certain affinity—forming a complex compound with the sodium, potassium, or oxygen. The nitride of titanium is easily prepared in the electric furnace, in the form of a bronze-coloured mass, by strongly heating titanous acid in a carbon boat, using a current of 300 to 350 amperes at 70 volts. When this nitride is heated, a mixture of titanium is formed. The temperature at which this nitride decomposes is exceedingly high; but by means of a current of 1200 amperes at 70 volts M. Molissan has succeeded in obtaining a carbide of titanium free from nitrogen, using for the purpose a mixture of titanous acid and carbon. By repeating the operation in a crucible, the carbon not being in excess, an ingot is obtained of which the upper portion is an alloy of titanium and the carbide of the metal. By mixing this with a fresh supply of titanous acid and reheating again in the furnace with a current of 2000 amperes at 80 volts, a purification of the metal is effected, and a sample of titanium containing only about 2 per cent. of carbon is obtained. In this condition it is found to have a brilliant white fracture, and is said to scratch rock crystal easily. It is, however, brittle, and can easily be reduced to powder, but is the most refractory substance yet reduced by means of the electric furnace.—Electrical Engineer.

ARTIFICIAL RUBBER. — An artificial rubber of more or less strength may be obtained by dissolving four parts of nitro-cellulose in seven parts of bromo-nitro- toluol. Upon varying the proportion of the nitro-cellulose there may be obtained a material possessing elastic properties and much resembling indiarubber, and even gutta-percha. Nitro-cumol and its homologues may, if desired, be used instead of bromo-nitro-toluol. According to invention, another artificial rubber has lately been discovered by E. Despres, of Paris. Gutta-percha, in the form of sheet, is taken and covered on one or both sides with a close-meshed fabric—even wire gauze will serve for some purposes—and the whole is gluesomated by pressure under heat. Sawdust, rice dust, and other suitable moisture-moisture may, if understood, be incorporated with the gutta-percha.

DYE PRODUCTS BY ELECTROLYSIS.—Naphthazarin and intermediate products related to it, may now be prepared, says the Electrical Review, by means of electrolysis; and the fact is very suggestive. If one, why not all? Or, at least a great many of those numerous substances which are now used in the important industry of dyeing? To prepare naphthazarin a hot sulphuric acid solution of 1:1—dinitro-naphthalene is submitted to the action of an electric current. 1 kilogramme of the mother substance is dissolved in 20 kilogrammes of acid, and the temperature is carried to 130° C., the vessel in which the operation is performed being provided with a porous diaphragm. The cathode is immersed in the hot solution, and the anode in sulphuric acid, the diaphragm separating both. A current of 15 amperes per square diameter is passed through the containing vessel until the mother substance has been completely converted into the intermediate product. The "melt" is then allowed to cool, and is worked up into a salable product. The process belongs to the Basleche Anilin and Soda Fabrik, a company that has probably paid more fees to the Patent Office than any contemporary corporation.

Patent Office Business.

APPLICATIONS FOR PATENTS. Where complete Specification accompanies Application, an asterisk is suffixed.

No. 6680.—Improved metal bottle-necks. April 1, 1895.
No. 6707.—Improved focussing appliance for photographic cameras. April 8, 1895.
No. 6725.—The production of nitric acid (HNO₃) and the nitrates of soda, of potash, and of lime. April 2, 1895.
No. 6899.—Improvements in an apparatus for drawing-off liquids. April 8, 1895.
No. 6898.—An embrocation for the cure or alleviation of gout, rheumatism, neuralgia, and other ailments. April 8, 1895.
No. 6896.—A new or improved medicinal compound. April 8, 1895.
No. 6903.—Indicator for showing kind of sensitive plate or film placed in photographic dark slide, and whether same is "exposed" or not. April 4, 1895.
No. 6927.—An improved apparatus for tilting and emptying liquid measures. April 4, 1895.
No. 7029.—A new or improved method of hermetically closing jars, bottles, and other vessels for the better preservation of their contents. April 5, 1895.
No. 7050.—Improvements in liquid funnels. April 5, 1895.
No. 7104.—Improvements in the production of photographs in natural colours. April 8, 1895.

PATENTS PUBLISHED APRIL 13TH.

Extracting gold and silver from ores (Nicholas, J.).—Refractory or other ores are treated with a solution of oxalic acid before treatment by the amalgamation, cyanide, chlorine, or other methods commonly used, or the oxalide may be used in conjunction with a hydriochlorite to extract the gold by a single treatment. The inventor prefers to saturate the powdered ore with oxalate solution, after which a solution of calcium hydriochlorite is allowed to percolate into and digest with it for an hour. The liquid is drawn off, and the gold is precipitated with stannous chloride. The silver chloride in the residual ore is removed by any suitable solvent. No. 6590 of 1894.

Ventilating and sterilising the air of hospitals (Brophy, M. M.).—The windows are kept permanently closed, and the walls, etc., of the wards are made of such material as will withstand a temperature of 700° or 800° F. without burning. The air is drawn from each chamber into the flue of a furnace, and is thus sterilised before escaping, and

* From the Illustrated Official Journal (Patents).
arrangements are made for introducing highly-heated air into the bottle to sterilise the fittings from time to time.

No. 7313 of 1894.

**Bottle for aerated and other liquids** (Kishby, W.).—The bottle is provided with a hemispherical mouth, in which fits a spherical stopper provided with a handle and hinged to a strap fixed to the bottle neck. The stopper is closed, but when it is turned into one position, a curved passage through it is brought opposite the bottle mouth, and the contents are discharged from a spout on the stopper. No. 7565 of 1894.

**Cellulose acetate** (Gross, G. F., and Bevan, E. J.).—Cellulose hydrate prepared as described in Patent No. 8700 of 1894, is mixed with a stated proportion of a small quantity of acetic acid, and dissolved and dried in vacuo to 110° C. It is then powdered and mixed in successive small quantities with a definite quantity of acetyl chloride, the temperature being maintained below 90° C. The zinc salts are removed by washing, and the residue is pressed and dried and dissolved in chloroform to free 2% from any unchanged cellulose. The inventors point out that this material is non-explosive, and that its chlorof orm solution serves as a substitute for collodion for surgical and other uses, as a varnish, and for mixing with oils for varnishing, etc. No. 8676 of 1894.

**Disinfectant or antiseptic** (Walker, J. T. A.).—The invention comprises the use of a solution of thymol in glycerin or glycerine and water in stated proportions, for use in the manufacture of soap, tooth powders, antiseptic washes, etc. The solution may be mixed with carbonate or sulphate of lime or other solid, to form a powder. No. 7296 of 1894.

**Making nitric and hydrochloric acids** (Campbell, A., and Walker, A.).—Relates to the use of acid sulphate of potash or soda, such as is obtained in the ordinary manufacture of nitric acid or by the inventors’ method of adding dilute sulphuric acid to the mixed sulphuric and nitric acids obtained in various operations, to “salt cake,” and evaporating at about 300° F. For making nitric acid, the acid sulphate is ground up with nitrate of soda or potash, and heated to about 460° to 450° F. The mixture is fed into the “still” by a hopper and screw, and the acid evolved is suitably condensed. Hydrochloric acid is similarly manufactured from common salt, the temperature used being from 600° to 700° F. No. 7875 of 1894.

**Alloys** (Vautin, C. T. J.).—Alloys of tin with sodium, potassium, lithium, calcium, barium, and strontium are obtained by electrolysis of a fused salt of the alkali or alkaline earth metals in an apparatus having a cathode of tin. No. 8078 of 1894.

**Sterilising milk, etc.** (Zweibohmer, F.).—The milk, etc., is placed in a vessel whose loosely-fitting cover is supplied with a liquid seal consisting of dilute glycerine. Any air admitted as well as the contents of the vessel is drawn down and thus passes through the glycerine, and is “to a large extent cleared of germs.” The contents of the vessel are sterilised by placing it for the required time in a vessel of boiling water. The vessel is fitted with a discharging tap and with an agitator for stirring, should the contents require it. No. 7867 of 1894.

**Poisoning Cases and Inquests.**

**Carbolic Acid.**—William Sterin, aged 46, died on Tuesday, April 9, in the Borough Hospital, Birkenhead, from the effects of carbolic acid, self-administered.

**Chlorodyne.**—William Bepert, aged 36, died on Friday, April 5, on board H.M.S. Dreadnought at Devonport, from the effects of an overdose of chlorodyne, self-administered. Verdict: “Decesed died from an accidental overdose of chlorodyne.”

**Osmotic Pouch.**—Frederick Charles Hargreaves, about 2 years old, died on Thursday, April 11, in the Southern Hospital, Liverpool, from the effects of osmotic pouch. Verdict: “Death was the result of misadventure.”

**Oxalic Acid.**—Emma Ridler, aged 43, died on Saturday, April 6, at Stroud, from the effects of oxalic acid, self-administered. Verdict: “Suicide from poisoning.”

**Laudanum.**—Frederick Willett, aged 40, died on Saturday, April 6, in the West Ham Hospital from the effects of laudanum, self-administered.

**Carbolic Acid and Naphtha.**—Barbara Owen, aged 37, died on Monday, April 8, in the Borough Hospital at Bootle from the effects of carbolic acid and naphtha, self-administered. Verdict: “Decesed died from the effects of taking poison, but under what circumstances she took it there was no evidence to show.”

**Carbolic Acid.**—On Saturday, April 6, at Broomhill Station, near Granton, Maschonald, a workman in the Highland Railway employment, went to a cupboard, poured himself out a glass of carbolic acid, and strained it off under the belief, as is conjectured, that it was spirits. Dr. Grant, Granton, was summoned, but the man died within a couple of hours after the fatal draught.

**Oxalic Acid.**—John Speakley, aged 50, died on Friday, April 12, at 73, Shillers Street, Grimsby, from the effects of oxalic acid, self-administered. Verdict: “Suicide whilst in an unsound state of mind.”

**Carbolic Acid.**—William Sydney Moore, aged 70, died on Thursday, April 11, at 179, Wood Street, Kidderminster, from the effects of carbolic acid, self-administered. Verdict: “Suicide in a state of insanity.”

**Carbolic Acid.**—Emily Strange Senior, aged 52, died on Wednesday, April 10, at 98, Lupus Street, Pinkie, from the effects of carbolic acid, self-administered. At the inquest, held on Tuesday, April 16, the coroner commented on the frequency of suicide by carbolic acid, and the fact that, the acid not being scheduled in the Poisons Act, there were no restrictions of any kind upon its sale. Verdict: “Suicide while of unsound mind.”

**Laudanum.**—Thomas Dempster, aged 60, died on Sunday, April 14, in the Royal Infirmary, Glasgow, from the effects of an overdose of laudanum.

**Trade Marks Applied For.**

No. 182,731.—**ANTI-CORROSIVES.**—Tolhurst and Son, 1, Bowling Green Lane, Farrington Road, London, E.C. February 18, 1895. Device and initials of applicants. The essential particular is the combination of devices.

* Compiled from the Trade Marks Journal.
New Remedies.

[The notes given under this heading for the information of dispensers, embody recent suggestions in therapeutics, and cover both new drugs and preparations, and old ones under new aspects.]

NOSOPHEN IN CORYZA AND ECZEMA.—An iodo compound, tetra-iodo-phenol-ptyhalein, obtained by the action of iodine on phenol-ptyhalein, is used in the form of insufflation in acute coryza, chronic rhinitis and as a dusting powder for eczema. It is a yellow, odourless, tasteless powder, insoluble in water, soluble in ether and in chloroform. It contains 60 per cent. of iodine. It behaves as an acid, and combines with bases to form soluble salts. Nosophepine is not toxic, and is said to pass through the body without undergoing decomposition, and therefore without giving rise to excess of iodine in the urine (Semaine Médicale, March 27, 1895).

PARA-CHLORO-PHENOL IN LUPUS.—A paste composed of—

Para-chloro-phenol
Laclolin
Vaselin
Starch

applied to the ulcercations of lupus, previously well washed, causes rapid cicatrization. A 2 per cent. solution of para-chloro-phenol is also one of the best disinfectants for tuberculous sputum (Pharmaceut. Centralhalle, March 21, 1895).

URANIUM ACETATE IN CORYZA.—One drop of a warm solution of 1/4 to 1 per cent. solution of uranium acetate in distilled water, dropped into each nostril and repeated two or three times a day, or a snuff consisting of 1 part of the salt with 100 parts of coffee in impalpable powder is employed with success in cases of acute coryza (S. Stein, Pharm. Centralhalle, March 21, 1895).

AMMONIUM SUCINATE AS A UTERINE ANTISPASMODIC.—Dr. Remy finds succinate of ammonium of great value in cases of labour prolonged by the spasmmodic contraction of the uterus. He exhibits it in the form of a solution of 1 gramme of the salt in 140 grammes of water, the dose of this being a tablespoonful every quarter of an hour until the spasm subsides. It is serviceable both at the first and second stages of labour (Semaine Médicale).

QUINOLINE RHODANATE, A NEW ANTI SEPTIC.—Induced to experiment with sulpho-cyanhydride (ro- danhydride) acid, from the presence of that body in the saliva, which has itself certain antiseptic properties, Dr. Edinger has combined this acid with quinoline, producing pyridin-methyl-rhodanate. Solutions of this body, according to the author, have very energetic bacterioidal properties, the specific microbes of cholera and diptheria speedily succumbing to its influence. The solution is neither odorous nor caustic. A one per cent. solution has also been employed as an injection in gonorrhoea (Semaine Médicale).

VESICAL IRITABILITY.—Dr. Schun states that when vesical irritation arises from an excess of phosphates in the urine, the following mixture alleviates the frequent desire to micturate—

Benzoic acid.................. 8 grammes
Borax.................. 7½ "
Water.................. 225 "

(Le Scalepel).

CAFFEINE IN ASTHMA AND DISEASES OF THE RESPIRATORY ORGANS.—In spasmodic asthma or any morbid condition of the bronchial tubes, even in chronic bronchitis and emphysema, caffeine exercises a beneficial effect, more markedly so in the case of asthma. The citrate of caffeine is administered, either in solution or enclosed in a cachet, doses of 5 grains, being taken by an adult every four hours until the spasm is relieved, after which the remedy may be given at longer intervals to avert any tendency to relapse. In cases of attacks occurring regularly in the early morning, a dose of 5 to 10 grains at bedtime often suffices to avert or modify the paroxysm, and another dose on waking gives permanent relief (Dr. Markham Skerrett, Practitioner, April, 1895).

TEREPI HYDRATE AS AN EXPECTORANT.—Can be given either in perls or in a pill containing terepine hydrate, 3 grains, massed with sugar and gum acacia, or else in a mixture of terepine hydrate, 1 drachm, glycerin sufficient to dissolve, syrup of tolo to 2 ounces. One teaspoonful every three hours (Practitioner, April, 1895).

CHLORINE IN TYPHOID.—Dr. Wilcox states that chlorine can be taken in sufficient quantity to be antiseptic in cases of typhoid, without producing injurious effects. It stimulates respiration and the heart's action, and increases the flow of saliva and bile. By its action on the kidneys it assists in the more rapid elimination of the toxins. The writer uses doses of 1 to 4 drachms of chlorine water every two to four hours (New York Med. Record, February 9, 1895).

Obituary.

Notice has been received of the death of the following:

On April 8, James T. Clarke, Pharmaceutical Chemist, Manchester. (Aged 45.)

On April 12, Dr. Thurstan Forshaw, Smalley, Derbyshire. (Aged 55.) Dr. Forshaw was a pupil of his brother, Mr. T. G. Forshaw, M.P.S., of Bradford, whilst that gentleman was dispenser to the North Staffordshire Infirmary, and subsequently commenced business as chemist and druggist at Bolton. In 1884 Dr. Forshaw attended the course of lectures at the Coombe Lying-In Hospital, Dublin, and graduated L.M. His business as an accoucheur became very extensive, and ultimately he proceeded to study at the Sheffield School of Medicine, and qualified as a medical practitioner, L.R.C.P. Edin. and L.S.A., 1871.

On April 12, F. J. Jackson, Chemist and Druggist, Bawtry. (Aged 70.)

New Books and New Editions.

[Publishers are invited to forward full particulars of new publications, including price.]

MITTEILUNGEN, BOTANISCHEN, AUS DEN TROPFEN. 7 Hft. Brüehische Pilzbienen. Von A. Möller. 11 marks. (Fischer, Jena.)

DISEASES OF THE HEART AND ARTERIES. By J. H. Clarke, M.D. (Gould and Son, London.)

WATERS AND WOODLAND BLOOMS. By E. Step. (F. Warne and Co., London.)
Notes and Queries.

[The Editor will be glad to receive for publication notes of practical interest to pharmacists, and will also endeavour to furnish suitable replies to any queries that may be sent by readers.]

DIPHTHERIA ANTITOXIN.

[835.] The diphtheria antitoxin prepared by Behring and Roux is the most potent, and is obtained by long-continued injection of horses with large doses of pure toxin from diphtheria cultures. Klein, however, has been able to obtain blood serum possessing a powerful immobilising action in respect to otherwise fatal doses of living diphtheria bacilli by injecting horses repeatedly with large doses of living bacilli of increasing virulence.

PRODUCTS OF DIGESTION.

[836.] There are, apparently, two kinds of peptone—hemipeptone, which is split up by the pancreatic juices into leucine, tyrosine, etc., and anti-peptone, which is not altered. Peptone is now precipitated by ammonium sulphate or nitro acid, like the albumoses, which are classified as proto-, hetero-, and deuterio-albumose, according to their reactions and solubilities. Albumin probably consists of hemi- and anti-albumin. On hydration, the former is first split into hemi- and anti-albumose, whilst anti-albumin yields hetero-albumose and acid albumin. Deuterio-albumose is next formed, and finally converted into hemi- and anti-peptone.

FLAVOURING SYRUPS.

[837.] The following recipes for syrup to flavour aerated water are taken from the Era Formulary (Haynes and Co., Detroit, Mich., U.S.A.)—Chocolate Syrup.—Melt with good quality, 2 lb.; granulated sugar, 23 lb.; water, 6 plate; extract of vanilla, 4 oz. Break chocolate into pieces and boil with water until free from lumps, stirring constantly; add sugar and dissolve, then strain through fine sieve; finally, add more water if too thick, or sugar if not sweet enough, and flavour with the vanilla extract when cold. Coffee Syrup.—Make with fresh water, 3 quarts, over night, then steam for two hours and strain. After standing for about two hours, pour off clear liquid through muslin strainer, and make up to 1 gallon with water. Finally, dissolve granulated sugar, 9 lb. Orange Syrup.—Cream and milk, 1 pint each; sugar, 1 lb. Dissolve. Milk Punch Syrup.—Simple syrup, 1 pint; brandy, 8 oz.; Jamaica rum, 8 oz.; cream syrup, 1 pint. See also article on page 915.

FERRO-PRUSIAN PAPER.

[838.] On ordinary ferro-prussiate paper—sensitised by treating paper possessing a smooth surface with a freshly prepared mixture of solutions of iron ammonio-citrate (5 oz. in 1 pint) and potassium ferrocyanide (5 oz. in 1 pint)—the prints show white lines on a blue ground. It is said that blue lines on a white ground may be obtained by sensitising with a fresh mixture of solutions of iron ammonio-citrate (1/4 oz. to 4 oz. water), ferro chloride (1 oz. to 2 oz. water), and gum acacia (2 oz. to 15 oz. water). After a shorter exposure than usual, develop by immersing in a saturated solution of potassium ferricyanide, then in distilled water, next in hydrochloric acid (1 in 12), and finally wash well with water.

TOOTHCACHE WAX.

[839.] The Druggist Circular gives the following formula for 1 lb. preparation—Hare’s paraffin, 1 dr.; Burgundy pitch, 13/4 oz.; molasses, 21/4 oz.; spermaceti, 21/4 oz.; beeswax, 2 oz.; salol, 1 oz.; camphor, 1 oz.; and oil of cloves, 21/4 oz.; of which mix together, heat to 200° F. Melt the first two ingredients together, add the others when nearly cold, and make the mass into pills or small cones.

Trade Correspondence.

THE FIXATION OF PROPRIETARY MEDICINE PRICES.

Sir,—Will you please to let us have the opportunity to contribute a little to the discussion going on in the Press, on the line taken by Mr. Chapman, I have devoted a considerable amount of attention to the subject, and on the whole I must beg to differ from him and Mr. Allen as to the general desirability of anti-competitive schemes. In fact, five years ago a number of friends and I canvassed four or five hundred chemists in business in town and country to ascertain the prevailing view of the trade on the matter. The inquiry was in every respect conducted by The Pharmaceutical Journal at the time, so it will suffice now to remind your readers that the great majority were in favour of restriction. Over eighty per cent. of those asked were willing to sign undertakings not to sell below a stated rate. The prevailing feeling seemed to be that the profit guaranteed should not be too much, because the transaction is a purely trade one (save where there is poison in the article) and it must be in accord with les de mécie principles; also because any extensive attempt to "ride the high horse" would provoke resentment and retaliation on the part of the public. Instead of joining with your correspondents in coldly-drenching the latest converts to phar-maceutic fair-trade, I desire to compliment Messrs. Allen and Hamburys on their pluck and public spirit. It is to be hoped they will be firm and impartial in enforcing their new trade conditions, and also that we in the Pharmaceutical Journal in gratitude to them for their trouble. Now that a great historic house has joined the "Progressives" is it too much to expect that others of the large firms will do likewise? It is worth their while to think it over just now, when "fair" and "anti-sweating" are being so freely discussed everywhere. At the time referred to I wrote to a hundred of the best known makers of proprietary medicines, requesting to be informed if they were favourable to the idea of protecting prices. Most of them were at that time averse to it—perhaps, perhaps, because the idea was very new, and partly because of their dislike to trouble and re-arrangement. A few were strongly inclined to try one or other of the several schemes recommended, only they felt too timid to launch out alone. It may be that the good example now set them by a house so eminent, added to the other good examples that have come from their imitation during the last few years (Elliman, Burroughs, Bloddean, etc.), will stimulate them to action. I think they will find the bulk of the trade ready for an "alliance," "compromise," "burying of the hatchet"—call it what you like. Speaking personally, Ellimans is a plan of campaign designed to alleviate and disintegrate, and trebled sales by chemists.

As regards the rate of profit that should be assured, 3d. in the shilling was suggested in my scheme, but I now think that a little too high. For several reasons 1½d. or 2d. is enough—for coal. The subject is tempting to pursue, only "1½d. in the shilling" does not warrant any greater expenditure of time this week.

Briston, B.W.

WILLIAM JOHNSTON.

Notices to Correspondents.

** Communications should reach the Editorial Department, 17, Bloomsbury Square, W.C., not later than the first post on Wednesday, in order to be despatched in the next issue of the Journal; though prompt publication cannot always be guaranteed.

** Matter intended for publication must be written in ink, on one side of the paper only, and be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.

** Notice can be taken of anonymous communications, and contributors are requested, as far as possible, to append their proper signatures rather than pseudonyms, a greater value being thus given to any opinions expressed.
THE EARLY HISTORY OF PHOSPHORUS.

The term phosphorus was formerly applied to any substance which was luminous, either after exposure to light or after the application of heat, and the "phosphor" which received so large a share of attention, had no connection with the substance now known as phosphorus, and should rather be regarded as the ancestor of the luminous points of to-day.

The peculiar, light-emitting property of the phosphor, however, secured to them so great a popularity among the dilettanti, that when the element was isolated, it was sold at a fabulous price, and was regarded by many as an important step towards the discovery of the divine arcana by which base metals could be transmuted into gold. The value possessed by the so-called phosphorus (a sulphide of borium) of Balduin in the seventeenth century, is well shown in a letter from Christianus Adolphus Fleminus to Mr. Oldenburg, sent with a sample of "phosphoric" in a small girl's box for "His Majesty the Founder of the Royal Society" (Phil. Trans. 1676-7, vol. xi., No. 131, p. 788).

Although, with an unusual extension of the novelist's licence, Charles Reade makes one of the characters in the 'Cloister and the Hearth' use phosphorus in the fifteenth century, it was not until the year 1667, according to some authorities, or 1659, according to others, that it was actually isolated.

The discovery has been variously attributed to Brandt, Kuntz, Kunkel, and Boyle. It would appear that either Brandt or Kuntz was the original discoverer, but there is little doubt that Robert Boyle discovered it independently, for Kunkel himself stated that such was the case (see Kunkel's 'Laboratorium Chymicum,' p. 660, and Weigle's 'Geschicht der Wachsthums und der Erfindungen in der Chemie,' v. i., p. 41).

A paper deposited by Boyle with the secretaries of the Royal Society on October 10, 1669, and opened after his death, shows that he really obtained phosphorus from urine while the German process was still a secret (Phil. Trans., 1660, p. 17, No. 196, p. 520).

Godfrey Hanckewitz, Boyle's assistant, appears to have been most expert in the manufacture, and is said by Thomson ('System of Chemistry,' 1817, v. i., p. 253) to have supplied all Europe for many years. According to Thomson, this phosphorus was known as "English phosphorus," but Heliot, who published the first complete description of the preparation, says that phosphorus was known throughout Germany as "Kunkel's phosphorus" (see 'Memoires de l'Academie Royale des Sciences,' 1737, pp. 369 to 378).

Hanckewitz gives a somewhat different version of the discovery of phosphorus, which will be found in the later portion of this article.

Probably the most reliable account of the discovery is that of Godfrey de Leibnitz in the 'Miscellanea Berolinensia' (1710, v. i., p. 91 to 98). According to this account "Brandt had fallen on a chemical process extant in a printed book, which taught how to prepare from urine a liquor fit to ripen a particle of silver into gold; and in labouring on this he found out his phosphorus. He had some acquaintance with Daniel Kraft of the Council of Commerce to the Elector of Saxony; and by his means, with Kunkel, one of the said prince's bed chamber; but who, under that character, performed chemical processes. On persuading Brandt that this arcana might be sold to the great at a high price, and offering him their assistance, they obtained the composition from him. And upon going from Dresden to Hamburgh they both saw and learned from him the process of the phosphorus. But Kunkel upon his return home had committed some mistake in the process, and for a long time could not hit upon the phosphorus, and he sent a letter to Brandt, complaining that the secret had not been sinned upon to him. But Brandt told him that he was in error in inverting the secret, delayed to satisfy him. Kunkel in the meantime, after various trials corrected the error himself, whence he pretended to be the inventor, and of this Brandt bitterly complained.

"Kraft, who was a man of good address, undertook to vend the discovery among the great; and, in his way to England he made a visit at Hanover, and ingenuously mentioned to me both the master of the process and its author, Brandt; and he likewise showed the experiment of the phosphorus to the great surprise of Duke John Frederic, and afterwards in England to King Charles II., Prince Rupert, the illustrious Mr. Boyle, and others, of which there is an account by Dr. Hooke. But he never, so far as I know, mentioned himself as the inventor. The phosphorus was first sent into France by me to Huygens, and at length the composition itself was by the illustrious Tschirnhausen, upon his return from Germany into France, communicated to me to the Royal Academy, to whom Huygens had already shown the same; and it has since been put by an imperfect description of it appears from his dissertation on phosphorus; for his phosphorus differs from Brandt's only in this, that it is more imperfect.

"But Duke John Frederic, as he was a magnificent and generous prince, ordered that I should send for the inventor. Brandt, therefore, came to Hanover and faithfully communicated to us the process, for whatever he did I imitated in another laboratory. Upon collecting a large quantity of urine, Brandt came to us, and we went through the process. Upon Brandt's return to Hamburgh, the duke settled an annual pension upon him, which was punctually paid him till the duke's death; and this probably was the only considerable encouragement which he reaped from his phosphorus."

Dr. Kunkel's phosphorus or "noctiluca" was also described in the 'Philo"enical Collections of Mr. Robert Hooke' (1651, No. 2, p. 8) by Dr. Sturm, who stated that Kunkel could extract phosphorus "out of any kind of terrestrial body whatever, as if it were there naturally placed."

Regarding to the singular properties possessed by phosphorus, it occupied the attention of all the principal chemists whose writings are extant in the scientific literature of the period. Among these may be mentioned Tschirnhausen ('Ainie Memoires de l'Academie Royale de Paris,' 1682, vol. i., p. 342), Homberg (loc. cit., 1692, vol. ii., p. 135), Hofmann ('In Observationibus,' Hall's edition, 1722, p. 336), Theichmeier ('Elementa Philosophiae Naturalis et Experimentalis,' 1724, p. 43), Nieuwentvort ('Existence de Dieu Démontrée par le Phosphore,' p. 524), who obtained phosphorus from "old urines," which he collected from a hospital; Margraf, who gave in the 'Miscellanea Berolinensia' (1743,
v. vii., pp. 334 to 344) a plate of figures showing the furnaces which he employed, and others whose work is referred to later.

According to Chambers' "Encyclopedia" (1733), a Mr. Elzeiht published in 1765 a special treatise dealing with phosphorus, and the "Aérial Noctilucas" of Boyle (1680), bearing on the subject, is well known.

The process employed by all the earlier investigators consisted in evaporating urine (which contains about 0.032 per cent. of phosphorus) to dryness and distilling the residue until the phosphorus passed over, and considering that the chemists of the period adopted the process of destructive distillation as the best means of ascertaining the composition of nearly all organic bodies, it is remarkable that the discovery was not sooner made. The most successful workers appear to have been those who were most experienced in the use of furnaces, but some of them laid great stress upon the source of the urine, and that of beer-drinkers appears to have been in especial favour. Boerhaave ('A New Method of Chemistry,' Translated by Shaw and Chambers, 1727, p. 196), however, says that the best is that from persons not much accustomed to drink wine.

Homberg mixed the dried urine with red bale, Boyle employed white sand, and Boerhaave powdered charcoal, but a very considerable improvement was introduced by Marggraf, who added lead chloride to the dried urine, and by Gichter, who first precipitated the phosphoric acid with lead nitrate and distilled the lead phosphate so obtained, with charcoal ('Annales de Chimie,' v. 12, p. 10).

The ignorance which prevailed among chemists as to the true nature of phosphorus is well shown in the following account from James' 'Medical Dictionary' of 1746:

"Dr. Wall informs us that Mr. Boyle, being concerned to find how small a proportion of phosphorus was afforded by urine, desired him to look out for another subject that might afford it in greater plenty. The doctor afterwards causing a piece of dry matter to be dug up in the fields where night-men emptied their casks, he observed a great number of small particles of phosphorus therein. This matter the doctor immediately carried to Mr. Boyle, who set Bilgar, the chemist, to work upon it. But he could obtain very little phosphorus from it till another material was added to it in distillation, and then he procured phosphorus in such plenty that, selling large quantities at six guineas the ounce, he soon became rich, and left England." It should be mentioned that Bilgar was assistant to Boyle before Hanckewitz.

It is probable that, by the end of the seventeenth century, no substance had been so fully and accurately experimented upon, although the explanations of its action and the anticipations of its value were often expressed in almost ludicrous terms. Dr. Frederick Slaar (Hooker's 'Philosophical Collections,' 1681, No. 3, p. 48, and No. 4, p. 84) says that it was then obtained as transparent as any resin and melted like wax in warm water. His remarks show that it was even then obtained in a state of great purity, and he finishes his paper by saying "what medical use may be made of this noble concrete time may discover," adding the hope that it may explain "certain phenomena of Nature, including the observation of the learned Dr. Croone, who, on rubbing his body with a fresh and well-warmed shift, made both to shine."

An amusing example of the almost religious ceremony with which phosphorus was treated is found in the Philosophical Transactions (1733, vol. 38, No. 428, p. 55), where a description and an elaborate drawing of an apparatus employed for burning phosphorus is described by Dr. Frobenius, the companion of Hanckewitz. The phosphorus was ignited in a golden bowl, contained in another golden bowl on a tripod of the same metal, a glass bell-jar being suspended above to receive the "snow" which the combustion produced. The apparatus was described as the "Machina Frobeniana," and each operation was compared with one of the phenomena of Nature, the phosphoric anhydride to snow, and its deliquescence to the melting of snow. In this and similar experiments the learned doctor in the hall of the house, igniting the phosphorus with the heated tip of his sword.

Almost immediately afterwards, Hanckewitz (loc. cit. p. 58) showed that the Machina Frobeniana was unnecessarily elaborate, and repeated the experiment in a "warmed china cup." He mentioned the production of amorphous phosphorus as a "red caput mortuum" and gave a very complete description of his experiments, observing that "this phosphorus is a subject which occupies much the thoughts and fancies of some alchemists who work on micromolecular substances, and out of it they promise themselves golden mountains." According to him, Kunkel, Kraft, and Brand were only able to obtain a little "unctuous opaque phosphorus," and not the true hard "glacial" phosphorus. He considered that Kunkel either spoke too much at large or designed to impose upon the world, and stated that at the time of speaking, he was the only man capable of making real phosphorus. Hanckewitz was undoubtedly the principal maker of phosphorus in his time and it is interesting to note that he was the founder of the firm of Hanckewitz, who still manufacture a good many of the chemicals. A paper of information on the work of Hanckewitz was given in a paper by Mr. Joseph Inos in the Pharmaceutical Journal (1886, pp. 126,157, and 215).

The chemical properties of phosphorus were carefully studied immediately after its isolation, and the discovery that it increased in weight on burning, which is attributed to Marggraf, is said to have been in part responsible for the overthrow of the pilogiston theory, for Lavoisier showed that it increases in weight when burned in oxygen equalled the loss of oxygen in the same weight of phosphorus appears also to have been the first to definitely show that phosphorus was an element, and to point out its wide distribution throughout the vegetable kingdom (see Lavoisier's 'Elements of Chemistry,' Translated by Kerr, 1809, vol. i., p. 323).

Priestley also examined its action on burning in air ('Experiments and Observations on Different Kinds of Air,' 1790, vol. i., p. 170).

The action of phosphorus on metals was experimented upon by Marggraf, and later by Peltier, who found that most metals combined with it when heated. Dr. Peter Shaw (James' 'Medical Dictionary,' 1745, article "Phosphorus") says that the "acid of phosphorus proves a menstruum to perhaps all the metals, but when this acid is driven into the pores of the metal by the action of the flame in burning the phosphorus, it seems pro-
ductive of much greater effects, as is well known to those connected with the sublimer metallurgy."

The production of amorphous phosphorus curing the distillation of phosphorus was early known, but it was not recognized as a form of the element, but as an oxide. Aikin ('Dictionary of Chemistry and Mineralogy,' 1807) described it as "a brown red powder which diffuses itself in water like clay, and consists chiefly of phosphorus so peroxygenated as to be no longer combustible."

The modern method of preparing phosphorus is beyond the province of this article, but it may be mentioned that Gahn, a Swedish chemist, showed in 1789 that phosphorus was contained in bones (see 'Bergmann's Notes,' 1796, p. 203), and that the credit of preparing it from them appears to be due to Scheele. In 1775 he obtained it by treating bone-ash with nitric acid, precipitating the lime from the solution by addition of sulphuric acid, evaporating the solution and distilling the residue with charcoal. Nicolas and Pelletier ('Journal de Physique,' vol. 11 and 28) improved upon the process by dispensing with the use of nitric acid, and Fourcroy and Vauquelin ('Journal de Pharmacie,' v. i., p. 9) determined the proportions most suitable for operations on the large scale. Aikin ('Dict. of Chem. and Min.,' 1807) mentions as a good yield, that Pelletier obtained 60 ounces of phosphorus from 576 ounces of bone-ash.

It was also common at the commencement of the present century to prepare phosphorus by precipitating the phosphoric acid from superphosphate of lime with lead nitrate, and distilling the phosphate of lead thus produced, with charcoal (Rees 'Encyclopedia,' 1819).

THE SOLUBILITY OF QUININE IN ALKALIES.*
BY PROFESSOR E. DOUMER AND M. DERAUX.
(Continued from page 918.)

EFFECT OF THE ALKALINE CARBONATES.—The exceptional behaviour of potash and soda, in relation to the solubility of quinine, has led us to think that the carbonates which accompany these alkalies must be the cause of it, and to make the following experiments:

I. Effect of Sodium Carbonate.—In order to study the effect of carbonate of soda on the solubility of quinine in alkaline solutions, we have adopted a method similar in all respects to the preceding one, that is to say, we have determined the solubility of quinine by means of solutions, all of which contained the same weight of soda or ammonia and variable weights of carbonate of soda.

Table IV.—Soda and Sodium Carbonate.

* From the Journal de Pharmacie et de Chimie.

It is clear, judging from the figures contained in the preceding table, that the solubility of quinine in solutions of caustic soda diminishes in proportion as the solution becomes more carbonated.

It is therefore possible, from these first results, that the way in which commercial soda affects the solubility of quinine depends on the fact that this alkali is generally carbonated, we see, therefore, that if we work with a very dilute solution of soda, the amount of carbonate present in the soda being very small, the effect upon the solubility is very nearly nil; on the contrary, if we work with a very concentrated solution, the amount of carbonate is naturally greater, and consequently its influence in the solubility more marked. Whatever the value of this attempt at explanation may be, we can draw a practical conclusion of the highest importance from the preceding results; it is, that in order to obtain a most perfect precipitation of quinine by soda, it is best to use an alkaline liquid very much carbonated.

We also see, as a consequence of the foregoing, that when we wash the precipitate with distilled water, after having precipitated the quinine with solution of caustic soda, the first washings constitute a diluted solution of soda, and will re-dissolve a portion of the precipitate; we have there a source of error, as to the extent of which we can hardly be decided.

Table V.—Ammonia and Carbonate of Soda.

This table is exactly comparable to Table IV., and the same remarks are exactly applicable to it.

II. Influence of carbonate of ammonia.—Carbonate of ammonia gives results entirely different to those obtained with carbonate of soda, as the two following tables show:

</table>

In fact, we see from Table VI. that the solubility is greater in the solution of soda to which carbonate of ammonia has been added than in solution of soda alone. This fact was easy to foresee from another reason, because the soda displaces the ammonia, and thus gives rise to a weak solution of ammonia whose solvent power is greater than that of the solutions of soda used.

It differs with solutions of ammonia and carbonate of ammonia, because the solubility of quininised is proportion as the amount of carbonate of ammonia increases; but it will be noticed that this diminution is not nearly as great as when, other things being equal, we substitute carbonate of soda for carbonate of ammonia. The use of carbonate of ammonia to facilitate the precipitation of quinine is therefore to be rejected, and it is best, for this purpose, to give preference to carbonate of soda. We give an example which will illustrate the effect of carbonate of soda on the precipitation of quinine by the alkalis. Let us take for instance the precipitation of 1 gramme of quinine as sulphate dissolved in 100 C.c. water. If we perform the precipitation with 100 C.c. of pure ammoniacal solution of 4 or 5 per cent. strength we shall only precipitate 1 Gm. less 0.09 Gm. = 0.91 Gm.

If, on the other hand, we precipitate with 100 C.c. solution containing the same quantity of ammonia, and, in addition, 13 or 14 grammes of carbonate of soda, we shall precipitate 1 gramme less 0.01 gramme = 0.99 gramme quinine, that is to say, nearly the theoretical quantity. If we precipitate with soda we shall get quite analogous results, that is to say, we shall recover more quinine if precipitated by means of a mixture of soda and carbonate of soda than by the use of pure soda. In order, therefore, to obtain a more complete precipitation of quinine by alkalis, it is necessary to make an addition of sodium carbonate.

Notes on Recent Scientific Investigation.

A New Class of Organic Sulphur Compounds.—When sulphur monochloride, S₂Cl₂, reacts with piperidine, C₅H₇N, a compound is obtained which may be regarded as a disulphide of the base, and has the formula (C₅H₇N)₂S₂. Michell and Luxembourg (Ber., 28, p. 165), have shown that a similar reaction occurs with the secondary aliphatic amines. By acting upon dimethyamine with sulphur monochloride in ethereal solution, the dithiodimine and dimethylamine hydrochloride are produced—

\[4\text{(CH₃)}₂\text{NH} + \text{S}_₂\text{Cl}_₂ = 2\text{(CH₃)}₂\text{NCl} + \text{S}_₂\text{HCl}\]

The corresponding ethyl compound was also prepared they are both liquids, distilling undecomposed under reduced pressure, but decomposing when boiled at the ordinary atmospheric pressure. Acids decompose the compounds, yielding the salt of the secondary aliphatic amine, sulphur, and sulphurous acid.

The dithiodipiperidine is a substance crystallising in white plates from alcohol, and is more stable than the methyl and ethyl compounds, since it can be boiled with water without decomposition. Acids, however, effect the same change as with the above-mentioned substances. It is probable that all the secondary amines yield similar compounds.

New Compounds of Phosphorus, Nitrogen, and Chlorine.—H. N. Stokes describes in his American Chemical Journal a series of new compounds of phosphorus, nitrogen, and chlorine, and a series of acids derived from them. He finds that the chloro-phosphur of nitrogen, P₃N₄Cl₁₀, discovered by Liebig in 1832, is a member of a homologous series the general formula of which is (PNC₁₄)ₙ, and that the metaphosphinic acids of which they are the chlorides have the general formula (PNO₄Hₙ)n. The compound (PNC₁₄)ₙ is almost as stable as (PNC₁₄)₁, and yields an equally stable acid (PNO₄H₂)n on saponification. A higher chloride (PNC₁₄)ₙ possesses an oily character. Very large crystals of the triple compound, the corresponding acid of which has also been isolated, were deposited from benzene. They melt at 114°, while those of (PNC₁₄)₁ melts at 123°-5 and boils at 253°-5. The acid produced on decomposition of the quadruple compound, by dissolving in ether and agitating with water, forms crystals of the composition (PNO₄H₂)ₙ + 2 Aq. Soluble chlorides, nitrates, and sulphates are decomposed by this acid to form three series of salts.

Carbon Monosulphide.—This compound has been obtained by Dr. Deninger, of the Dresden Laboratory, by heating to 180° anhydrous sodium sulphide with excess of chloroform, in sealed tubes, thus:

\[3\text{Na}_₂ \text{S} + 2\text{CHCl}_₃ \rightarrow \text{H}_₂ \text{S} + 6\text{NaCl} + 2\text{CS}_₂\]

The new sulphide, which passes through caustic soda solution practically unaltered, is also evolved on heating a mixture of silver sulphide and iodine thus:

\[3\text{Ag}_₂ \text{S} + 2\text{CHCl}_₃ \rightarrow \text{H}_₂ \text{S} + 6\text{AgCl} + 2\text{CS}_₂\]

It is gaseous at ordinary temperatures, combustible, and rapidly absorbed by aniline, or alcohol. Ordinary freezing mixtures readily condense it to a clear, colourless liquid.

FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, APRIL 27, 1895.

Editorial Department.

Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

Advertisement Department.

Advertisements and remittances must be sent to "Street Brothers," 5, Serle Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased, and to whom Cheques and money orders should be made payable.

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary — Mr. Richard Brenbridge, 17, Bloomsbury Square, London, W.C.

APPRENTICESHIP IN PHARMACY.

At the present day there is a very marked tendency in the United States of America to belittle the importance of "the education of the shop" in pharmacy, and a few irresponsible and ill-informed individuals in this country have adopted a similar tone. To those, therefore, who are capable of appreciating the advantages of the older system and consider it, when properly supplemented, capable of affording better results than can be obtained by any system of mere college training, however elaborate, the opinions expressed by Professor Remington in the American Journal of Pharmacy for April possess a special interest. They are of the greater value, too, in that he prefaces them by asserting that there are yet thousands of conscientious pharmacists who do not consider those in their service as mere money-getting machines, but view them as the pharmacists of the future, with like responsibilities to themselves. He considers it as unfortunate, therefore, that attempts should be made to ignore the value of shop experience. The system proposed as a substitute, by which students may gain a diploma without being required to show proof of such experience, is stated to be an illogical and unwise one, for it is impossible for anyone to be fitted to fulfill the duties of a practical pharmacist without having had some experience in a pharmacy.

It is unreasonable to suppose that a pupil can serve four years in a shop and learn absolutely nothing. More or less unconsciously he is bound to acquire a mass of practical information which cannot be gained in any other way, and would be difficult to pick up after graduation. This is an inevitable result of apprenticeship, whether or not employers set to work to train their pupils systematically for their future career. "And is it possible," asks Professor Remington, "for one who has never served a day behind the counter, and yet passed a successful examination, to be expected to equal in efficiency one who has served four years and, in addition, had his college education and passed his examination besides?" Certainly not! most if not all practical pharmacists will reply to this, as well as to the further question whether it is advisable for colleges of pharmacy to throw away this immense advantage which the pharmaceutical student possesses over all other professional students, of actually practicing pharmacy, either before he comes to college or after he has entered it?" The diploma of a qualifying body must be more valuable if practical experience be required before graduation. Whatever self-classed educational reformers may urge to the contrary, pharmacists should maintain the only truly logical position and affirm that college work should supplement, not supplant, shop training. To ignore the value of the latter is to throw away an advantage of the first importance, and, as Professor Remington prophetically remarks, when the pharmacist's work in the training of pupils is counted as nothing or worse than useless, then may we look for the decadence of pharmacy.

The same question has quite recently been dealt with from the medical point of view by Dr. J. G. Glover, in his presidential address to the North London Medical and Chirurgical Society. The old-fashioned system of apprenticeship in medicine has fallen into almost total disuse, but Dr. Glover considers that a certain amount of pupilage in general practice is of great importance in the curriculum of medical education. He and other leading medical practitioners have endeavoured, and with partial success, to get this truth recognised by the General Medical Council. "Just as men need to have lessons in hospital practice," he contends, "so they need lessons in general practice. The practice is quite different. The very cases are different, and their management and even treatment are different. But especially the cases are different. The great bulk of the cases that constitute general practice are conspicuous by their absence in the wards of a hospital, and would be considered uninteresting, so that it is possible for a distinguished student, and even one who may have been a resident physician and surgeon, on commencing general practice, to find himself in considerable difficulties alike of diagnosis and of treatment." In this education of the medical student in common diseases, that would result if pupilage in general practice were more common, Dr. Glover believes is to be found one of the best ways of meeting the unfair competition of "that arch-generalist, the prescribing chemist." Similarly, it may reasonably be maintained that by maintaining apprenticeship in pharmacy, and perhaps in that way only, pharmacists may expect
to hold their own against other traders. For, as regards the trade aspect of pharmacy, the chief factor of success is undoubtedly the possession of a sound business capacity, which should be acquired early rather than late in life, and cannot possibly be obtained by the longest conceivable course of college training, but must be gradually developed in the shop.

**PHARMACY IN DENMARK.**

In an article in the *Journal de Pharmacie et Chimie*, by A. Wunsch, a Danish pharmacist, it is stated that there are 169 pharmacists in Denmark, Iceland, and the adjacent islands, i.e., about 1 per 13,577 of the population. Copenhagen, the capital, with a population of 312,859, has but 21 pharmacies, or 1 per 14,986 individuals. The licences to carry on business are either "real" or "personal." The former, none of which have been granted since 1842, number 89, and are identified with certain pharmacies which may be sold and bought with the licences attached. The purchaser must in any case be 25 years old, and possess a satisfactory diploma. Pharmacists in Copenhagen must have their diplomas endorsed "very good," whilst those who simply have the mark "good" may practise pharmacy anywhere else throughout the country, and those whose diplomas are marked "medium" only must be examined anew before they can practise.

The course of study in sisted upon extends over six years, three years as pupil in a pharmacy, one as assistant, and eighteen months at the school of pharmacy. According to the most recent legislation, all licences granted in future will be personal only, expiring with the death of the holder. The widows of deceased pharmacists are allowed, however, to carry on business provisionally, though for a long period, if a properly qualified pharmacist is in charge, and 18 out of the 81 businesses with personal licences now belong to widows. Both pharmaceutical and medical affairs are administered by a Sanitary Commission, under the direction of the Minister of Justice. The Commission is composed of nine doctors and two pharmacists. It regulates the official tariff for medicaments, decides what new pharmacies shall be opened, selects a list of three applicants for each vacancy, etc., etc.

There are said to be 1006 qualified pharmacists who have not yet been successful in obtaining the necessary licence, and more than half of them are therefore engaged abroad or occupy themselves with other occupations. Some 300 gain living as assistants at a salary of 140 to 200 francs per month, and the average age at which they may expect to receive personal licences is 45 to 50. It is clearly advantageous, therefore, to be in a position to purchase one of the pharmacies with "real" licences attached, though it is usually necessary to pay for such a sum equivalent to seven times the annual takings. As illustrating how the cost increases in course of time, it is stated that the Lion pharmacy in Copenhagen, which sold for 224,000 francs in 1835, realised 574,000 in 1889, whilst the price of a Jutland pharmacy advanced from 119,000 francs in 1835, to 714,000, in 1888.

**PHARMACY LAW IN AMERICA.**

According to the *New England Druggist*, Mr. N. H. Martin’s criticisms of American pharmacy have succeeded in drawing marked attention to American weaknesses in pharmacy as a nation, and it is stated that the natural sequence is now beginning to appear in suggestions for a remedy. "State pride and loyalty have prevented such a frank avowal of general weakness as Mr. Martin has proclaimed for us, but it has shown us very clearly that the strength of a profession, like that of individuals or physical objects, is gauged by its weakest part."

The favoured remedy appears to be a national pharmacy law. As is doubtless well known to our readers, the various States of the North American Union have pharmacy laws which are quite independent of each other, and are described as being dominated in most cases almost wholly by the interpretation placed upon them by the individuals who constitute the State Boards of Pharmacy. There is no central authority, like the Pharmaceutical Society in this country, and the variations in the educational requirements, etc., are so great that no State will recognise the certificates of other States.

The publication of a national pharmacopoeia, the organisation of a national association, and the establishment of a national formulary have done much to unite the various sections "in aims and ideals as well as in standards," and it is urged that it now remains for the United States to complete the national recognition of pharmacy by a national pharmacy law which shall govern all sections alike. "This, it is pointed out, "would mean a uniform standard of education, a common poison register, a better control of the liquor question, and a much greater stability in all matters pertaining to the laws."

**DEATH OF AN ANNUITANT.**

We regret to announce the death, on the 16th inst., of George Chetham, aged 82, chemist and druggist, formerly of Hope, near Sheffield. Mr. Chetham was elected an annuitant on the Benevolent Fund in 1892.

**ESSENTIAL OILS.**

The attention of our readers is specially directed to the important communication on essential oils, by Mr. J. C. Umney, part of which we publish this week. An enormous amount of work is represented in the published results, much of which will doubtless prove of considerable value to pharmacists generally.
Transactions of the Pharmaceutical Society of Great Britain.

EXAMINATIONS IN LONDON.

April, 1896.

(Concluded from page 921.)

MINOR EXAMINATION—PASS LIST.

FIRST EXAMINATION.

Certificates by approved examining bodies were received from the under mentioned in lieu of the Society’s Examination:

FIRST EXAMINATION RESULTS.

A meeting of the Board of Examiners for England and Wales was held on Wednesday, 24th instant.

The report of the College of Preceptors on the examination held on April 9 was received.

Three hundred and ninety-four candidates had presented themselves for examination, of whom two hundred and five had failed. The following one hundred and eighty-nine passed, and the Registrar was authorised to place their names upon the Register of Apprentices or Students:

The examinations were held at 13 centres, with a total of 234 candidates.
Pharmaceutical Society.

NORTH BRITISH BRANCH.

MEETING OF THE EXECUTIVE.

A meeting of the Executive of the North British Branch was held in the Society's House, 36, York Place, Edinburgh, on Friday, April 19, at 12 noon, Mr. J. Laidlaw Ewing in the chair.

Apologies for absence were received from Messrs. Hardie and Kinnimont.

The minutes of last meeting were read and approved.

General Purposes Committee.

The report of the General Purposes Committee dealing with details of the opening of the new premises and the evening meetings was read and adopted.

The CHAIRMAN explained that the removal of the examination and evening meeting work to the new premises necessitated some rearrangement of the older part of the Society's premises. He suggested that they should appoint a small committee to look into the matter and prepare a report for consideration by the Council.

Messrs. Ewing, Lunan, and Nesbit were appointed a committee for this purpose.

Annual Report.

The Executive went into committee to consider the annual report of the Council, and, on resuming,

Mr. KERMATH moved that the report be adopted and forwarded to the Council. He said he thought they could congratulate themselves on being able to make a satisfactory report. He was delighted to hear that the plan of appointing teaching examiners had proved so far successful. There could be no doubt a step was desirable, and it was gratifying to find it had resulted as reported.

Mr. FISHER seconded the motion, and it was unanimously agreed to.

Votes of Thanks.

Mr. STORRAR said before leaving the subject of the annual report he thought they should agree to insert in their minutes their thanks and sense of appreciation of the great amount of work that had been done by the Chairman and the Assistant-Secretary in connection with the erection and opening of the new premises. He therefore moved that that should be done.

Mr. KERR, Vice-Chairman, said he had great pleasure in seconding the motion. Being a member of the General Purposes Committee he had an opportunity of seeing really how large an amount of work had to be done.

The motion was cordially agreed to, and the Chairman briefly expressed his thanks.

Election of Executive.

On the motion of Mr. Sutherland, seconded by Mr. Davidson, it was agreed:

"That the next election of Executive take place on Friday, June 21, and that the Chairman and Vice-Chairman be appointed scrutineers of the voting papers, with power to add to their number."

The Metric System.

A letter was read from the Secretary to the Edinburgh Decimal Association, asking the Executive to forward a resolution in favour of the general adoption in this country of the metric system, legalized by the Weights and Measures Act, 1878, to Sir Henry Roscoe, M.P., Chairman of the Select Committee of the House of Commons on Weights and Measures.

It was decided that, in view of the fact that this matter had already been considered by the Council, and that the President had been appointed to appear as a witness before the Parliamentary Committee, no action should be taken.

The Sale of Methylated Spirit.

Mr. SUTHERLAND said he would like to bring before the Executive the subject of the sale of methylated spirit by medical prescription on Sundays. He thought the Inland Revenue should be communicated with so as to have some clear understanding of their position. In his district some chemists had been supplying the spirit in such cases and forwarding the orders to the Revenue authorities, but there was a doubt whether that was the right thing to do. He believed Revenue officers were attempting to get sales of methylated spirit on Sundays by the use of fictitious medical orders to see if chemists were keeping the law.

The CHAIRMAN said a notice was printed in a recent Chemist and Druggist Diary, indicating that in such cases the Inland Revenue authorities would not interfere. He thought they were quite safe with such an arrangement.

Mr. CURRIE said he had heard of such cases as Mr. Sutherland referred to having happened in various parts of Glasgow. He had himself been applied to by a Revenue officer whom he happened to know and whom he, of course, did not supply.

Mr. NERBT said he had been applied to for spirit for a bronchitis kettle frequently. In such cases he got the doctor to mark the purpose for which the spirit was required, and he then supplied it. He did not think chemists would be interfered with in such cases any more than publicans or spirit merchants who supplied liquor by medical prescription on Sundays or at other prohibited hours.

Mr. HENRY said one chemist had supplied the spirit and sent word to the Revenue of what he had done, but no notice was taken.

Mr. STORRAR said this was a matter in regard to which the less that was said the better. There had been no interference and no prosecution.

The subject then dropped.

Examination Business.

Mr. STRACHAN drew attention to the fact that addresses of Major and Minor candidates were not now published in the Journal, and it was remitted to the Scottish members of Council to see if the old method could not be continued.

The meeting then closed.
CHEMISTS' ASSISTANTS' ASSOCIATION.

At the meeting of this Association on April 25, the following paper was communicated:—

**Essential Oils in Their Relation to the British Pharmacopoeia and Trade.**

By John C. Umney.

The title of this paper indicates the scope of the subject which I have chosen to bring before you this evening, and makes it evident that the two objects which have occasioned the choice of it cannot possess any claim to originality. The revision of our national Pharmacopoeia in the near future, combined with the unsatisfactory condition of essential oils as met with in trade, induced me to consider how nearly the requirements of such a work might be made to accord with the physical and chemical characters of the purer commercial products. It would obviously be unjust to compare the British Pharmacopoeia of 1885 with the German Pharmacopoeia of 1890, or the United States Pharmacopoeia (1890), official from January 1, 1894, as in the interval between the respective dates of publication the value of constituents of essential oils made in the study of the constitution of essential oils. It is not, on the other hand, contended that the British Pharmacopoeia of 1885 contained all the characters and tests for these bodies available at the time of its issue, but an endeavour was made to secure uniformity by the insertion of the words "distilled in Britain" as a requirement in the case of the majority of the essential oils. Such restriction is undesirable from every point of view, except in those cases where the climate or soil influence the character of the oil obtained from the plants of the same species, as appears to be the case with lavender and peppermint when cultivated in Britain.

One tread on dangerous ground in discussing the scope of a national pharmacopoeia, and in urging that it should contain not only essential oils that have value in medicine, either directly by their action or as flavouring agents, but also others for which owing to their extensive employment in pharmacy, it is desirable to set up standards of purity. This seems desirable, however, if the British Pharmacopoeia is to be recognised as a legal standard by which the requirements of a "Sale of Drugs Act" may be enforced with something approaching uniformity. It is gratifying to note that in this country, more than that in the editions of the pharmacopoeias of both the United States and Germany include oils of bergamot and rose, whilst the tendency to exclude certain oils, the active ingredient of which is contained in them in common with, but in less proportion than, others that are made official, is rather to be deprecated. If the lead of the Pharmacopoeias under notice in excluding cinnamon oil in favour of cassia oil, presumably in view of its higher average content of cinnamic aldehyde, were followed up in a new B.P., it would lead to the removal of oil and pimento oils in favour of those of caraway and clove, whilst if the value of eucalyptus oils was proved to be due to eucalyptol, cajuput oil, with its larger percentage of that body, might replace it. The Pharmacopoeial description, characters, and tests should embody in every instance: (1) the source of the oil, defining, if possible, the precise species to be used should multiform species be employed; (2) range of specific gravity at 15° C., or at such other temperature as may be convenient in the case of oils solid or partially so at that temperature. In addition to these general requirements it seems desirable to add more extended physical tests where such are capable of indicating purity or otherwise, and in some instances quantitative as well as qualitative chemical tests, where the former may be conveniently employed for ascertaining the proportion of any well-defined body on which the value of the oil is dependent. The following are suggested as more generally applicable:

**Optical Rotation.**—Conveniently expressed for uniformity as a rotation observed at about 15° C. in a tube of 100 Mm. in length.

**Solubility** in alcohol of various strengths or other solvents which indicate distinguishing characteristics.

**Boiling Point.**—As showing range of some approximately constant constituent.

**Chemical Tests (Qualitative).**—Such as absence of acidity (freely indicative of age or oxidation) or reactions showing presence of well-defined chemical bodies (phenols, aldehydes, etc.).

**Chemical Tests (Quantitative).**—Such as the determination of aldehydes, phenols, etc., by processes sufficiently simple to be easily applicable.

The use of the following oils is limited as to suggest their exclusion from a new British Pharmacopoeia:—Chamomile, copaiba, rue, savin, and possibly spearmint, whilst the inclusion of those of bergamot, bitter orange, rose, and possibly synthetic winter-green oil (methyl salicylate) are recommended for reasons which will be more fully considered in the paper. The trade aspect of essential oils cannot be said to be complimentary to British industry, and it may truthfully be urged that in few branches of the manufacturing pharmacist's calling has less progress been made during recent years than in the distillation of essential oils in England. Almost the whole of the scientific research on these complex substances and the chemical nature of their principal constituents has been carried out on the Continent, principally in Germany, and this has tended to increase considerably the import trade of this country in essential oils. It is true, however, that another important factor has contributed even more to this increase, the unfortunate word "price." The employment of essential oils in enormous quantities for perfume, toilet, and other industrial purposes by others than pharmacists, as well as, it may be added, for cheap veterinary medicines, has done much to swell the traffic from the Continent, particularly from France and the Belgian countries; and the enormous imports of spike lavender, juniper wood, rue, savin, and bitter fennel oils consisting to a very large extent of turpentine, are unfortunate instances of such trade. The words "distilled in Britain" it is true have to a very considerable extent kept up the standard of essential oils used for pharmaceutical purposes, as the distillation has been almost confined to a few firms of repute. The time has now come, however, when scientific knowledge must be applied, as well as commercial honesty to such manufacture; and it is for that reason that such tests for excellence, as with purity, are so much advocated. The quality carefully distilled from properly selected material, should be included in a new British Pharmacopoeia.

It seems desirable to record an objection to the trade use of factitious oils, as a type of which may be taken rhodium oil. This oil is no longer distilled from true rhodium wood, and all attempts to obtain the genuine wood for distillation have been unsuccessful. Its use, as well as that of others of the same class, cannot therefore be too strongly condemned, as their composition must of necessity show the greatest variation. In the following summary of the principal essential oils handled by pharmacists, I have endeavoured to place before you the more interesting results obtained from examination of trade samples during the past three years. Where any great discrepancy has appeared to exist between the oils of commerce and those of believed purity I have distilled oils from average material, in order, if possible, to ascertain the
cause of such differences. In presenting the following notes, which must of necessity be very imperfect, owing to the immense field covered, I desire to express my thanks to Dr. W. E. Ellis, A. U. M., as well as two of my firm's analytical assistants, Messrs. Braithwaite and Swinton, who have helped me considerably in the experiments necessary for this paper.

Anise Oil.—The official description of this oil, which recognizes the oils of both anise fruit and star-anise fruit, differs in this respect from that of almost all the pharmacopoeias, the latter being unofficial in the United States and Continental pharmacopoeias. In a paper which I published in the Ph. J. [3], xix., 644, 649, attention was drawn to the fact that almost the whole of the anise oil of British pharmacy was the Chinese star-anise oil, and for this reason the word "ordinary" in the official description, as applied to anise-fruit oil, is misleading and needs amending. Attention was called in the same place to the range of difference between the normal and abnormal coagulating points of the two oils, which is more marked in the case of the star-anise than anise fruit oil, and is affected by the age and oxidation of the oils. The difficulty of fixing on this account a satisfactory coagulating point has caused the adoption in the German Pharmacopoeia of the melting point of the oil after freezing as the most constant factor, which, it is required, should be at 15° C. This has been subsequently commented on favourably by Squire (Ph. J. [3], xxiv., p. 104) and Schimmel in their half-yearly report, October, 1894, who state that the melting point should not be, at any rate, below that figure.

The specific gravity of ten samples of oil of both anise and star-anise examined varied between 0.975 and 0.990 at 15° C., and yielded on fractionation from 80 and 85 per cent. boiling between 225° C. and 235° C., corresponding to nearly that percentage of pure anethol. The optical rotation of the oils examined varies between -1 and 3 at 20° C., being in the opposite direction to that of fennel, which is dextrorotatory to the extent of about +20 in a tube of 100 Mm. Should necessity arise to distinguish chemically between the two oils, and in consequence of the frequent difference in their market value such may be the case, recourse may be had to the colour reaction with a saturated solution of hydrochloric acid gas in absolute alcohol, which affords with anise oil a rich blue, but with star-anise oil a yellowish or brownish colour. (Squire, ibid.)

It is suggested that the official description in the new British Pharmacopoeia should embody the following points:

*Pimpinella anisum.*

*Illicium anisatum.*

Specific Gravity.—0.975 to 0.990 at 15° C.

Melting Point.—After solidifying should not melt below 58° F. (15° C.).

Distinguishing test.—The anise fruit oil affords with sat. solution of hydrochloric gas in absolute alcohol a blue coloration, which is not yielded by star-anise oil.

Bay Oil.—The oil of bay usually met with in commerce consists of a mixture of the heavy and light oils distilled from the leaves of Myrcia (Pimenta) acris. When the oil was first introduced into this country for the purpose of manufacturing bay rum, in consequence of the requirements of the United States Pharmacopoeia of 1880, that it should have a specific gravity of about 1.040, it was customary to find a product consisting principally of the Eugenol-containing fraction, and having a gravity between 1.035 and 1.050 at 15° C.

Latterly, however, the heavy and light fractions mixed in various proportions have been employed, and the requirements of the United States Pharmacopoeia have been modified accordingly, the specific gravity being reduced to from 0.975 to 0.990 at 15° C., and tests added for the absence of clove and pimento oils. The peculiarly pleasant odour of the lighter fractions is thus added to the valuable antiseptic properties of the heavier fractions, which makes the oil one of considerable value.

The samples examined during the past three years show very great variation as regards specific gravity and percentage of eugenol present, several examined fell as low as 0.926, whilst one which contained a considerable quantity of oil of verbenae had a specific gravity of 0.9266 at 15° C.

The finest sample examined had a specific gravity of 0.981, and contained 62.5 per cent. of eugenol when estimated by the process, which will be described under oil of cloves. It formed a clear solution in alcohol of 90 per cent. strength, and showed no indication of oils of pimento or clove oils when treated by the United States Pharmacopoeia test for these oils.

The following table indicates the chief differences between types of the oils rich in eugenol and the lighter oils, all the latter of which, with one exception, are to be distinguished by the only of partially-bulked fractions of the oil obtainable from the leaves:

<table>

The characters and tests of the United States Pharmacopoeia are those, therefore, to which the fine oils respond, and may be adopted as a standard of excellence for this oil.

Bergamot Oil.—The investigations of Schimmel and Co. on the Sicilian and Calabrian essential oils have been most fruitful in stopping the sophistication of these oils, and the method devised by them for the estimation of the odorous constituent of this oil is both accurate and convenient. Linalyl acetate, to which this oil probably owes its aroma in entirety and many others, in part, at any rate, is readily saponified by means of alcoholic potash by boiling for two hours in a water bath with a reflux condenser, and the excess of potash after complete saponification titrated with volumetric sulphuric acid solution. The outline of the method is contained in Schimmel and Co.'s report, October, 1892, p. 38, and details of the process are given in their report, October, 1894, p. 61, together with tables for the ready calculation of sester-content from the saponification figure.

In an examination of a considerable number of bergamot oils, the highest proportion of linalyl acetate I have obtained has been 42.7 per cent., but the percentage in many samples of commercial oil falls to 31 to 32 per cent., four such samples being included in an appended table. Schimmel and Co. state 30 per cent. as a minimum proportion for a genuine pressed bergamot oil, the percentage being but slightly diminished by keeping the oil for a considerable length of time.

* Since the above was written the existence of other phenols than eugenol has been shown, and Schimmel and Co. in their last report (April, 1896) have adopted the process for the estimation of them in this oil, which I have found yield such useful results in the case of the eugenol-containing oils, more especially that of clove. The words "percentage of eugenol" should therefore read "percentage of phenols."
The specific gravity at 15° C. of those oils examined which contained the highest percentage of linalyl acetate varied between 0.883 and 0.885, whilst the poorer oils fall as low as 0.875, which points to admixture with lemon oil.

The behaviour of the oil towards alcohol of 80 per cent., which was a test more generally employed in England before the ester estimation process was devised, is a means of confirming the presence of orange or lemon oils. Pure oil of bergamot, from which the greater part of the stearoptone has been deposited, dissolves in twice its volume of alcohol of this strength without the separation to the bottom of oily drops. In recently pressed oils, however, the separation of the stearoptone makes the result difficult to observe.

The observation of the rotation of the oil is sometimes attended with difficulty, owing to the dark colour of the oil, but by filtration through charcoal, a part of the colour is removed and the process rendered more easy.

The rotation in a column of 100 mm. should not be more than +15 at about 15° C., adulteration with orange oil to the extent of 15 or 20 per cent., raising this figure to +30 or +35; whilst an addition of 10 per cent. of lemon oil raises it to +52, or of 50 per cent., to nearly +26.

The probable condition of purity of the samples is indicated in the table, numbers 1 to 4 inclusive being pure specimens of slightly different quality.

I have not in any case proved the presence of fatty oils, for the detection of which the United States Pharmacopoeia states as a limit that the oil should not leave more than 6 per cent. of residue when evaporated on a water bath, all the samples yielding approximately the same percentage.

Although, therefore, the oil is not actually employed in medicine, it is largely used by pharmacists for other purposes, and doubtless it is on this account alone that it is included in the United States Pharmacopoeia. It might be desirable, therefore, to include the oil in the new B.P., and by that means set up a standard for its purity and excellence, which might be somewhat as under:

Specific gravity at 15° C. — 0.882 to 0.886.
Solubility. — In twice its volume of alcohol of 80 per cent. strength by volume.
Rotation. — Not more than +15 in 100 mm. tube.
Residue. — Not more than 6 per cent. when evaporated on a water bath.
Percentage of linalyl acetate. — Determined by the process recorded above, not less than 38 per cent.

**Cajeput Oil.** — The British Pharmacopoeia describes this oil as the produce of Melaleuca minor, whilst the United States Pharmacopoeia describes it as the product of Melaleuca leucadendron. Other species are also known to yield similar oil, and recently it has been stated that the oil of commerce is distilled exclusively in the comparatively small island of Bouan.

Most of the samples of oil examined during the past three years have varied in specific gravity from 0.922 to 0.927 at 15° C., and have shown by fractionation from 55 to 65 per cent., of cineol (eucalyptol). Two samples recently examined show a much smaller percentage, only 30 and 22 per cent. respectively, and it appears probable that a portion of the cineol has been abstracted for sale as eucalyptol or for increasing the percentage of that body in eucalyptus oils of low eucalyptol value.

The oils show the usual indications of copper by ferrocyanide of potassium, except in the case of re-distilled oils.

Notwithstanding that the oil is employed principally for external purposes, it seems desirable to frame such characters and tests as shall only include a natural oil.

Specific gravity. — 0.922 to 0.927 at 15° C.
Presence of a large proportion of cineol should cause it to become semi-solid on addition of syrupy phosphoric acid, 1:750.

**Caraway Oil.** — In no essential oil, perhaps, do greater differences as regards quality and commercial value exist than in oil of caraway. The three kinds usually met with in trade in this country are:

Light oil of caraway (caraway "chaff" oil so-called)
Oil of caraway from German seed.
Oil of caraway from Dutch seed.

The last named commands about five times the price of the "chaff" oil, and about 10 per cent. more than the oil distilled from German seed.

The requirements of the British Pharmacopoeia that the oil shall "be distilled in Britain" is not in itself sufficient to ensure uniformity as the variety of seed employed yields oil differing in the proportional content of carvol, the principal constituent, the difference in that percentage being greater in oils from German and Dutch seeds than the variation in price already referred to. Doubtless, having in view this divergence in the German Pharmacopoeia, Hl., pure carvol has been made official.

Unfortunately a considerable proportion of the oil used in this country, and imported from Germany, is not employed for pharmaceutical purposes. In the case of oil from chicory seeds, as well as the dill fruit oil, which will be subsequently referred to, they appear to be frequently partially " de-carvo- lised " to meet the Continental demand for pure carvol.

The United States Pharmacopoeia requires the oil to have a specific gravity of 0.910 to 0.920 at 15° C., and the lower limit is certainly one below which the oil should not be allowed to fall.

The estimation of the carvol by means of phenylhydrazine has not been found to yield reliable results, but the fractionation, under precisely similar conditions, shown in the appended table makes clear the differences between types of the usual commercial varieties of oil, comparison being shown with a sample distilled by myself from finest Dutch seeds. It may be noted that the specific gravities and boiling points of the two principal constituents of this oil which have been separated from this oil by repeated fractionation are:

It is suggested, therefore, that the following characters and tests which are those of an oil of good quality be included in a new B.P.:

- Specific gravity not less than -910 at 15° C. Not more than 15 per cent. of the oil should distill below 185° C., and at least 55 per cent. of the oil should distill above 200° C.

Cassia Oil.—The determined stand which has been made by Schimmel and Co. against the adulteration of this oil has done much to check the specification which had reached such alarming proportions. During the past three years I have had the opportunity of examining a large number of samples of this oil; in 1892 hardly any were free from adulteration, it being exceptional for the amount of cinnamon aldehyde to reach 70 per cent.

During the last year, however, out of forty samples analysed only two could be pronounced as undoubtedly adulterated, containing 46 6 and 47 3 per cent. respectively of cinnamon aldehyde, the average amount present in the forty samples being 76 2 per cent. A sample recently examined from a consignment which has been lying at a London Dock warehouse for fifteen years contained 91 per cent., and several samples have been found to contain 80 to 85 per cent. It is not easy to state with accuracy that samples containing from 60 per cent. upwards are adulterated, but it is desirable to fix as high a standard of excellence as possible for this oil, as one can readily distinguish by the strength of odour samples containing 65 and 85 per cent. respectively of cinnamon aldehyde. The aldehyde-content of the oil is estimated by bisulphite of sodium; a most convenient application of which has been devised by Hirschbohn, depending on the solubility in hot water of the compound formed by the aldehyde with the bisulphite, and separation and measurement of the non-aldehyde constituents of the oil.

This oil is official in both the United States and German pharmacopoeias, whilst that of cinnamon (C. ceylanicum) is not recognised. This inclusion is doubtless based on the greater average percentage of cinnamon aldehyde that the former contains as compared with the latter. I am of opinion that such preference is not warranted, as the other bodics present in genuine cinnamon bark oil (some at present undetermined) modify and enhance considerably the value of that oil as a flavouring agent.

It is, therefore, not considered desirable that the lead of the pharmacopoeias already alluded to be followed by the inclusion of this oil in the new British Pharmacopoeia, but the following may be noted as standards of purity and excellence of cassia oil.

Specific gravity according to C.P. 1-050,—1-055.

Cinnamon aldehyde. Should not yield more than 25 per cent. of non-aldehydes when treated with cold sulphide of sodium, equivalent to 75 per cent. of cinnamon aldehyde.

Chamomile Oil.—The oil of Anthus nobilis, "distilled in Britain," is official in the British Pharmacopoeia of 1855 solely for use in the prepara-

Fractionation.

The characters of the pure oil appear to be, therefore:

- Specific gravity.—905 to 912 at 15° C.
- Optical rotation.—+1 to +3.

Cinnamon Oil.—It will be convenient to consider under this heading the oils of both the bark and leaf of Cinnamomum ceylanicum, the former only of which is official, the latter being, however, largely used for soap-perfuming and other commercial purposes. It is unfortunately, moreover, considerably used as an adulterant of the bark oil, and the results recorded below point to a most unsatisfactory condition of most of the bark oil of commerce as imported from Ceylon.
A careful comparison has been made of seven samples of oil, one of which (No. 1) I distilled especially from fine bold cinnamon, whilst Nos. 2 and 4 were distilled by English and German operators respectively.

The specific gravities of these three oils are practically the same, being 1.024, 1.026, and 1.025 at 15°C. respectively, and may be regarded as samples of fine quality, whilst Nos. 5, 6, and 7 imported from Ceylon have a specific gravity of from 1.0379 to 1.0421 at 15°C.

The specific gravities of the cinnamon "leaf" oils examined vary between 1.046 and 1.060, two samples included in a table for comparison with the "bark" oils being 1.054 and 1.055 at 15°C.

The addition therefore, of the leaf oil materially raises the specific gravity, and this character alone in Nos. 5, 6, and 7 points to a considerable admixture of this oil.

This is confirmed by their constitution, for whilst the principal constituent of true "bark" oil is cinnamon aldehyde, that of the "leaf" oil is eugenol. The bark oils having a specific gravity of 1.024 to 1.026, compared from 80 to 70 per cent. of cinnamon aldehyde when estimated by Hirschheim's method for the estimation of that body in cassia oil (which has already been referred to), whilst it falls in those of higher specific gravity as low as 26 per cent., and in the "leaf" oil practically nil.

The percentage of eugenol in the pure "bark" oils, Nos. 1, 2, and 4, under notice varies from 4 to 71, the alcoholic solution of the oils becoming distinctly green with ferric chloride. The leaf oils examined contain from 80 to 90 per cent. of eugenol, the two samples under notice yielding 86 and 89.5 respectively, whilst Nos. 5, 6, and 7 contain from 82 to 86 per cent., and give well-marked reaction for eugenol with ferric chloride.

The optical rotation of the pure oils is practically nil, but as the leaf oils examined are dextro-rotatory, the fact that Nos. 5, 6, and 7 are slightly dextro-rotatory tends to confirm all the other considerations which point to the admixture with leaf oil to the extent of at least 80 per cent.

The above results are indicated in the following table.

From the above the following characters and tests seem to enable us to fix a new British Pharmacopoeia.

Specific gravity—At 15°C. 1.024-1.030
Optically inactive
One drop of the oil in 5 drops of rectified spirit should not give more than a pale green coloration. Oil should not solidify with a solution of caustic potash.

When treated with solution of chloral in solution of caustic potash, or of soda solution of triphenylmethane (Zeeb's test), it should not yield more than 45 per cent. of non-aldehydes, equal to 55 per cent. of cinnamon aldehyde.

Citrone Oil.—Although not official in any of the pharmacopoeias, this oil is one which the druggist handles for various purposes in large quantities, and in consequence it seems desirable to call attention to the chief characteristics of it.

In a paper by the author (Ph. J. [3], xxx, 922), attention was called to the fact that the normal colour of the oil was yellow, and the green coloration becoming usually more intense on warming or exposure to sunlight, was due to the presence of traces of copper. Of the eight samples examined and then reported on, only one was found to be adulterated. During the last few years, however, the price of the oil has fallen considerably, and the sophistication has increased to such an extent that it is only with difficulty that a genuine oil is obtained. The oil should be soluble in alcohol of 80 per cent. strength, and this, together with the specific gravity, affords indications of the purity or otherwise of the oil, without rendering fractionation necessary. A pure oil should dissolve in ten times its volume of spirits of that strength, and the specific gravity should not fall below .887 at 15°C.

Sohmmel and Co. stated (Ph. J. [3], xx, 264) that the gravity should not fall below .896 at 15°C, which is that of a sample distilled by themselves from dried grass, but no sophistication was detected in two of the samples examined and reported on in the above-mentioned note, which had a specific gravity of .887 and .890 respectively at that temperature. Recently (October, 1894), however, this firm announce that they have examined two samples of the oil having a specific gravity of .887 and .891 respectively, which were of good quality and unadulterated, thus confirming my observation previously recorded. The pure oil should therefore possess a specific gravity of not less than .887, and be soluble in ten parts of alcohol of 80 per cent. strength.

Clove Oil.—The specific gravity of this oil is variously stated by different authorities, the range of figures being from 1.041 to 1.067. The figures adopted by the United States Pharmacopoeia are from 1.069 to 1.067, and the German Pharmacopoeia 1.08.

The reason of this wide difference in recorded observations is due to the varying proportions of eugenol and the sesquiterpene caryophyllene.

Samples of oil distilled in Seychelles from fruit and stems in different conditions were examined, with the following result:—

Many samples of English distillation from dried cloves are found of lower specific gravity than those above recorded, the lowest examined being 1.0518, the highest being a re-distilled sample which had a specific gravity of 1.064.

It may be noted that the specific gravity of pure eugenol is stated by various workers to be from 1.068 to 1.070 at 15°C, whilst that of the sesquiterpene caryophyllene is assigned specific gravities between 0.964 and 0.910 at 14 and 15°C. I find that pure eugenol has a specific gravity of 1.068 at 15°C, but the sesquiterpene I have separated has a specific gravity of only 0.9331 at 15°C.

The process suggested by Thomas for the estimation of eugenol (see abstract PA. J., 3, xxi, 461), which consists in the formation of benzoyl-eugenol by means of benzoyl chloride, yields lower results than the specific gravities calculated from the amount of eugenol found would indicate and lead the author of that process to suggest that besides eugenol and the sesquiterpene, oil of cloves may contain a third body which may explain the varying relation between specific gravity and contents of eugenol. Thomas' process is open to objection both on account of the correction needed, viz., 7 to 8 per cent. for the solubility of benzoyl-eugenol in alcohol, as well as its volatility in the presence of traces of alcohol, although results concordant with one another may be obtained by the process.

A simple means which I have adopted for the estimation of eugenol consists in treating in a flask with long graduated neck, such as that suggested for cassia oil estimation, a definite quantity of the oil with 10 per cent. aqueous solution of caustic potash, warming the mixture, allowing the uncombined portion to rise, and measuring this portion at a temperature of 15°C. The difference being taken as the approximate percentage of eugenol. Three samples estimated in this way show the following result:—

<table>
<thead>
<tr>
<th>Found by</th>
<th>Found by</th>

<td>89 p.c.</td>
</tr>
<tr>
<td>From stems ……1.4051... 76.32 p.c.</td>
<td>88.5 p.c.</td>
</tr>
</tbody>
</table>

The percentages obtained by the process require slight correction for the difference in specific gravity of the two constituents, but correspond closely with the calculated proportions of constituents, and make it improbable that a third body (other than traces of vanillin) exists in the oil.

It is not suggested that this method would be applicable to other engenol-containing oils, in which esters and bodies other than terpenes or sesquiterpenes are present.

The optical rotation of the oils examined vary between —0.25 and —0.75 in a tube of 100 Mm., whilst all the oils examined distill within a very narrow limit above 247°C.

I have only examined one adulterated sample of clove oil, this one possessing a specific gravity of 0.9865 at 15°C, and containing a considerable proportion boiling below 85°C, consisting principally of alcohol.

The following appear to be the characters of pure clove oil, and are suggested for inclusion in a new British Pharmacopoeia:—

Specific gravity.—Not below 1.050 at 15°C.
Optical rotation.—Not more than —1°0 in 100 Mm. tube.

When treated by the process described above, vis., ammonification, with 10 per cent. potash solution, not more than 15 per cent. should remain uncombined, equal to 85 per cent. of eugenol.

No portion of the oil should distill below 247°C.

Copaiba Oil.—A comparison of the essential oils distilled from the two principal commercial varieties of Copaiba has already been published by the author in a paper on “So-called African Copaiba” (PA. J., September 9, 1893). The oils of the South American varieties show but slight differences, the specific gravities and solubilities in various solvents being practically identical, while the boiling points show but slight variation. The oil from the African oleo-resin, the botanical source of which, though possibly an African species of Copaifera, has not been definitely determined, is dextrorotatory, of higher specific gravity, and much less soluble in absolute alcohol.

The following abridged table of results clearly indicates these differences, it being hardly necessary to point out that the oil usually met with in commerce is derived from Para oleo-resin, in consequence of the larger proportion of essential oil contained therein.

<table>

</tr>
</tbody>
</table>

The experiments of H. Hurry Fenwick, F.R.C.S., with the African oil, although proving it to be of a similar action to the oils of the South American varieties, do not warrant the recommendation of its inclusion in the new B.F., more especially as its botanical source is not determined and its import up to the present irregular.

The new British Pharmacopoeia might require that the oil should be levorotatory, have a specific gravity of 0.900 to 0.910 at 15°C, and be soluble in its own volume of absolute alcohol.

Cubeb Oils.—This oil, which is official in the United States as well as the British pharmacopoeias, is not largely used, but is nevertheless of chemical interest. The oil is now so cheap as to render sophistication unlikely, but cubebes are subject to great market fluctuations, the prices recently being almost the lowest during the present generation.

The oils examined of English distillation have a bluish-green coloration which is due to the presence of a blue oil possibly similar to that contained in chamomile and Japanese valerian oils, which is more marked in the highest fractions on distillation.

The specific gravity of the oils examined vary between 0.910 and 0.926 at 15°C, a typical English sample, freshly distilled, possessed the following characters:—

Specific gravity.—0.9222 at 15°C.
Rotation.——8°30' in a tube of 100 Mm.
Fractionation... 175°-250° ...... 9.2 per cent.
250°-260° ...... 26.8 "
260°-270° ...... 47.6 "
270°-280° ...... 7.2 "
Above 280° ...... 2.2 "

The composition of the higher fractions 260°-280° C. of the oil is interesting, as the presence of two sesquiterpenes are indicated, the hydrate of one of which is the so-called cubeb camphor.

The solubility of the oils in alcohol of 90 per cent. strength varies considerably, the sample under notice not being readily solubile even in twice its volume, several examined, however, answer the U.S. Pharmacopoeia requirements that they shall dissolve in an equal volume of that solvent. The test appears, however, somewhat stringent, and an oil that answers the following may be considered as of good quality:—

Specific gravity.—910-930 at 15° C.

At least 70 per cent. of the oil distils between 250° C. and 280° C.

(To be continued.)

Correspondence.

THE ATOMIC THEORY.

Sir,—In your last week's issue your correspondent, Mr. Alexander Laing, petitions your aid in the "sitting upon," "massacre," and "dissipation" of the atomic theory when used as fact. So bold a request manifestly argues not only insufficient grounds for the rejection of so fundamental a theory, but that the petitioner possesses an intimate knowledge of the subject. Now the rejection of the theory must consist of ultimate indivisible particles called atoms, which implies that matter, like time, space, and number, is infinitely divisible, and that such infinite divisibility is possible is universally agreed by philosophers—the "knowledge" of the infinitely applying to the Deity alone. But what is possible and what exists is a very different affair, and the facts which support the atomic theory are as follows:—"If a substance A unites with another B in several proportions, then the masses of B which unite with one and the same mass of A always stand in simple ratios to each other," and this is no less than Dalton's law. Before the proposed massacre commences, Mr. Laing will perhaps kindly tell us what he knows about infinity as applied to matter.

University College Hospital. Wm. Elsberg.

Sir,—The application to atoms and molecules of the principle of gravitation which obtains amongst stars and systems is an applied fact. Atoms and stars are all immersed in the infinite ocean of ether, the waves of which, lashing them together, is the principle of gravitation, whose various phases depend upon how bodies more or less shield each other from the general surge. Witness air bubbles floating on the surface of water in a basin. If they remain far apart they may remain apart long enough, but bring them near to about an eighth of an inch from each other and then suddenly they gravitate together or combine. Why? Because the sides that are facing each other are shielded from the general pressure forces which are beating all round on the outer exposed sides, and the air bubbles are forced together. There is a class of people still extant who in the face of applied sciences declare that the earth is not a globe, but a flat plain. Such a class of people are branded as "the flate." Let us beware then how we treat the above atomic gravitation law, lest in rejecting it we also be branded "flaters."

Glasgow.

* The fact of the publication of the above letter must not be taken to imply that it is considered desirable to discuss the truth or otherwise of the atomic theory or the principle of gravitation in our columns. They are both too generally accepted nowadays to be affected by anything that may appear in a journal of pharmacy, and learned though its correspondents may be.—[Ed. Pharm. Journ.]
Notes and News.

EVENING MEETING IN EDINBURGH.—The list of communications to the meeting of the Pharmaceutical Society at York Place, Edinburgh, on Friday evening, has been somewhat amplified since the announcement last week, the first place on the list being taken by Mr. James Mackenzie, F.S.A. (Scot.), who contributes an interesting lid paragraph containing the articles of association of the Society of Druggist Apothecaries in Edinburgh. This society was formed in 1785, and, though there seems to be no record of it in history, the document appears to be undoubtedly genuine. Another addition to the list is a paper on the "Legalisation of Metric Weights and Measures," by George Loun.

PHARMACEUTICAL CONFERENCE AT LIVERPOOL.—According to the Liverpool Mercury it is proposed to invite the British Pharmaceutical Conference to meet in Liverpool next year, when the British Association also meets in that city, and at the meeting of the Liverpool Chemists' Association on Thursday, a resolution would be proposed to carry the idea into effect and to appoint a committee to make the necessary arrangements.

PHARMACEUTICAL EXAMINATIONS IN JAPAN.—At the two examinations for pharmacists held in Tokio and Osaka, Japan, during 1891—particulars of which appear in the Annual Report, quite recently published, of the Central Sanitary Bureau attached to the Home Department of the Imperial Japanese Government—33 out of 166 candidates passed on the first occasion, and 36 out of 193 on the second. To prevent personation at the examinations each candidate is expected to write his own application for examination, and to let his photograph, taken during the same or previous year, accompany the written application. The number of pharmacists licensed during the year was 25, of whom 14 passed the examination, whilst 9 were graduates of the Imperial University. Altogether there were 2692 pharmacists, 11,849 druggists, and 1336 manufacturers of medicine in Japan, at the end of 1891.

ADULTERATION OF DRUGS IN ILLINOIS.—A Bill recently introduced into the Senate of Illinois is entitled, "An Act to prevent and punish the Adulteration of Drugs, Food, Drinks, or Confectionery." It proposes that the term "drug" shall include "all medicines for internal and external use, antiseptics, disinfectants, and cosmetics," and that the U.S. Pharmacopoeia shall be the standard for all articles named in it, whilst the standard for others shall be any pharmacopoeia or standard work on materia medica wherein the drugs are named. The Bill is likely to be opposed by Illinois pharmacists.

REPORT OF THE OPTUM COMMISSION.—The Times thinks the delay in the publication of this report (see p. 987), is not altogether to be regretted, since it has allowed time for the publication of the results of the inquiry into the use of hemp drugs (ante, p. 929). The result of the two inquiries proves beyond doubt that neither opium nor ganja operates as a cause of disease, insanity, or crime among the Indian population.

ANIMALS IN STERILISED AIR.—By keeping animals in a specially devised apparatus designed to supply them with air in an absolutely sterilised condition, and also feeding them with food as far as possible free from bacteria, Dr. J. Kijncsen, of the University of Kiev, has been able to ascertain that there was a remarkable decrease in their assimilation of nitrogenous matter. The reason suggested is that micro-organisms, when present, aid in the decomposition and putrefaction of the nitrogenous matter in the intestine, and it is thought that were the removal of all the micro-organisms from the intestine possible, the decrease in the assimilation of nitrogen would be still greater. The animals also lost weight more quickly than under normal conditions, and excreted more nitrogen and carbon dioxide. In a number of cases the animals died a few minutes, hours, or days after the beginning of the experiment, and as yet it has not been possible to assign any cause for this result.

SIR JOSEPH LISTER AND THE ABERDEEN MEDAL.—The Albert medal of the Society of Arts was presented to Sir Joseph Lister, Bart., F.R.S., on Tuesday, April 9, by the Prince of Wales. It has been awarded to him for the discovery and establishment of the antiseptic method of treating wounds and injuries. Sir Joseph is the President-elect of the British Association for the meeting at Liverpool in 1896.

BRITISH MEDICAL ASSOCIATION ANNUAL MUSEUM.—In connection with the sixty-third meeting of the British Medical Association, which will be held in London, this museum will comprise the following sections:—A.—Drugs and foods, including chemical and pharmaceutical preparations, prepared foods, etc.; B.—Instruments, comprising medical and surgical instruments and appliances, electrical instruments, microscopes, etc.; C.—Books, including diagrams, charts, etc.; D.—Sanitary and ambulance appliances. The space allotted to the Annual Museum at the Examination Hall on the Victoria Embankment includes the whole of the first floor. The sectional meetings in medicine, surgery, psychology, pathology, bacteriology, laryngology, pharmacology, and therapeutics, will probably be held in other rooms in the building. A limited number of small rooms in King's College, where the following sectional meetings will probably be held:—obstetrics, anatomy and physiology, ophthalmology, diseases of children, otology, and ethics, are also available for separate exhibitors at special rates. The terrace at King's College has been placed at the disposal of the Committee for the exhibition of sanitary and ambulance appliances. All communications on general matters connected with the museum, and all applications for space, with a brief description of the exhibit, should be addressed to Dr. Oswald, 11, Chandos Street, Cavendish Square, before June 1. The Committee will allot the space as early as possible after that date.
ANTI-STREPTOCOCCUS SERUM.—The truth respecting M. Marmorek’s discovery, recently referred to (ante, p. 881), appears to be that he has prepared a serum which he claims to possess curative and prophylactic properties in connection with the numerous diseases associated with Streptococcus pyogenes. The cases experimented with were those of persons affected with puerperal fever and erysipelas, and extremely favourable results have been obtained so far.

DIPHTHERIA ANTITOXIN IN RUSSIA.—It is found in Russia that the extreme cold which prevails for so long a period causes Behring’s antitoxic serum to lose part of its antitoxic properties, a quantity one and a half times greater than the maximum dose falling to neutralise a minimum fatal dose of diphtheria toxin. On the other hand, a serum prepared at the Moscow Bacteriological Institute suffered no ill-effects from exposure to cold, and in some experiments even appeared to have acquired stronger antitoxic properties.

CAMPHOR IN CALIFORNIA.—The New York correspondent of the Lancet states that an effort is being made to grow the camphor tree in California, with a view to replacing Formosa camphor by a native product.

GROCERS’ COMPANY MEDICAL RESEARCH SCHOLARSHIPS.—These scholarships, three in number, are each of the value of £250, and open only to British subjects. They have been instituted by the Grocers’ Company as an encouragement to the making of exact researches into the causes and prevention of important diseases, and the appointees are made annually, and the holders of the scholarships are entitled to preference in making future appointments. Applications for the current year should be made before the end of April to the clerk of the Grocers’ Company, Grocers’ Hall, Princess Street, E.C.

HELIUM FROM CLEVEITE.—As previously mentioned in the Journal (Epit. p. 111) Professor Ramsay has obtained from the mineral Cleveite argon mixed with helium. Professor Cleve, of Upsala, after whom the mineral is named, has since stated that specimens of it examined in his laboratory gave off a gas which did not contain any trace of argon. Examination of the spectrum revealed an exact coincidence of the line of the gas with the helium line, and an experiment to determine the specific gravity seemed to indicate that the gas is heavier than hydrogen. J. N. Lockyer announces in Nature that he has also failed to detect argon in the gases given off from Cleveite, on heating in vacuo, but he finds hydrogen associated with the new gas.

Proceedings under the Pharmacy Act.

SALE OF FELLOWS’ SYRUP BY UNREGISTERED PERSONS.

At the Carnarvon County Court, on April 17, his Honour, Sir Horatio Lloyd, delivered judgment in an action heard at the last Court, in which the Pharmaceutical Society of Great Britain appeared as plaintiffs and Messrs. Evans and Lake, grocers, Carnarvon, as defendants (ante, p. 116). The action was brought to recover £5, being the amount of penalty alleged to have been incurred by the defendants on January 2, 1895, by selling or keeping open a shop for the restocking, dispensing, or compounding of poison contained in “Fellows’ Syrup of Hypophosphites,” a preparation of strychnine, contrary to the provisions of the Pharmacy Act, 1886. His Honour said that it appeared that Mr. T. J. Hughes, a registered chemist at Betheas, having reason to suppose that unauthorised persons were selling this compound, went to the defendants’ shop on January 2 and purchased a bottle of “Fellows’ syrup.” Mr. Garner and Mr. Hughes, the assistants, denied having sold the compound, their evidence, to his mind, could not prevail against the positive testimony of Mr. Hughes, because, finding that the names of Messrs. Evans and Lake were not on the bottle he bought a pennyworth of Virtue’s toilet soap, which was packed in a bag with the firm’s name, at the same time. At present he could not believe that Mr. Hughes was such a wicked person as to concoct the story. As a registered chemist of course he had an interest in the matter, but he had no reason to doubt that he was telling the truth. He had come to the conclusion that Hughes did buy the bottle there which contained strychnine. On the point of law raised as to “selling” and “keeping an open shop,” his Honour also decided against the defendants. However, it was only right towards Messrs. Evans and Lake to say that he believed in their bond fides. Having seen Fellows’ syrup in the list of goods not to be sold by unregistered persons, they no doubt did intend to withdraw the syrup from sale, but he was afraid that it was one of those good intentions which were not carried out. He gave judgment for the plaintiffs, with costs.—In reply to Mr. J. T. Roberts, his Honour said that he could not allow an appeal on the decision (of law, but on point of law, a point in point, at month, in order to give defendants an opportunity of deciding whether they would apply for a new trial or not.

SALE OF POISON BY AN UNQUALIFIED ASSISTANT.

At the County Court, Newcastle-on-Tyne, on Monday, April 22, before His Honour Judge Greenwell, the Pharmaceutical Society of Great Britain brought an action against Ernest Fleming, chemist’s assistant, to recover £5, the penalty incurred by him for having on December 31, 1894, contrary to the provisions of the Pharmacy Act, 1868, sold a certain poison, namely, morphine, contained in the proprietary medicine known as Dr. Collins Brown’s chlorodyne. Mr. T. B. Grey, barrister-at-law, London, appeared for the plaintiff Society, and Mr. Edward Clark, solicitor, Newcastle, defended.

Mr. Grey said the defendant was an assistant in the employ of Mr. Davidson, chemist and druggist, of 114, Westgate Road, Newcastle. Defendant was not a chemist qualified under the Pharmacy Act to sell poisons, and he, notwithstanding that, and not being under the supervision of his qualified employer, did sell on December 31 last, to a witness who would be called, a bottle of Dr. Collins Brown’s chlorodyne. The chlorodyne had been analysed, and he would call the analyst to prove that it contained morphine, which was a poison under the Act, to the extent of 1 grain. The defendant by his action had rendered himself
Hable to a penalty of £5. Mr. Grey then referred his Honour to the judgments in the "Piper" and "Wheeldon" cases, which completely covered the ground of the present action.

Mr. Clark, in reply, said he must admit all the facts. His client was the unqualified apprentice of a chemist and druggist, he had no right to sell poisons, and he had sold this article. The bottle was, furthermore, labelled poison, and the defendant could only plead that he sold it under the impression that it was a patent medicine. He (Mr. Clark), from a perusal of the judgment against Piper in the case quoted by Mr. Grey, was satisfied that the article was not a patent medicine. He was there in order that full publicity might be given to the facts, and he hoped the Press would publish the case so that people might be informed that a chemist's apprentice was not bound to sell them any article that might be in his employer's shop.

His Honour: He is absolutely prohibited from selling poisons.

Mr. Clark further stated that his client had received no instructions from his master not to sell poisons, and he also thought that it was the duty of the master, who could not be got at under this section, to look away these poisons from his unqualified-assistant.

His Honour said he thought that the best chemists did not let their apprentices not to sell poisons, except under their direct supervision.

Judgment was given for the plaintiffs for £5 and costs.

Miscellaneous News.

[Readers are invited to send local information of pharmaceutical interest. When newspapers are sent the paragraphs to be noted should be plainly marked, whilst the same should be verified by the addition of source and date.]

SALE OF DEFICIENT LIQUOR IODI.—At the North London Police Court, on April 18, John Dwyer, chemist, of 125, Balls Pond Road, Islington, was summoned by the Vestry of Islington for selling liquor iodii showing a deficiency of 46.2 per cent. of iodine and a slight deficiency in potash. On the facts of the defence, submitted that the last clause of the indictment was too indefinite to be dealt with, and the prosecution consented to its being withdrawn. It appeared in evidence that Dr. Harris, Medical Officer of Health for Islington, sent an inspector to purchase 6 oz. of liquor iodii, for which his supervisor demanded 2s., and on analysis this proved to be deficient in strength. The defence was that sufficient time was not given for the iodine to be dissolved. The Inspector was served within ten minutes, whilst it would take hours for the crystals to be dissolved. Defendant told the inspector so, notwithstanding which the inspector divided the 6 oz. into three portions, and took one portion for analysis.—Dr. Harris was called, and said that if sufficient distilled water to simply cover the iodide, and iodide of potassium were added they would dissolve in a quarter of an hour.—Defendant's case was that having added the bulk of the water to facilitate the dispensing of the prescription, the iodine was so much longer in dissolving. He made up the prescription according to the Pharmacopoea, and after the inspector had taken his sample from the 6 oz. bottle for analysis there still remained some of the undissolved crystals in the bottle. The 6 oz. bottle was taken away, and had been knocking about the Vestry Hall for some weeks unsealed, and consequently, owing to the volatile nature of the drug, the crystals had disappeared, and there was not much use in submitting it to analysis.—Mr. Lenn suggested that the third portion of the sample and what was left in the 6 oz. bottle should be sent to Somerset House, but Mr. V. Yarborough, on behalf of the defendant, said that, considering the expense of further analysis, he would consent to a fine of £1.5 and 5 guineas costs.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.—The annual supper took place in the Impregnable Hotel, Market Street, on Friday, April 19, when about fifty persons. Mr. Alexander Sutherland, President, occupied the chair, and was supported by Mr. J. Laidlaw Ewing, Chairman of the North British Branch Executive, and Mr. Peter Boe, Chairman of the Edinburgh District Chemists' Trade Association; Messrs. J. M. Cameron and J. McBlain acted as croupiers. Apologies were intimated from Messrs. D. Storrr, Kirkcaldy; T. Maben, Hawick; J. Lothian and D. Macalister. The loyal toasts having been duly honoured, Mr. W. B. Cowie proposed "The Pharmaceutical Society," which was acknowledged by Mr. J. Laidlaw Ewing. Mr. W. Duncan proposed "The Edinburgh District Chemists' Trade Association," which was acknowledged by Mr. P. Boe. In the absence of Mr. Storrr, Mr. J. Laidlaw Ewing proposed "The Edinburgh Chemists', Assistants', and Apprentices' Association," which was acknowledged by the Chairman. In the absence of Mr. D. Maclaren, Mr. Thwaites proposed "The Edinburgh Pharmaceutical Athletic Club," which was acknowledged by the Vice-President, Mr. W. B. Cowie. Mr. Dey proposed "The Ladies," which was acknowledged by Mr. Hill. An excellent musical programme was provided by Messrs. W. Duncan, J. P. Gibb, Thwaites, C. Brown, J. Chrichton, Robertson, A. Murdoch, R. H. Tweedie, R. Bethchart, J. Brown, and J. M. Cameron; Mr. James Chrichton acting as accompanist.

CHILDREN POISONED BY AN EYE LOTION.—On Monday, April 16, some children were playing near the railway embankment, Hollinwood, when one of them found a small bottle containing a dark coloured mixture, Thinking it was "Spanish juice," she drank part of the contents, and then handed the bottle to four other children, who all drank of it. Some time after they were all seized with drowsiness, and complained of feeling ill. During the night the following day the children became ill and on the Wednesday morning they were slightly better, though by no means thoroughly recovered. It has since been ascertained that the bottle contained a strong poison, used as an eye lotion, and it is supposed that some careless passenger on the railway had thrown it out of the carriage window.

DEATH UNDER CHLOROFORM.—At an inquest held at Stockport on April 20 on the body of James Swindells, aged 15, of Gee Cross, Cheshire, it was stated that he had been removed to Stockport Infirmary after being kicked on the leg. It was found necessary to perform an operation to remove a dead bone, and he was chloroformed, but died whilst under the influence of the anaesthetic. The jury returned a verdict of misadventure, adding that the chloroform was properly administered.

POISONED BY BROTH.—An inquest was held at Lisadream, near Newry, on April 20, on the bodies of Samuel and James Moffitt, who had died in great agony, apparently from the effects of poison. Mrs. Moffitt stated that she made some broth on Sunday of beans and barley, and that what was left was eaten for dinner on Monday. After dinner the whole family became ill, and her two sons died. The medical evidence showed that the broth had fermented and caused cholera diarrhoea, and the jury returned a verdict accordingly.
PHARMACEUTICAL]

MISCELLANEOUS NEWS. [APRIL 27, 1895

THE GERMAN ELECTRO-CHEMICAL SOCIETY.—According to the Electrical Review, this new society, the object of which is the development of electrochemistry in its scientific, technical, and economic aspects, has started work under very favourable auspices. The enthusiasm which the idea of electrochemistry has been highly encouraging. The first meeting was recently held at Berlin, when Professor W. Ostwald read a paper upon the researches of J. W. Ritter, a contemporary of Galvani and Volta, who was the first to perceive that Volta’s electro-chemical arrangement was analogous to the muscles corresponded to the order of their affinity for oxygen. The researches of the late Sir William Crookes have also been communicated by Dr. O. Frohlich on the practical applications of ozone. This gas has been introduced in Germany into many different branches of industry, the most important of which are, so far, bleaching, the maturing of spirits, tobacco and coffee, and the ageing of wood, especially in its application to the sounding boards of pianofortes. Amongst other branches of industry in which ozone is now being successfully employed are the thickening of linseed oil, which, in the linseed factories is brought about by allowing it to trickle over strips of gauze for several months; the use of ozone, however, affects the purpose in a few days. Dr. Frohlich dwelt, as might have been expected, with considerable detail upon a process for converting crude potato starch into the soluble variety (a very important operation to the distiller), as well as into dextrin and other gummy substances, by means of ozone. He hopes shortly to accomplish the production of nitric acid from the air by means of ozone. In this he is wished more abundant success than he is likely to realise. It has long been a favourite dream amongst chemists, and if it could be done economically, would probably be adopted in the production of this most useful acid. The atmosphere contains all the constituents necessary for manufacturing nitric acid, viz., water, nitrogen, and oxygen, and without being very sanguine that Dr. Frohlich will succeed, there is every prima facie reason why he should. If he does it will be another triumph for electricity. The new German society has begun uncommonly well; there is certainly room for it, and it may be wished a successful future.

PRESCRIBING BY A CHEMIST.—On April 17 Dr. Wynn Westcott held an inquiry at Bethnal Green Vestry Hall concerning the death of Alfred Wiggs, aged three years, the son of a painter, of Tent Street, Bethnal Green. Jane Wiggs, the mother, deposed that she had not sent the child to the chemist for medicine, and the chemist had prescribed it for bronchitis. She procured threepennyworth of mixture at “Dr.” Lacy’s, in the Whitechapel Road, a chemist’s shop, but the child became worse, and witness then procured a powder from another chemist and gave it to the child. At midnight it was seized with a fit, and witness himself attempted to resuscitate the child. He refused to attend without a fee of 5s. Death ensued on the Sunday morning about four o’clock. Dr. Quillinan stated that death was due to pneumonia and pleurisy. The child must have been seriously ill for many days.

The coroner, addressing the mother, said that a chemist was taught to weigh up and sell medicine, but it was a great mistake to suppose he could give proper medicine for anyone merely on the symptoms being described to him. He was not supposed to know how to treat diseases, and the mother might just as well have asked her butcher to prescribe. A verdict of “Natural Death” was returned.

DRUG CONTRACTING FOR THE POOR.—A correspondent of the Southampton Times points out that one of the most prominent features of the “drug tender form” is that the British Pharmacopoeia (B.P.) is to be taken as the standard. Tests of purity, etc., are therein contained, and need only to be applied to find out impurities and adulterations. Yet, in the face of this, one finds throughout this model document the word (sometimes in English and sometimes in Latin) “pure,” and in addition “B.P.” He asks if a preparation is allowed to be given at all it must be “pure.” Another prominent feature is that the bulk of the standard preparations are to be by special makers, thus preventing the contractor who manufactures from supplying, although he makes according to the standard (B.P.) laid down, and by which all chemists are bound by law to do, or render themselves liable to be prosecuted under the Food and Drugs Act. One item which strikes the eye is ‘distilled water’ (followed by the name of a local firm), thus compelling the contractor to buy an article in daily use by every chemist from one firm, even though they may make it themselves. Again, ‘solution of morphine,’ which is made available at a price here ordered to be of a certain London make. ‘Morphine hydrochlorate, pure, B.P. standard strength.’ What does it mean? B.P. indicates the purity, and also standard strength. What other standard is necessary? Next, ‘oleum morrhuae pale non-congealable, select, opt. nov.’, etc. (translated cod-liver oil pale un-congealable, chosen, best, new). Further down, ‘oleum jecoris aselli nov.B.P.specia’ (translated cod-liver oil, new British Pharmacopoeia special). In each case a so-called maker’s name follows, and both different, exhibiting an ignorance which one would not expect from a twelvemonth’s apprenticeship. Firstly both articles are the same, under the new and old names. Secondly, I take it that neither of the makers named are makers at all. But chemists are asked to tender for the same article labelled differently, and in all probability the oil is from the same manufacturer, and any buyer of quantity can procure from the standard sources as these London makes. Next, ‘novum Ferris.’ Now this is a registered name, and been in use for many years, and only made by ‘Ferris,’ so that this is useless and gratuitous information. Next, ‘unguentum sinal cridi benzoated, B.P.‘ If it is B.P. it must be benzoated. Again, oils of peppermint, ‘Hotchkius, H. G.’ (a well-known American brand) is to be bought from a London distiller. What nonsense!
This article is placed on the open market. Another joke is 'plumbi acetas, Ang.' (English). Will this responsible person state what special part of England it is to come from? It is an insult to an educated body of men to ask them to contract on speculation. The specially alarming of the poison is no longer appearing on ordinary drugs and preparations made by most chemists, and by every manufacturing chemist, is as bad as insisting on the hay being supplied from a special farm, and placed in sealed bags, branded with the name of the farmer, because the reaper whose duty it is to reap is in behalf of the Corporation cannot judge of its quality.

REPORT OF THE OPIUM COMMISSION.—A summary of the report of the Royal Commission on Opium was issued this week. The Commissioners, by a majority of eight against one, report in favour of the continuation of opium cultivation under present conditions, and come to the conclusion that “it has not been shown to be necessary or to be demanded by the people that the growth of the poppy and the manufacture and sale of opium in British India should be prohibited except for medical purposes.” As to the moral and physical effects of the drug on the consumer, its excessive use has many evil results, but, say the Commissioners, “in every part of India with which we had to deal, we found witness after witness testifying to the belief in opium as the common domestic medicine of the people. It is taken in cases of specific disorders, such as rheumatism, diabetes, chill, and diarrhœa. It is regularly administered to unweaned children. In malarial and damp tracts there is general faith in its virtue, either in warding off or in curing fever.” They find a preponderance of evidence that the use of opium in India is moderate, and leaves no evil effects; and they say, “excess is exceptional, and condemned by public opinion.” Native opinion is entirely opposed to prohibition, and the Europeans in India are on the whole strenuously opposed to it, while the Protected States could not be included in prohibition and would get the trade abandoned by the British provinces. Smoking is regarded as a disreputable use of the drug, and legislation against smoking saloons and clubs might not be viewed with disfavour. As to the existing treaties with China with regard to the importation of Indian opium into that country the Chinese Government has formally admitted that it is satisfied, so that no commission is required to represent that there is no surplus of opium to take any steps in the matter on behalf of China. Mr. Henry J. Wilson, M.P., the single dissentient, gives instances which he regards as proving that the authorities took up a partisan attitude, and “seemed determined that no evidence should be submitted to the Commission which had not been subjected to official scrutiny in high quarters.” He contends that “whatever the Government of India intended, by their determination not to seek for evidence of an anti-opium character, its action was likely to be understood, and was undoubtedly understood, to mean that pro-opium evidence was to be sought for, and anti-opium evidence was not.” Apart from these complaints as to the partiality of the inquiry, Mr. Wilson thinks the growth of the poppy and the manufacture and sale of opium should be prohibited except for medicinal purposes, and that the poppy culture should be entirely forbidden, and licences for cultivation are refused, licences for transit from Native States, except for medical purposes, should be withheld, and that official vendors should be appointed, with instructions to restrict the sale. He recommends the entire prohibition of opium smoking, and adds, “The whole case appears to me to partake more of the character of an elaborate defence of the opium trade of the East India Company, and of the present Government of India, than of a judicial pronouncement on the immediate questions submitted to us.”

THE SALE OF ABSINTH IN INDIA.—The last report of the Chemical Examiner in Burma is said to supply additional evidence in favour of the proposals made to the Indian Medical Congress by Surgeon-Captain Evans for restricting the sale of absinthe. Out of twenty-five cases of poisoning brought to notice last year fifteen were cases of absinthe poisoning.

THE DEATH OF MR. G. W. SARGENT.—Dr. Stevenson, the official analyst to the Home Office, having completed his report in connection with the sudden death of Mr. G. W. Sargent, chemist and druggist, of South Kensington, who was found lying unconscious behind his counter, and died at St. George’s Hospital, it was presented at the adjourned inquest on April 20. It stated that the death of Mr. Sargent was due to poisoning by morphine, and the jury returned a verdict to the effect that death was due to morphine poisoning, but how it was administered there was no evidence to show.

ACCIDENT TO DR. STEVENS.—On Saturday, April 20, Dr. Thomas Stevenson, the official analyst to the Home Office and Government Visitor at the Pharmaceutical Society’s examinations, was thrown out of his cab in Buckingham Palace Road while proceeding to the Westminster Coroner’s court to give evidence in connection with a case of death from poisoning by morphine. The accident was caused by the horse suddenly falling down, but happily the occupant of the cab received nothing worse than a severe shaking and one or two bruises, and was able to proceed to his destination without delay.

Poisoning Cases and Inquests.

Tincture of Opium.—Edward King, a publican, was found dead on Wednesday, April 17, on Wandsworth Common, having died from the effects of tincture of opium, self-administered. Verdict: “Suicide during insanity.”

Carbolic Acid.—William Hessey, aged 45, died on Wednesday, April 17, at the Stanley Hospital, Liverpool, from the effects of carbolic acid, self-administered. Verdict: “Suicide whilst in a state of temporary insanity.”

Strychnine.—Robert Rawsthorne, a publican, died on Thursday, April 16, at Bolton, from the effects of strychnine.

Oxalic Acid.—Alice Reay, aged 22, died on Wednesday, April 17, at 44, Union Street, Walsall, from the effects of oxalic acid poisoning. Verdict: “Suicide whilst temporarily insane.”

Sulphuric Acid.—Alice Reay, aged 22, died on Wednesday, April 17, at 44, Union Street, Walsall, from the effects of sulphuric acid, self-administered. Verdict: “Suicide during temporary insanity.”

Prussic Acid.—G. A. Drew, aged 58, a veterinary surgeon, died on Wednesday, April 17, at Abington, from the effects of prussic acid, self-administered. Verdict: “Suicide whilst of unsound mind.”

Luadanum.—Alexander Patterson, died on Sunday, April 21, at 33, Gate Street, Swinton, from the effects of luadanum. Verdict: “Death by misadventure.”
Obituary.

Notice has been received of the death of the following:—
On April 16, George Cheatham, Chemist and Druggist, Timperley. (Aged 82.)
On April 20, R. H. Kearns, Chemist and Druggist, Bilton. (Aged 63.) The deceased was at one time one of the most prominent tradesmen in Bilton, taking, as he did, a leading part in all public matters, and at the same time carrying on a very extensive wholesale and retail business as a chemist. For many years he was one of the directors of the Bilton Gas Company and a member of the Board of Guardians.
On April 21, William Darling, Pharmaceutical Chemist, Manchester. (Aged 82.) Mr. Darling was one of the Founders of the Pharmaceutical Society.
On April 21, Robert Owen Fitch, Chemist and Druggist, South Hackney. (Aged 65.) Mr. Fitch had been a member of the Pharmaceutical Society since 1860, and was the Society's divisional secretary for South Hackney.

Patent Office Business.

Applications for Patents.*

No. 7126.—Improved apparatus to facilitate the labelling of bottles and other vessels. April 8, 1895.
No. 7167.—Improvements in apparatus for pumping, raising, or elevating liquids, semi-solid substances, grain, or the like. April 18, 1895.
No. 7181.—Improvements in tooth cleaning devices. April 8, 1895.
No. 7214.—An improved liquid-measuring and draughting apparatus. April 19, 1895.
No. 7236.—Improvements in or connected with bottles and their closing means, with a view to preventing the refilling thereof. April 9, 1895.
No. 7282.—An antiseptic case for surgical instruments, combined with a sterilising apparatus. April 9, 1895.
No. 7297.—Improvements in separating fluids of different specific gravity and in apparatus therefor. April 9, 1895.
No. 7326.—Improvements in, and apparatus for sterilising liquids. April 9, 1895.
No. 7800.—Improvements in centrifugal machines for separating fluids of different densities. April 11, 1895.
No. 7433.—A new or improved medicinal appliance. April 19, 1895.
No. 7497.—A new apparatus for guzzling or moistening labels or other papers. April 18, 1895.
No. 7498.—New food preparations, liquid and solid, for animal food. April 19, 1895.

Patents Published April 20.

Extracting metals from ores (Thompson, W. P. Communicated from Bonehill, L. R., and Gaultier, E. T.).—The invention relates to a method and furnace for obtaining copper, lead, gold, silver, and other metals directly from the ore by a single operation. The ore, mixed with fuel, is fed into a furnace having an inclined bed, through an opening in the roof, and is subjected to a blast of air from a number of tuyeres in the vertical section of the furnace. The metal thus reduced flows towards an outlet in the furnace, the portion on the upper part of the bed being covered with the slag, but that at the lower portion being entirely exposed to the blast to "refine it." Suitable condensing chambers are provided for obtaining volatile products from the ore. No. 3138 of 1894.

Aerated beverages (Schwartz, J.).—Relates to private or coin-free or other vessels for supplying soda-water, etc., and comprises an arrangement in which water or other beverage supplied automatically or otherwise, is saturated with carbonic acid gas from one of the ordinary compressed-gas cylinders. The gas may be caused by bafflings, or other arrangement, to pass through the liquid, to ensure rapid saturation. The turning of the tap which draws off the aerated liquid may be arranged to admit an equal supply of the unsaturated liquid and a sufficiency of gas. No. 8464 of 1894.

Breast-pump (Lake, H. H., communicated from Golfer, A.).—The apparatus is made mainly of indiarubber, and forms a mouthpiece which is placed against the breast, while a suction apparatus consisting of an ordinary collapsible ball is operated to draw the milk from the nipple into a small reservoir. The mouthpiece contains a hollow ring connected with a collar or boss, and so shaped as to embrace the nipple. While the milk is being withdrawn, the last-named ball is alternately compressed and allowed to expand so that the nipple is constantly pressed and refused by the ring as by the lips of a child. No. 9747, A. 1894.

Softening water (Hooper, G. G., and Tyncke, F. H.).—Relates to the ordinary method in which lime-water is used. The apparatus is fitted with chambers in which the lime-water is produced from cream of lime; mixing arrangements in which, by means of a screw or other appliance, the requisite amount of lime-water and of the water to be softened are mixed; settling tanks in which the carbonate of lime is deposited, and a filter. The whole apparatus is fitted in an outer casing. No. 9614 of 1894.

Treatling gold and silver ores (Thompson, G.).—The ore, having been roasted if sulphurous, is treated in a retort, and subjected to the action of "hydrochloric acid or an alkaline chloride with sulphuric acid." The inventor states that the gold and silver are volatilised, probably as chlorides, and may be collected in towers or condensers. He has fitted in at least two condensers, one containing water which retains the gold, and the other containing dilute nitric acid which retains the silver. No. 10,349 of 1894.

Saturating liquids with gases (Beins, J. F.).—Comprises an apparatus in which water or other liquid may be saturated with carbonic acid gas, air, oxygen, ammonia, or other gas without the use of agitators, etc. It consists of an upper and a lower compartment, connected by a number of porous porcelain tubes which form the top of the lower compartment. The liquid to be treated is charged into the upper compartment, and the gas is supplied to both compartments, but at a higher pressure in the lower one. The liquid is thus forced through the porous tubes as spray and becomes saturated with the gas and may readily be drawn off from the lower compartment. Bottling arrangements are described by the inventor. No. 10,533 of 1894.

Trade Marks Applied For.*

No. 185,164.—Chemical Substances used for Agricultural, Horticultural, and Sanitary Purposes and Horse and Cattle Medicines, and Dressings includes 2.—Thomas Pink, St. John's Lane, Borough, London, January 13, 1895. A Bird of Paradise and the words "Paradise-bird Brand."

No. 184,996.—Instruments, Apparatus, and Con
tivances, not medicated, for surgical or curative purposes, or in relation to the health of men or animals, not being goods coming under sub-section 3 of section 38 of the Patents, Designs, and Trade Marks Acts, 1883, but not including vaccine, human or animal, and pin points, and not including any goods of a like kind to any of these excluded goods. (Henry Daubney Brideware, 28, Hamilton Square, Birkenhead, December 19, 1894. Device: A hand touching a device and the words "Device instantly touches the spot." The essential particular are the words "Homocooce" and the device.

No. 184,995.—Instruments, Apparatus, and Con
tivances, not medicated, for surgical or curative purposes, or in relation to the health of men or animals.

—Southall Brothers and Barclay, 17, Bull Street, Bir
ingham. January 16, 1895. Device: Three links of a chain, with a motto (Southall Brothers). The essential particular is the combination of devices.

No. 185,593.—Olive Oil.—Southall Brothers and

Barclay, 17, Bull Street, Birmingham. February 14, 1895. Device: A shield with device of a female figure carrying a pithoer, and a motto (Dulce qua purum). The essential particular is the device.

New Remedies.

[The notes given under this heading for the information of dispensers, embody recent suggestions in therapeutics, and cover both new drugs and preparations, and old ones under new aspects. The word "parts" is used to represent parts by weight, both for solids and liquids.]

CALCIUM BROMIDE AS A SEDATIVE IN TYPHOID.—Dr. G. Sée proposes the use of bromide of calcium as a sedative, administering a dessertspoonful of 10 per cent. solution diluted with twice its volume of water (Revue de Thérapeut., Jan. 1, 1895).

DRESSING FOR TEMPORARY TREATMENT OF SEVERE WOUNDS.—Brèna recommends as a dressing for embalming crushed limbs or other severe wounds, so that surgical intervention may be safely postponed, an antiseptic gauze compress saturated with the following unction dressing:—Salol, resorcin, and antipyrine, of each 12 parts; boric acid, 20 parts; iodiform, 1 part; vaselin, 180 parts (Revue de Thérapeut., Jan. 1, 1895).

THYMIUM GLAND SECRETION AS A HEMOSTATIC.—Wright finds that the following preparation of thymus gland of the calf is powerfully hemostatic. One calf’s sweetbread is cut into small pieces, and macerated for two or three hours; then it is left for thirty-six hours, with frequent shaking in the following menstruum.—Sodium carbonate 3 to 6 parts; chloroform, 15 parts; distilled water, 300 parts; filter, and add chlorinated lime, 30 parts. Again filter, and add finally sufficient caustic soda to produce a faintly alkaline reaction. Preserve in well-stoppered bottles. Wounds are simply touched with the liquid (Revue de Thérapeut., after Chem. Centr.).

ANTIPYRINE AMYODALATE IN WHOOPING COUGH.—This body, which has been named “tussol,” is obtained as a crystalline compound by treating antipyrine with amygdaloid acid. Dr. Rehn has used it in over sixty cases of whooping cough; the mean duration of the attack in cases treated by tussol is three weeks for those of ordinary severity. Under one year the daily dose is from 15 to 30 centigrammes in separate quantities of 5 or 10 centigrammes; from two to three years, from 20 to 40 centigrammes to 1 gramme daily; from five to seven years, 15 gramme daily. Older children may take from 3 to 6 gramme daily, given in a day in doses of ½ gramme at a time. It may be given in the following form to young children:—Tussol, 23 gm.; water, 80 gm.; syrup of orange, 20 gm. Each teaspoonful contains 10 centigrammes of tussol. It should not be given in milk nor soon after a meal, composed of that food (Münchener Med. Wochenschr.).

GUAIACOL APPLIED EXTERNALLY IN PLEURISY.—Miron-Ligiae uses the following in pleural effusions to the whole posterior portion of the thorax, two applications being made at an interval of twenty-four hours. Guaiacol, 3 parts; glycerin, 20 parts; tincture of iodine (Codex), 20 parts (Rev. de Thérap., Jan. 1, 1895).

PILOCARPINE HYDROCHLORIDE IN PREVIGO.—Esche-rich injects twice daily from 1 milligramme to 2 centigrammes of the salt.

LOSOPHAN IN PAVUS.—After cutting off the hairs from the diseased parts and thorough washing with soft soap and water the following ointment is applied twice daily:—Losophan, 4 parts; cold cream, 9 parts; lanoline, 24 parts (Med. Presse.).

STRONTIUM LACTATE IN ALBUMINURIA.—Ried confirms the value of strontium salts as diuretics in anaarca and also in mitral contraction, while in albuminuria the amount of albumin excreted is sensibly diminished. Since salts of strontium given in powder frequently cause nausea and thirst, it is preferable to give the lactate in solution, thus:—Lactate of strontium, 25 parts; water, 150 parts. Three or four tablespoonfuls in the day. (Wiener Med. Wochenschr.).

NITROGLYCERIN IN SCATICA.—The following mixture is recommended in doses of 1 to 3 drops three times a day:—

Solution of nitroglycerin (1 per cent)... 2 parts.
Tincture of capsicum.................................. 6 "
Peppermint water ...................................... 12 "
(Revue de Thérap.)

EXTRACT OF VIBURNUM IN PAINFUL DYSMENORRHEA.—In severe cases, absolute rest in bed should be ordered, with the following mixture:—Potassa bromide, 10 parts; and, is then gradually, 10 parts; liquid extract Viburnum, 20 parts; brandy, 30 parts; syrup of orange, 30 parts; distilled water, 120 parts. From two to four tablespoonfuls to be taken during the day (Therap. Monats.).

ASAFETIDA IN ABORTION AND GYNECOLOGY.—Dr. Warman strongly advocates the use of asafoetida during pregnancy to prevent abortion and modify the difficulty of chronic constipation, which is often a serious factor to treat in such cases. He administers the asafoetida in pills, each containing 10 centigrammes of the gum resin (about 15 grain). Two pills are taken daily, gradually increased up to ten pills per day, with a subsequent diminution of the dose until the birth takes place (Therap. Monats., Jan., 1896).

CARBOHYDRIC INJECTIONS IN HEMOPHILIA.—Papp and others advocate the direct injection of 5 to 10 drops of equal parts of glycerin and phenol into the nodules by means of a Pravats syringe. The needle should be allowed to remain in the puncture for a few minutes after injection. Before practising the injection the rectum should be cleansed and disinfected. In the second week after the injection the nodules soften, and entirely disappear in a few weeks (Therap. Monats., Feb., 1895, after Pester Med. Chirur. Presse).

LYSOL IN INFECTIOUS FEVERS.—Tison gives a tablespoonful every two hours of the following mixture in cases of infectious fevers:—Lysol, 6 to 12 minims; oil of peppermint, 1 to 2 minims; simple syrup, 30 grammes; infusion of lime-tree flowers, 90 grammes (Revue de Thérapeut.).

POTASSIUM CANTHARIDINUM IN PHLEBITIS.—The following is the preparation for the solution of potassium cantharidinum employed in the treatment of phlebitis first suggested by Liebrech and employed by Petteruti. Twenty centigrammes of pure cantharidin, and 40 centigrammes of dry potash, free from carbonic acid are added to 20 C.C. of water heated in a water bath until dissolved; the solution, if heated, is then gradually diluted to 1000 C.C.; it is then cooled to 15° C., and the necessary amount of sterilized water added to make it up to 1 litre. Each gramme of this solution contains 0·0002 gm. of pure cantharidin. The treatment commences with an injection of half a Pravats syringeful, i.e., half a cubic centimetre or 0·0001 Gm. of cantharidin (Therap. Monats., Feb., 1896).
Notes and Queries. 

[The information given in this column includes notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient general interest.]

ECZEMA CAUSED BY A HAIR-DYE. [840]. Dr. Du Castel reports a case of eczema of the scalp following the use of a hair-dye. This was composed of two liquids—one (colourless) was simply peroxide of hydrogen (white, or dark-coloured) contained a large quantity of potash and of pyrogallic. These irritant substances, in the doctor's opinion, perfectly account for the morbid state of the skin (L'Union Pharm., April, 1898).

PREPARATION OF SANTONIN BISCUITS. [841]. M. G. Apostolidès recommends the following rapid method for temporarily preparing santonin biscuits. Dissolve 1 gramme of santonin in a mixture of 2 grammes of chloroform, and 1 gramme of alcohol. Take twenty biscuits and drop upon each 10 drops of the solution and allow to dry. Each biscuit will contain 0.06 gramme (nearly 1 grain) of santonin (Journ. de Pharm. et Chim., April 15, 1898).

PIXOL. [842]. This is pine-wood tar treated with soft soap and caustic potash. Doualessy finds an aqueous solution containing 10 to 13 per cent. applied three or four times daily, excellent in dermatitis from various causes, in pruritis, soft chancres, and other venereal sores (Annal. Dermat.).

MEDICATED CRAYONS FOR SKIN DISEASES. [843]. M. J. Monties modifies Unna's formula for the basis of these articles thus—Cocoa butter, 75 parts; hard paraffin, 5 parts; olive oil, 10 parts; active ingredient as directed, melt the paraffin with a part of the cocoa butter, add the rest, and melt with a gentle heat. Triturate the active ingredient in a warm mortar with the oil, then pour in the melted fat, and mix. Cool the mass in glass tubes, oiled on the inner surface, and open at both ends; one end is closed with a cork to serve as a mould. These pencils are firm, but melt at the temperature of the body; they keep well, and are convenient to handle. The melted portion does not extend beyond the part touched (Journal des Mal. Cutan., Feb., 1895).

LAVENDER OIL FOR STERILISING SURGICAL CATHETERS. [844]. Dr. Schüller recommends the use of pure lavender oil for the sterilising of surgical catheters. When the strings are digested in a steriliser at a temperature from 106 to 110° C. for half an hour, in wide glass tubes filled with the oil and fitted with glass stoppers. Lavender oil has the advantage over other fluids that it does not weaken the catgut, which retains its resistant properties after several sterilisations. The thorough sterilisation of catgut by means of lavender oil has been proved both by bacteriological tests and by practical experience (Spital. Monats., Feb., 1895, after Arztl. Prakt.).

ASAFROL AS A REAGENT FOR ALBUMIN, ETC. [845]. Dr. Rieger states that a 10 per cent. aqueous solution of asafrol is a good reagent for albumen, albumoses, peepin, and peptone. About 4 C.C. of the liquid to be tested is rendered acid with 2 drops of concentrated sulphuric acid, then treated with 10 drops of the asafrol solution; in the presence of any of the albumoses, a precipitate occurs. The precipitate due to albumoses is better on heating, while that from albumoses or peptones dissolves on warming and reappears on cooling. If albumin and peptone are present in the same liquid the albumin may be removed by filtering the hot solution; then when the peptones or albumoses may be detected in the cold filtrate (Therap. Monats., Feb., 1896, after Wiener Klin. Wochenschrift).

NOTICES, LETTERS, AND ANSWERS TO CORRESPONDENTS.

++ Communications should reach the Editorial Department, 17, Buckingham Square, W.C., not later than the first post on Wednesday, if publication be desired in the next issue of the Journal; though prompt publication cannot always be guaranteed.

Matter intended for publication must be written in ink, on one side of the paper only, and be authenticated by the name and address of the writer, as necessary for publication, but as a guarantee of good faith.

No notice can be taken of anonymous communications, and contributors are requested, as far as possible, to append their proper signatures rather than pseudonyms, a greater value being thus given to any opinions expressed.

When illustrations are necessary, pen and ink drawings, consisting entirely of clean and sharp lines—and, preferably, twice the required size—must be supplied not later than a week before the proposed date of publication.

MINIMUM CUTTING PRICES.—Messrs. Blondeau and Co., of Ryland Road, N.W. write as follows:—Our attention has been called specially to the letter of Mr. Charles P. Allen, page 809th, ult. on minimum “cutting” prices, and we think it due to ourselves that we should explain that we are of the opinion that the full retail prices of proprietary articles are those which should be advertised to the public by the manufacturers. Though we advertise a large number of preparations, and our advertisements appear in some thousands of papers, we have had hardly any complaints of the prices being wrong. Our instructions to our advertisers to state the retail prices are respectfully communicated to the manufacturers. If the retailers will kindly take into consideration the good profits on “Vinoila” soap and preparations that we have secured to them during the last few years, we hope they will not find very much fault with our policy, indeed, the fact that so slight a slip in the case of only one of our cheapest preparations causes so severe a comment is to our mind one of the strongest evidences that could be adduced to prove the success of our fair-profit system. The correctness of our policy has been a fair profit to the retailer, and this we are sure has been very much appreciated.

CORRECTIONS.

Plymouth.—Mr. James Cocks writes to say that in the report of the quarterly meeting of the Plymouth, Devonport, Stonehouse, and District Chemists' Association contained in the Journal for April 30, p. 417, the name was incorrect, to be regarded as having said the public should be more "considered" on Sundays, instead of which, it should have been "considerate." Reference to the written copy shows that the composer was quite justified in interpreting the word as it appeared.

Glasgow.—Mr. Alex. Laing draws attention to several errors in the report of the Glasgow Association on the Revision of the British Pharmacopoeia, as published in last week's Journal. It is stated that official reports from associations are not written with sufficient clearness and accuracy to prevent the frequent recurrence of such unfortunate mistakes. In the following instance the error exists in the manuscript supplied to us:—Page 293, under "proposed omissions" for "acid. lacticum" read "acid. lacticum dilutum"; p. 294, in the formula for mixture guaisac read "cinnamon water to 31/2," and in the formula for a mode of potassio zincacetat read "glycerin, 50 minima." Two compositors' errors also occur in the first column on page 294, where the dose of acid lacticum should have been stated as "up to 20 minima," and the proportion of powdered sugar in the formula for pulv. cerasumumus as "2 parts."
"THE MONTH."

Calcium Phosphate in Milk.

L. Vaudin has studied the conditions under which calcium phosphate exists in milk, and finds that the latter contains an alkaline citrate which helps to retain the calcium salt in solution. The solution is due, however, to the part played by lactose in the presence of the alkaline citrate. Every influence which tends to modify or destroy the molecular equilibrium of the salts dissolved in the milk, tends at the same time to precipitate calcium tri-phosphate with excess of the base in the form of citrate (Comp. rend., cxx., 785).

Milk Analysis.

According to H. Leecour, the examination of the serum of milk after coagulation is capable of furnishing useful data in milk analysis. The whey is obtained by treatment with a trace of dry rennet. The coagulated milk is thrown on a filter and the bright serum collected. Normal milk serum has a density of 1.029 to 1.031 at 15° C., and the weight of the dry extract obtained by evaporation ranges from 6.7 to 7.1 per cent. A milk which gives figures below these limits is regarded by the author as watered. He fixes the following for the calculation of the amount of added water:

<table>
<thead>
<tr>
<th>Extraitive per</th>
<th>100 c.c. of serum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Density at 15° C.</td>
<td></td>
</tr>
<tr>
<td>Pure milk</td>
<td>1.030</td>
</tr>
<tr>
<td>100 parts milk + 10 parts water</td>
<td>1.0275</td>
</tr>
<tr>
<td>&quot; &quot; &quot;</td>
<td>1.025</td>
</tr>
<tr>
<td>&quot; &quot;</td>
<td>1.023</td>
</tr>
</tbody>
</table>

This method should prove useful in the examination of samples of milk which have clotted from prolonged keeping previous to analysis (Journ. de Pharm., [6], i., 395).

Permanganate as an Antidote to Opium.

Dr. James Carpenter, of Pottsville, Pa., who has previously testified to the extreme value of the administration of permanganate in cases of opium poisoning, now records another case in which recovery of an apparently moribund patient was brought about by this antidote. The case was that of an infant in a state of profound opium narcosis, due to an overdose of "sodium" syrup. After failing to produce any alleviation of the symptoms by four hours' active treatment, as a last resource 5 minims of saturated solution of permanganate of potassium was injected into the thigh. In an incredibly short time all the alarming symptoms subsided, respiration improved, and consciousness quickly returned (Therap. Gazette, March 15, 1886).

Freezing-point of Solutions.

Nernst and Aebli show that the discrepancies in the published results of different investigators who have determined the freezing-points of dilute solutions, are probably due to the fact that the observed freezing-points must in general be different from the true freezing-points, or the temperatures at which solid and liquid are in equilibrium, and that the observed freezing-points should be regarded as functions of the size of the apparatus used, the temperature of the cooling-bath, the rate of stirring, etc., etc. A partly frozen liquid, uninfluenced by the temperature of its surroundings, will tend to reach the true freezing-point at a rate proportional to the difference between its actual temperature and that point, whilst...
in practice, such factors as the limited amount of substance employed and the effect of the temperature of the surroundings will cause unfrozen liquid to strive to attain a definite "convergence temperature." The observed freezing-point, then, will only be the true freezing-point if the "convergence temperature" is equal to the latter, or if the rate at which the temperature of the partly frozen liquid approaches the freezing-point is infinitely great as compared with the rate at which that of the unfrozen liquid approaches the "convergence temperature." Failing the fulfilment of one of these conditions, experimentally determined corrections must be applied. In the case of dilute alcohol and common salt such corrections were found to be inapplicable, but with sugar, by varying the experimental conditions, a 1 p.c. solution gave molecular depressions of the freezing-point, varying between 1° and 2.1°—limits even further removed than the most extreme ones given by the results of previous observers (Arrhenius, 2°2; Racoult, 2°7; Pickering, 2°61; Jones, 2°18; Loomis, 1°91). On correction of the observed depressions, however, they all gave practically the theoretical value (Zeits. f. phys. Chem., and Nature, li., 617).

Formalin and Food-Stuffs.

Weigle and Merkel have investigated the action of formalin, with the view of ascertaining if it could be used as a food preservative. They find that in the case of milk its use is followed by marked changes in the behaviour of the casein, which, though obscure in their origin, are such as to warrant the prohibition of its use for preserving this food-substance. They also consider that exact investigations should be undertaken, with the object of ascertaining the least means of detecting the addition of formaldehyde, as in the case of boiled milk they were not able to detect it with certainty (Forschungs- Ber., ii., 91).

Determination of Alkaloids.

Dieterich has compared the three following methods for the determination of alkaloid in narcotic extracts and powerful drugs, viz., the Schweisager-Sarnow method by shaking out, Van Ledden-Hulshebosch by the performation method, and the Helfenberg ether-line method. His results show a perceptible and regular low percentage by the Van Ledden-Hulshebosch, whilst the ether-line method shows usually slightly higher figures than the Schweisager-Sarnow method. The latter he considers sufficiently accurate for practical purposes and very easy to perform. For general accuracy he recommends the ether-line process, to which, however, there are some exceptions, as for instance, for ipecacuanha, for which he considers it unsuited. For titration, porcelain basins should be used in the place of glass beakers, using from 1 to 3 drops of solution of hematoxylin as indicator. For ipecacuanha, Keller's method yields good results (Oester. Pharm. Zeitschr., xli., 242).

The First Mercurial Thermometer.

M. Maze points out that sixty-two years before Fahrenheit made such an instrument, a mercurial thermometer was used by Ismael Boullian (1659). It had an arbitrary scale, the value of a degree being about 10°7 C., and the zero of the scale at -53°76 C. The temperature of melting ice would be 5°34, and that of boiling water 15°27 (Comp. rend., cxx., 732).

Assimilable Nitrogen.

M. Pagnoul concludes as the result of an extended investigation that heavy rains may carry off from rich lands a considerable amount of nitric nitrogen, but that plants growing on the soil may prevent this loss. Carbon disulphide is found to check the action of the nitric ferment temporarily, besides causing a temporary suspension in the chemical action during the transition stage in which organic nitrogen passes through the ammoniacal form into the nitric form. The nitrous form is also supposed to be an unstable transition stage (Comp. rend., cxx., 812).

Separation of Synthetic Remedies.

Dрагородек's shaking-out method. From an acid solution he found petroleum spirit removed guaiacolbenzol, guaiacol salicylate, benzenesulphol, alcoh, agathin, salacetol, methylsulol, orthocresol, para cresol, metacresol, benzosulcol, malakin, and thermolin, but traces only of guaiacol cinnaamate and naphthol carbonate. Benzol removed salophen, pyrodo, guaiacol cinnaamate, lae参观 8-naphthol benzoate, galanol, alcoh, naphol Na, Li, and Sr; after previous boiling with hydrochloric acid—neuradin, malakin, thermolin, and traces of galanol. Chloroform dissolved pyrodo and alanol. From ammoniacal solution petroleum spirit removed phenocoll; benzol, tolpyprine; chloroform, alanol; amyl alcohol, galanol (Pharm. Post, xxviii., 160).

Vasogen.

G. Kottmeyer has examined Dahmen's vasogen, and finds that when heated on a water bath it loses ammonia gas, and its power of emulsifying with water is simultaneously destroyed, but the latter is restored by passing ammonia gas into the oil after heating. Oleic acid was also found to be present to the extent of about 20 per cent, and a mixture of vaselin oil with 25 per cent of crude oleic acid and 5 per cent of alcohol, yielded, when saturated with ammonia gas, the counterpart of vasogen. Vasogen spiss appeared to be a similar mixture of oleic acid with solid vaselin or petroleum jelly, saturated with ammonia. Creosote vasogen can therefore be prepared at about one-fifth of the price of the factory-made preparation, as follows:—Pure creosote, 20; white vaselin oil, 60; common oleic acid, 20-25; ammonia gas, g.4. (Pharm. Post, xxviii., 68).

Powdered ipecacuanha.

According to the French Codex, in powdering ipecacuanha it is essential to reject the last fourth of the drug, and F. Ranwez and O. Campion, considering that this fact and the cost of the entire root were incompatible with the price charged for the powder, have examined sixty-two commercial specimens. Nineteen were found to be adulterated with false cultivated ipecacuanha or entirely substituted by the latter; twenty-four contained an undue proportion of woody fibres, which should have been rejected with the fourth part of the drug that most resists pulverisation; six contained various impurities, one appearing to consist partly of Carthagea ipecacuanha; four others seemed also to be mixed with Carthagea root, which, however, is difficult to differentiate; and nine only presented exclusively normal characters (Annales de Pharm., i., 114).
Writing to the *Therapeutic Gazette*, Dr. Brindisi states that of all the proposed substitutes for iodine form, he has found none equal to bismuth salicylate, and in certain cases he regards it as even superior to that body, since not only is it odourless, but it does not cause any irritation to the epidermis.

**Action of Gelatin on Solutions.**

Mills and Sawers find that the introduction of gelatin into saline solutions results in the combination of the salts with the gelatin. Chrome alum (potassic) appeared to be taken up unaltered, the resulting compound being quite insoluble in boiling water, but it was slowly dissolved at a gentle heat by an equal weight of acetic acid diluted with about twice its weight of water, the solution leaving an insoluble residue when it dried up. alumina alum (potassic) was absorbed by gelatin to form a compound, which dissolved slowly in boiling water; nickelous sulphate gave a partly soluble gelatin; cobaltous sulphate a completely soluble one; and cupric sulphate a partly soluble compound (*Journ. Soc. Chem. Ind.*, xiv., 292).

G. Kottmeyer has examined Dr. Dahmen's hemalbmin, a preparation that has been claimed not only as a remedy for chlorosis, tuberculosis, and many other diseases, but as a means of prolonging life, and superior in nutritive power to meat. It contains, according to Kottmeyer, 0.26 per cent. of iron, and is neither more nor less than incompletely digested blood. An apparently identical preparation can be made by mixing 50 c.c. of hydrochloric acid and 50 c.c. water with 1000 grammes of defibrinated blood, which then becomes soluble in boiling water. On standing a jelly is produced, which can be broken up by hand and dried (*Pharm. Post*, xxvii., 101).

**Casein in Ointments.**

Casein is employed as an ointment basis by Professor Unna. It is freed from fat by washing with alcohol and ether, then emulsified by the addition of potash or soda (3 parts to 97 of casein), so as to obtain a neutral product. A preparation consisting of casein, 2 parts, and glycerin, 1 part, mixed readily with soft paraffin, 3 parts, the product resembling thick condensed milk. Acids, calcium salts, and other substances which precipitate casein are of course incompatible with it. Tar and balsams should be mixed with one-fourth their weight of green soft soap before incorporating with the casein, and other substances previously brought into a semi-fluid condition by the addition of soft paraffin and water. Such ointments are said to come more intimately in contact with the skin (*Scalpel and Journ. de Pharm. d'Anvers.*, li., 134).

Several species of *Gastrolobium*, a genus of leguminous plants, prove very fatal to live stock in Western Australia. Animals eat the foliage especially the flowers, and the finest and strongest animals are the most easily poisoned, death taking place in about five hours, apparently by paralysis of the action of the heart and lungs. Although the noxious properties of these plants have been known for fifty years or more, no attempt appears to have been made to ascertain the exact physiological action with a view to provide an antidote. An interesting account is given by Drummond in Hooker's *Journal of Botany,* [1], vol. iv., p. 82-3; [2], vol. i., p. 93-100, concerning these plants, and in the *Pharm. Journ.* [1], vol. vi., p. 311. Some experiments made on animals with the destruction of one of these plants by Dr. Algeron Frongron (i.e., pp. 312-315), are also on record, but the investigation does not appear to have proceeded further. Now that Western Australia is being opened up more extensively, perhaps these plants may receive more attention. Specimens of *G. grandiflorum* have recently been presented to the Museum of the Pharmaceutical Society, and there is at disposal a sufficient quantity for a preliminary investigation by any chemist or physiologist who may take an interest in the matter.

Veratrum Viride. Green hellebore and its minute structure are discussed in the *American Journal of Pharmacy*, for April, by Professor E. J. Bastin, who states that he has observed in one instance the fraudulent substitution of the rhizome and rootlets of *Symplocarpus foetidus* for those of *Veratrum viride*. They are larger generally than the latter, have a thicker cortex and smaller starch grains, as well as a characteristic fetid odour.

Free Iodine. A short time ago, Dr. D. Robertson, the esteemed naturalist of Melbourne, exhibited at a meeting of the Glasgow Natural History Society a specimen of *Bonnemaisonia asparagoideae*, which had stained the paper blue on which it was mounted. The specimen examined microscopically by Mr. Battles showed that the paper had starch grains on its surface, and that the coloration was due to iodine colouring these grains. This is explained by the discovery of Dr. Golenkin (*Bull. Soc. Imp. Nat. Moscou*, 1894, pp. 267-268), that *Bonnemaisonia* in drying excretes free iodine. The iodine appears to be contained in the vacuoles of special cells. Herr K. Bruna has pointed out another curious feature in this species. Every branch contains a large number of strongly refringent bodies which are an intense blue in reflected light. These bodies are contained in the enveloping gelatinous layer, but not in the cells (*Ber. Deutsch Bot. Gesell.*, xi., 178 through *Journ. Roy. Mic. Soc.*, April).

**Histology of Elder Root.** Moeller draws attention to the histological characters of elder root. This root appears to be poisonous in its fresh state, but not in the dry state. The distinctive characters of the powdered root are the wide bast fibres, the brown contents of the laticiferous tubes, which appear in the form of spheres, or drops, or in masses, and the fragments of wood with the cells of the medullary rays attached to them. These particulars permit of the powdered root being distinguished from belladonna; if the powder of the latter be prepared from the starchy autumnal root the size and character of the starch grains may also be utilised for the purpose of diagnosis (*Pharm. Post*, xxvii., 113). A. Chauveau and C. Phisalix have made an interesting contribution to the study of variability and power of transformation in microbiology, by the discovery of a new variety of anthrax bacillus (*Bacillus anthracis claviformis*). They believe this is derived from virulent *B. anthracis*, though it possesses little or no toxic action, and they have not as yet been able to bring back the new variety to the original form.
It is obtained by inoculating the lymphatic ganglion of a guinea-pig with attenuated anthrax bacilli, and is found to retain in a very slight degree the immunising power of the attenuated culture of the original form (Comp. rend., cxx., 601.)

Oil of Bay. Power and Kleber have examined this oil and separated from it eugenol, myrcene—a hitherto unknown terpene, chavicol, methyl-eugenol, methyl-chavicol, phellandren, and citral, the names of the constituents being arranged according to the relative amounts in which they occur. The specific gravity of the oil varies from 0.875 to 0.886 at 15°C., and is commonly about 0.970, and the amount of phenols present ranges between 60 and 65 per cent., being approximately in direct proportion to the specific gravity. The freshly distilled oil forms a perfectly clear solution with alcohol. It is suggested that the fact that the oil contains no pinene in connection with the specific gravity, may be utilised for the detection of adulterations with oil of turpentine or other oils containing pinene. If 10 C.C. of a suspected oil be taken and 1 C.C. slowly distilled off in a small fractionating flask, the pinene will constitute most of the mixture of that present that may be present. On adding to this liquid, a test-tube, first 1 C.C. of amyl nitrite, then 2 C.C. of glacial acetic acid, and subsequently, whilst the tube is immersed in a mixture of ice and salt and constantly agitated, a mixture of equal parts of glacial acetic and concentrated hydrochloric acids (drop by drop so long as the liquid has a bluish coloration), the presence of pinene will be indicated by a white crystalline precipitate of pinenes nitrosochloride, C₉H₈O₂NCl. Ten per cent. of oil of turpentine in oil of bay may thus be detected.

(Pharm. Rundsch., xili., 60.)

A. Neve, surgeon to the Kashmir Mission Hospital, India, strongly recommends the use of sawdust pads as a staple surgical dressing material. The sawdust is packed in muslin bags, and the pads are readily rendered either aseptic or antiseptic. In practice they are impregnated the day before use with a 1 in 2000 solution of mercuric zine cyanide, or sterilised in a Cathcart’s or Schimmelbusch’s oven (Lancet, 3759, 659.)

Dye: R. T. Williamson has had prepared a bread substitute for diabetic patients, consisting of cakes prepared from aleuronaot and coco-nut powder.

Aleuronat is a yellowish powder containing 80 to 90 per cent. of vegetable albumin and only 7 per cent. of carbohydrates. To make it into cakes 2 ounces of deacicated coco-nut powder is mixed with a little water containing a small quantity of German yeast, into a paste which is kept for half an hour in a warm place. The sugar in the coco-nut is decomposed by fermentation, and the paste becomes spongy. Two ounces of aleuronat, one egg beaten up, and a little water sweetened with saccharin are now added, and the whole is well mixed into dough, which is then divided into cakes and baked in a moderate oven for twenty or thirty minutes. If deacicated coco-nut powder be obtained free from sugar, it is then only necessary to mix the whole of the ingredients at once without the intervention of yeast. The cakes are most palatable when newly made, and are improved by being buttered (Brir. Med. Journ., 1791, 929.)

THE SOCIETY OF DRUGGIST-APOTHECARIES IN EDINBURGH.

ARTICLES OF ASSOCIATION, A.D., 1785.

We, the persons subscribing, all druggists or apothecaries in Edinburgh, convinced that persons of our profession would derive many advantages from being associated together and having a mutual fund, have therefore voluntarily associated, and do hereby associate, unite, and constitute ourselves into a Society or body collective, under the title and denomination of the Society of Druggist-Apothecaries in Edinburgh, and in order to the establishment of the said Society and to its future regular management, we, the original constituent members, as well as those persons who may afterwards accede to or sign these presents of subsequent dates, do not only unanimously agree to and approve of the following resolutions, but bind and oblige ourselves (each for himself) to obey and conform to the same so long as they shall continue in force and unaltered by the Society in the manner to be hereinafter explained.

And, in the first place, with regard to the members of which the Society shall consist, it is agreed, primo, That no person shall be admitted into this Society but Druggists or Apothecaries by profession; secundo, That it shall be in the power of the Society, by regulations or bye-laws to be passed in the manner to be hereinafter explained, to require that intrants shall serve a regular apprenticeship, undergo examinations, or have such other qualifications as the Society at the time shall think proper; tertio, Every Druggist within Edinburgh or the liberties thereof, or in Leith, having the qualifications required by the Society for the time, may apply for admission, and at the next meeting subsequent to his application it shall be taken into consideration, and if there shall appear a majority or plurality of the members of the Society present at the meeting and qualified to vote in favour of the application, "a shall be admitted a member upon his acceding to these presents, or granting and subscribing an obligation to comply with and obey the regulations of the Society then in force; quarto, if any member of the Society, after admission, shall refuse to obey the laws and regulations thereof, or shall be guilty of any delinquency, the Society shall be at liberty to fine, censure, or expel him. The power of inflicting a fine or censure shall be in the majority of the qualified members of the Society present at any meeting, and may be exercised in any form. Expulsion shall never take place unless when a regular accusation and complaint is made in writing at one meeting and found relevant to infer expulsion, and the member accused found guilty by the votes of two-thirds of the qualified members present at another meeting where there shall not be fewer members present than two-thirds parts of the whole Society.

In the second place, with regard to the meetings of the Society, it is agreed, primo, That there shall be held annually four general stated meetings, viz., on the first Monday of January, the first Monday of April, the first Monday of July, and the first Monday of October, commencing from the first Monday
of October seventeen hundred and eighty-five, and continuing thenceforth on the days aforesaid in time to come, at such hours and at such convenient places as the Society may from time to time appoint; secundo, Besides the above four quarterly stated meetings it shall be in the power of the President at the time, with the advice of a quorum of the Committee or Council aforesaid, to call an extraordinary general meeting upon the occurrence of any business of importance which could not be delayed till a stated meeting; tertio, The whole members of the Society in Edinburgh at the time or within three miles thereof, and capable of attending business, shall punctually attend in person all and every one of the said stated or extraordinary meetings, under the penalty of two shillings and sixpence, to be forfeited and paid by each absent member to the Society toties quoties, the penalties to be levied at the meeting immediately posterior to their being incurred; quarto, That the members of the Society may have no excuse for non-attendance, the Society shall choose an officer, who shall be obliged to summon each member to attend, at least forty-eight hours before each meeting of the Society, stated or extraordinary, by giving or leaving for him a written or printed summons; quinto, No fewer than a majority or plurality of the Society for the time residing in Edinburgh, its liberties or Leith, and qualified to vote shall be deemed a quorum sufficient to constitute a general meeting.

In the third place, with regard to the office bearers of the Society, it is agreed, primo, That the office bearers shall consist of a President, a Vice-President, a Committee or Council of five members (of whom the President and Vice-President shall always be two, and of whom any three shall be a quorum), a Treasurer, and a Secretary or Clerk; secundo, These office bearers shall all, except the Secretary, be elected and chosen out of the members of the Society, by a majority of the votes of the qualified members present at the meetings held for their elections; tertio, the said whole office bearers shall be elected annually, the first election shall take place upon the first general meeting of the Society held after signing these presents, and the next at the general meeting held a full twelvemonth thereafter, and so on annually upon the same day in time to come; quarto, members when elected into their offices shall be obliged to accept of them under the penalty of one guinea, with these exceptions, that no member shall be obliged to accept for two years immediately succeeding each other nor for above two years out of every five years, and as the Treasurer is hereby required to find caution for his faithful management of the funds of the Society that no member shall be obliged to act as treasurer, unless two members with whom the Society shall be satisfied shall immediately upon his election declare themselves ready to join with him as cautioners to that purpose; quinto, Having accepted of their offices the members elected shall be obliged to execute and perform the duties thereof faithfully, under the penalty of ten shillings and sixpence sterling for each failure toties quoties; sexto, In the event of any of the aforesaid offices becoming vacant the same shall, as soon as possible, be filled up by new elections, and in the meantime or in the absence of any of the office bearers, the Society may by a majority of votes choose one of their number to officiate, pro tempore, in his place; septimo, The duties and business of those different officers, so far as not fixed or ascertained by these presents, may be settled and pointed out by the bye-laws of the Society, to be made and passed in manner hereafter explained.

In the fourth place with regard to the funds of the Society, it is agreed, primo, That the original constituent members shall be obliged immediately after signing these presents to pay to the Treasurer, to be elected by the Society, one guinea each towards raising a fund for the purposes of the Society, and every person to be admitted afterwards shall be obliged to pay to the Treasurer the sum of two guineas, or such other sum as shall be afterwards fixed, as entry money by the Society; secundo, The whole original members, as well as those who may be afterwards admitted, shall annually contribute and pay to the Treasurer for the time one pound sterling, and that by four equal portions or moieties, one whereof to be payable at each of the forenamed stated meetings of the Society before mentioned, during the lives of the members and their continuing members of the Society, beginning the payment of the first moiety at the first meeting after the entry of each member, with a fifth part more of penalty in case of failure and interest from the time it is due until payment, provided always that it shall be in the power of two-thirds of the Society present at any general meeting to exempt from payment of said annual contribution any member who shall appear unable to pay the same through a misfortune or loss of business, but that only during the continuance of such inability; quarto, And for ensuring the more regular payment of all sums whatever due to the Society by members, whether entry money, contribution, money fines, or other sums, it is provided that no member that is in arrear or owing the Society any sum whatever shall be qualified to propose or make any motion, or to vote on any question whatever, nor be capable of being elected or holding any office therein, or of claiming or reaping any part of the benefits thereof, until the whole sums so owing shall be fully paid up, with this provision only that if a member or officer shall fall in arrear he shall hold his office till a new election take place, which it is hereby declared shall not be delayed beyond general meetings after the member in office has fallen into arrear; quintio, It shall also be competent to the Society if the members in arrear continue so for the space of two years to expel them altogether, by which they shall forfeit all right in the Society, or its funds and the same shall accrue to the remaining members; sexto, The whole sums of money to be thus collected with the forfeitures and penalties and every other sum which may come into the hands of the Society or their Treasurer shall belong to the Society as a body, and be at their own absolute disposal, and shall be applied to the purposes of the Society; septimo, When the Treasurer shall have more
of the Society's money in his hands than will be necessary for answering immediate contingencies, he shall lend out the same at the sight of the aforesaid Committee or Council to such banks or banking houses as the Society may direct: and take notes for the same or bills payable to himself for behoof of the Society, and bearing such interest as can be procured; octavo. But if the funds of the Society shall ever increase so that the Society shall think proper to accumulate into a capital sum or sums, then such capital sums shall be lent out in name of the Society and the securities therefor taken in favour of the President, Vice-president, Treasurer, and Committee or Council before mentioned for the time being, remanatim, or to any three of them (who shall be a quorum; the Treasurer while in office being always one and sine quâ non), and to their assignees as trustees for behoof of members of the Society, to whom the said trustees shall always be liable and accountable pro rata for the whole acts and deeds in relation to these premises; nono, The rights to all property to be acquired or purchased by the Society shall be taken and conceived in the same terms; decimo, no part of the Society's moneys shall be lent at any time to any member or members thereof, nor shall members be received as cautioned with others thereof; undecimo. None of the sums belonging to the Society excepting salaries or usual contingencies shall be paid away or lent out without a special resolution of the Society for that purpose.

In the fifth place, with regard to the objects and purposes of the Society and their mode of carrying on business in time coming, it is agreed, primo, That the object and purpose of this Society is the regulation of their trade concerns, and the uniformity of the retail prices, but not of the wholesale prices, which are hereby declared to be excluded, and also the management and disposal of their funds; secundo, As from the nature of this business it must be continually varying, so no further regulations can at present be made about it, but it shall be in the power of all and each of the members, from time to time, to prepare such new regulations, laws, resolutions, or motions as he may think for the benefit of the Society; terto, Such proposals shall always be made in writing and presented to the Society at the meeting before they shall be decided upon; quarto, If these proposals, motions, or questions shall be made with a view to repeal or alter any of the fundamental rules of the Society as laid down in these presents, they shall be rejected, unless there appear in their favour three-fourths of the whole members of the Society; but if they are for carrying into execution the purposes of the Society in a consistency with these presents, if there shall appear a majority of the members present and qualified to vote at the meeting, when they are discussed, in their favour, they shall be passed into a bye-law and become binding on all the Society: quinto, In the course of discussing all business the President shall have power to regulate the debates, and to impose fines for irregularities; sexto, When the votes of the members present shall be equally divided, the President's vote shall be taken and shall be decisive; and lastly, WE, the Whole members of this Society, hereto subscribing Do hereby Bind and Oblige ourselves strictly and punctually to fulfil, obey, and conform to the regulations, conditions, and provisions herein contained, and also to all such other regulations, bye-laws, orders, and resolutions of this Society as shall be made, agreed to, or enacted in the forms herein prescribed, and that according to the spirit and intention of the same. And that we may the more effectually bind ourselves to abide by and fulfil the intention of this Association, we do hereby (each for himself) give and grant full power, authority, and commission to the President and Secretary of this Society for the time being, for us and in our name, and for behoof of each of us to sign and subscribe in the sedentum books of the Society all such regulations, orders, bye-laws, or resolutions as shall be passed or agreed to in terms of these presents, or the regulations of the Society for the time; Declaring hereby that the same being signed by the President and Secretary, shall render them as binding and obligatory on us and each of us as if we had each signed the same himself before witnesses, and with every other solemnity required by the law of Scotland to render Deeds obligatory, renouncing hereby all objections and exceptions to the contrary, and we consent to the registration hereof in the books of Council and Session or of any other competent Court that letters of hornine on six days' charge, and all other needful execution may pass hereon as effectus and thereto constitute * * * * * * our Procurators.

In Witness Whereof these presents written upon stamped vellum by John Patison, Writer in Edinburgh, are subscribed by us as follows, viz: — William Hutchison, druggist, Foot of Forestier's Wynd, Cowgate; James McDonald, druggist, West Bow; Archibald Napier, druggist, Head of Forestier's Wynd, High Street; William Vivers, chemist, Netherbow; Cumberland Moffat, druggist, Netherbow; Kenneth Mackenzie, druggist, Head of Can'ts Close, High Street; William Kinnaird, chemist, Foot of Horse Wynd, Cowgate, John Moncrieff, apothecary, 17, North Bridge, Edinburgh; George Gray, apothecary, Grass Market, opposite Corn Market (east end); James Maitman, druggist, Foot of Forestier's Wynd, Cowgate; Thomas Boog, apothecary, Head of Canongate; James Gardiner, druggist, Paterson's Court, Lawnmarket; William Dempster, apothecary, opposite Fountain Well, Canongate; Robert Scott, druggist, High Street; Alexander Reid, surgeon and apothecary, St. Patrick Square; Peter Lyon, surgeon and apothecary, James' Court, Lawnmarket.; Ivy Campbell, apothecary, Bull Tumpike, at Edinburgh, the third day of October, one thousand seven hundred and eighty-five years, before these witnesses: John Watson, house painter, Hyndford's Close, Canongate, Edinburgh, and James Spence, writer, Old Bank Close, High Street, Edinburgh, the place, date, witnesses' names, and designations being filled up by the said James Spence.
it were the outcome of a proper course of education. This is what is properly described by Dr. Murray, in a second definition of the verb—"To 'get up' (asubject) hastily for an occasion, without any regard to its permanent retention or educative influence."

Experience has shown, however, that by choosing suitable individuals as examiners—not mere pedants or theorists, but persons with a knowledge of human nature as well as of the subjects in which they are assumed to be experts—such artificial profundity is easily exposed, and the borrowed learning fails to produce results satisfactory to the candidates. As the author of the paper already referred to remarks, the instructors must follow the lead of the examiners, and, if the latter examine badly, the teaching must deteriorate in order to meet their requirements. If they encourage cramming—using the word in its worst sense, as implying the temporary accumulation of a mass of more or less useless facts—then the tutors will resort to cram. "If it were the custom of the history examiners to set such questions as, 'On what day did Lord Sunderland die? What was the state of the weather? Did it rain that afternoon'? I firmly believe the private tutors would use all their energies to devise some plan to meet the difficulty." In the same way encouragement is given to cram of an objectionable nature by the setting of such questions as, "Name all the plants you know in the genus 'Rubus'? Give a list of compounds derived from benzene! What tinctures are prepared with proof spirit?" When questions of this class are the rule at a given examination nothing is easier than for private tutors to prepare their pupils to undergo the ordeal with credit to both teachers and taught, and education properly so-called is at a discount.

Whilst, therefore, the essential difference between a thorough system of education and mere preparation for examination is very great, the fact must be recognised that the existing prejudice against cram is to some extent unfounded, and the method must be tolerated so long as examinations persist. Even when the previous course of training has been most thorough, a final course of cram is in most, if not all, cases found useful, and in many instances of real merit becomes an absolute condition of success, for without it the best trained man may find difficulty in concentrating his genuinely acquired knowledge for examination purposes, whilst his uneducated companion who has simply been crammed for a few weeks or months glibly furnishes replies to numerous questions, and may, perchance, by a stroke of luck manage to satisfy the examiners. There is one remedy, and one only, for this state of affairs, and that is to insist upon a satisfactory course of training being undergone prior to examination. No other plan is likely to remove the difficulty except to a very limited extent, and cer-
tainly no other means will avail to secure that candidates for professional positions shall have been properly educated, and not merely prepared for examination or "crammed." The medical profession has long since accepted this view of the situation, and, sooner or later, pharmacy must needs follow suit.

COD-LIVER OIL AND CHEMISTRY.

The title of Dr. Möller's book—Cod Liver Oil and Chemistry—leads one to wonder whether all chemical substances of pharmaceutical or industrial interest are destined to have books of 500 quarto pages devoted to them. It is to be hoped that in any case the present volume will not be taken as a type, for although monographs on special subjects are always welcome, it would be most undesirable to fill bookshelves with bulky volumes on malt extract and chemistry, Blaauw's pills and chemistry, pepelin and chemistry, and the like. Surely if Dr. F. Pechel Möller feels that he is inspired to write on cod-liver oil and chemistry, it would be both more satisfactory to himself and to his readers if his subject matter were placed in two separate covers, as it must be unusual to find readers who are interested in the new method of preparing cod-liver oil which Peter Möller devised and in stereo chemistry, at one and the same time. Notwithstanding this criticism, it is only fair to admit that there is a very close relationship between cod-liver oil and chemistry, and pharmacists generally would no doubt be glad to have welcomed a book on the chemistry of cod-liver oil, as this subject has recently received much attention at the hands of chemists.

So far as it is possible to form an opinion from a careful review of this work, Dr. Möller does not consider the chemistry of cod-liver oil to be that portion of the scope of his book upon which he is specially qualified to write, as the thirty odd pages devoted to the chemical constitution of the fats and active principles existing in cod-liver oil have been interpolated into the volume and are contributed by Mr. P. M. Heyerdahl. It is these few pages which will be of interest to the readers of the Pharmaceutical Journal, as they form an admirable résumé of the work which has been done on this oil. Ever since Wurster in 1822 first noticed that it was possible to obtain from cod-liver oil an aqueous extract of a viscous yellow substance, acid in reaction and bitter to the taste, chemists have from time to time devoted their attention to this animal product with a view of ascertaining the nature of the various compounds which are present in it. Even at the present time there seems to be a difference of opinion as to what the essential ingredients to which its undoubted beneficial action in phthisis and other wasting diseases is due. Heyerdahl, however, is of the opinion that the active principle in cod-liver oil is the fat itself, and differs from Chapotet, Gautier, and Mourgues, who incline to the view that morrhew or the mixture of ptomaines in the oil confers upon it its peculiar beneficial properties. It seems difficult to believe that the fat per se in cod-liver oil is any better food-stuff than other similar glycerides existing in cream or other oil, but on the other hand it is hard to conceive that the wine of cod-liver oil in which all the fats have been carefully removed should have the same virtues as the oil itself. It would seem better to accept a compromise between these two views and to say that cod-liver oil is a valuable food-stuff in consumption, because some or all of the small quantities of compounds, other than fat, present in it facilitate the assimilation of the cod-liver oil fat. It ought to be easy to ascertain the actual facts, as it is firmly established that cod-liver oil contains from 96 to 98 per cent. of olein, palmitin, and stearin, and any oil containing 25 per cent. of stearin and palmitin with 75 per cent of olein would represent the fats of cod-liver oil very closely. Such a mixture carefully tested clinically against cod-liver oil and the equivalent of morrhew would establish this much debated question.

As might be expected, Dr. Möller has a very unfavourable opinion of the many substitutes which have been proposed, and even the fish oils, such as eulachon oil and dugong oil, are condemned because they are not liver oils, and because they are more viscous, but why viscosity should be a measure of its therapeutic value it is difficult to conceive. Amongst the proposed substitutes for cod-liver oil there is no mention of the viscous hydrocarbons derived from petroleum, which from time to time have been introduced as cod-liver oil substitutes. These might have rightly been adversely criticised as not being glycerides, and therefore not fat-formers in the true sense, but deserve mention in the author's category of substitutes. With regard to the refining of cod-liver oil, the author's well-known process is naturally advocated, and Heyerdahl's researches lend support to the theory upon which it is based. It seems, however, strange that cod-liver oil should not owe its racidity to the presence of free acids, but that the formation of hydroxy-acids is the true cause of the racidity. The aostyl value of cod-liver oil is therefore the practical test according to Dr. Möller as to the therapeutic and consequently commercial value of a cod-liver oil, and oxidation should be prevented as far as possible not only in its manufacture, but also in storing, and especially when in small quantities.

Having discussed cod-liver oil and its commercial preparation, the author devotes the second portion of the book to the consideration of what is called "the law of atomic linking, diagrammatically
illustrated." It begins with the interesting statement that "curiosity is our common inheritance from mother Eve," and finishes with the equally important conclusion that "there are still formidable difficulties to surmount, and many yet unborn theories will come and go before chemists, mathematicians, astronomers, and physicists shall agree on all points, and even then we shall still be far away from that ultimate simplicity which we shall never know—the truth." Between these two sentences is massed the whole of organic chemistry in a novel and startling form. Dr. Möller gives a diagram of each substance which he thinks aids in the elucidation of the subject, but as he omits all general methods of synthesis and analysis, the book is little more than a hotchpotch of organic substances, incompletely described and indifferently classified. The names used are partly English and partly German, but it is impossible to give any adequate idea of the nature of the work without the illustrations, which constitute its one important feature.

ARGON AND THE PERIODIC LAW.

A possible solution of the difficulty which is experienced in allotting a place to argon in Mendeleeff's table, was suggested by Dr. Bohuslav Brauner at a recent meeting of the Chemical Society, in connection with his re-determination of the atomic weight of tellurium. After describing the abnormal results yielded by tellurium prepared in various ways, Dr. Brauner stated that he was inclined to believe that argon was one of a new group or mixture of elements—the "Argon Group"—coming between the last two groups of the periodic system, and observed that, if we assume what we know as tellurium to be a "mixture or alloy or compound" of the true tellurium with "argon No. 4" or "Triargon," it would consist of equal atoms of the two, its formula being \( \text{Te}_2\text{A}_3 \), and its composition corresponding with the atomic weight, 127.71, which he has obtained.

ELECTROLYSIS AND CHEMICAL INDUSTRY.

One of the most striking aspects of the chemical industry of to-day, remarks the Electrical Review, is the encroachment of electrolytic upon the strictly chemical processes. In some branches, electrolysis is described as already confidently fighting for supremacy, whilst, in others, an invasion is threatened. Since, however, the minds of manufacturers are to-day more open to the reception of new ideas than they used to be, and they are willing to profit by experience from the many cogent object lessons they have received in the past, it is not anticipated that the fight will be carried on by them with the weapons of prejudice, and of that conservatism which is held to be characteristic of the English as a race. As relevant to this question the following quotation from the chairman's address at the opening of the new session of one of the provincial sections of the Society of Chemical Industry, is of especial interest. "That there are scores of busy, clever, and eager brains working away, endeavouring to bring these processes (electrolytic processes of making chemicals) into successful operation is patent to us all, and it behoves us to prepare for the invasion of this inventor as for that of all other inventors, and when he has won his spurs and proved his case, to welcome him with open mind, and by timely enterprise to show that we willingly accept and can promptly profit by the invasion of the true and real inventor."

WEIGHTS AND MEASURES ACT.

A Select Committee of the House of Commons is now inquiring into the working of the Weights and Measures Act, and several leading pharmacists are amongst those summoned to give evidence. On page 986 we publish the gist of the evidence given by Mr. Charles Umney on Tuesday afternoon last, and this should prove of considerable interest to our readers as representing the position of leading wholesale drug houses in the matter. It is satisfactory to observe that whilst Mr. Umney is of opinion that British trade suffers no disadvantage by the continued use of imperial weights and measures, he has also expressed his strong conviction that the metric system should be used in the next edition of the British Pharmacopoeia if it is to possess the inter-colonial and international character that ought to be an essential of such a work.

EVENING MEETING IN EDINBURGH.

The document described as "The Bond of the Society of Druggist-Apothecaries in Edinburgh," and reproduced at page 964 of this week's Journal, possesses an especial interest as throwing light on the conditions of pharmacy in the Scottish capital a century ago, and also indicating the steps that had been independently taken there to combine pharmacists into a properly organised body, long before the inception of the Pharmaceutical Society. As pointed out at the Evening Meeting, the old Edinburgh druggists appear to have been considered no whit less important than the apothecaries, and even to have been conceded precedence to some extent by the latter. Altogether, the document now brought to light by Mr. James Mackenzie is of great importance from a pharmaceutical and historical point of view. As usual, the papers read at the meeting were of considerable value and varied interest. Pressure on our space prohibits the whole of them being published this week, but the remainder will appear at an early date.

ANNUAL DINNER.

A full list of Stewards in connection with the Annual Dinner of the members of the Pharmaceutical Society and their friends will be found in the advertisement columns of this week's Journal. Other gentlemen desiring to act as Stewards should send in their names to the Secretary, Mr. Richard Bremerdridge, 17, Bloomsbury Square, W.C., without further delay. The Dinner takes place on Tuesday, May 21, and those purposing to attend should make early application to the Secretary for tickets.
Transactions of the Pharmaceutical Society of Great Britain.

EVENING MEETING IN EDINBURGH.

FRIDAY, APRIL 26, 1866.

MR. J. LAIDLAW EWING IN THE CHAIR.

The fourth evening meeting in Edinburgh of the present session was held in the Society's Hall, 36, York Place, on Friday, April 26, at 8.30.

The minutes of the last meeting having been read and approved, apologies for absence were intimated from Messrs. P. Bos, and J. Neeshit.

The following communications were then read:—

FERROUS PHOSPHATE.

BY GEORGE COULLE, B.S.C.

Before proceeding to state the results of a few experiments, undertaken as indicated at our last evening, meeting with a view to the preparation of ferric phosphates having a higher percentage of ferrous phosphate than the present Pharmacopoeia demands, it may be profitable to give a short historical sketch of the compound as showing the gradual evolution of a pharmacopoeial preparation and the length of time it takes to arrive at an approximate perfection.

Ferric phosphates was not official in the Pharmacopoeias of the London, Edinburgh, or Dublin Colleges; it was introduced into the first edition of the British Pharmacopoeia in 1864, and has retained its place in each successive edition. Previous to 1864 it was official in the U.S.P., its first appearance being in 1840. It was then made by mixing solutions of sulphate of iron and phosphate of soda, decanting, washing with hot water and drying at a gentle heat (it is not stated how the washing is to be done). This manner of preparing it was continued till 1880, when the ferric salt became official, the name still being ferric phosphates. The process now was to dissolve ferrose citrate in water, add sodium phosphate, dissolve, evaporate, and scale. This method is at present official with a slight change in the quantity of sodium phosphate ordered, and instead of being called as has been suggested sodio-ferric citro-tartrate, it is named ferrous phosphates solubilis.

Unlike the Americans, we have adhered as far as we could to the ferrous salt. The formula for its preparation was the same in the 1864 and 1867 Pharmacopoeias, acetate of soda being added to have asetic acid set free in place of sulphuric, on the assumption that the former had less solvent action than the latter on ferrous phosphate. In 1867 the temperature of drying was raised from 100° F, to 120° F., and a standard of ferrous salt fixed, this percentage according to the volumetric determination was 44.75 per cent. of anhydrous ferrous phosphate = 62.75 per cent. of the hydrated salt, Fe₃(PO₄)₂·8H₂O. In the present Pharmacopoeia it is defined as "Ferrous phosphate, Fe₃(PO₄)₂·8H₂O, at least 47 per cent.; with ferric phosphate and some oxide," this percentage is equivalent to 33.5 per cent. of anhydrous phosphate. The sodium phosphate is slightly increased and sodium bichromate is used in place of acetate for the purpose of neutralising the sulphuric acid set free. This valuable suggestion was due to Howie (Ph. J. [3], vi, 807), although Schweitzer (Ph. J. [2], i, 496) suggested the use of carbonate of soda as far back as 1860. This is our present position on the way to finality.

Let us now review the literature of the subject which, unlike that of spiritus aetheris nitrosi, visum ipsecaoumhe, and perhaps a few others, is not very voluminous.

At the same meeting at which Schweitzer suggested the use of carbonate of soda, Gale gave a formula for syrupus ferri phosphatis, his process for the preparation of phosphate of iron was essentially the same as that in the earlier editions of the U.S.P., no allowance being made for the loss of phosphate through its solubility in sulphuric acid.

There have been the usual examinations of trade specimens with the suggestions which inevitably follow. In 1874, Druce (Ph. J. [3], iv, 729), examined ten samples, one of which, however, was arsenate, and another was made by himself and mixed with an equal weight of sugar after drying (my italics). He found this latter sample to be above the pharmacopoeial standard as 104 is to 100. I may here interpolate in passing that this is a very unsatisfactory way of stating results, productive of some little trouble to those who wish to make use of the work done by others for purposes of comparison; they should be given as percentages of the substance that is to be determined in the sample, adding the percentages, if thought necessary, taking the pharmacopoeial standard as 100. Now the standard at that time was 44.75 per cent. of anhydrous phosphate = 62.75 per cent. of hydrated salt, and consequently this sample contained 46.54 per cent. of anhydrous = 65.26 per cent. of hydrated ferrous phosphate. The sample was mixed after drying with an equal weight of sugar; it must, therefore, have contained before being diluted 93.08 per cent. Fe₃(PO₄)₂·8H₂O = 130.52 per cent., Fe₃(PO₄)₂·8H₂O, which I can hardly credit. The probable explanation of this is that the paper having been written before Howie called attention to the action of hydrochloric acid on sugar, in all likelihood heat had been employed to effect solution, hence this high result. In the bond-fide samples he found the strength to vary in percentage of the pharmacopoeial standard from 2 to 100-1, these calculated into percentages of real phosphate are 895 to 44.79 per cent. of anhydrous = 1255 to 62.81 per cent, of hydrated ferrous phosphate. The suggestion made is to mix the freshly washed precipitate with sugar, so that the powder dried at 140° might represent 60 per cent. of ferrous phosphate, and call it ferrous phosphates saccharates.

Cliaand (Chemist and Druggist, xlvii., 277) found commercial samples to contain from 23.27 to 29.35 per cent. anhydrous ferrous phosphate, and makes the same suggestion that Druce made twenty years before, namely, to mix it with sugar and call it ferro phosphates saccharates. But in addition he would introduce several refinements, such as precipitating the phosphate in a saccharated solution, washing with a similar solution, and evaporating to dryness in caeco.

Lothian and Hoseason in 1890 (Ph. J. [3], xxi, 511)
examined twelve commercial samples of ferrous phosphate. The average of anhydrous phosphate was 26.39 per cent.; the poorest sample contained only 9.84 per cent., and the best 44.75 per cent. The latter and one containing 34 per cent. were the only two which reached the official standard. They note that the samples which were bulky and greenish in colour showed a lower proportion of ferrous phosphate than those which were denser and of a more slate-blue colour; this I can fully corroborate. Their recommendation is to use hot concentrated solutions, so as to have the precipitate as dense as possible. This I cannot agree with here, although it is sometimes the correct thing to do; for example, in making the carbonates of magnesia. At the British Pharmaceutical Conference (1875) the President, in discussing Daniels' paper on the "Phosphate Syrups," said he mixed the solutions hot and boiled them, as he got a granular, easily washed precipitate in that way (it was not mentioned if the percentage of ferrous phosphate in the precipitate had been determined) and advocated the use of carbonate as giving better results.

The next paper calling for attention is one by Price in 1876 (Ph. J. [3], vi., 701), where it is first noted that there is a considerable loss of ferrous phosphate, even when using acetate of soda, and that the hot water used for solution causes slight oxidation of the sulphate of iron. His suggestion is to rather more than treble the quantity of phosphate of soda, and to use cold water for dissolving the salts, mix, heat gently for a few minutes, allow the precipitate to settle, throw on calico filter, and wash with cold water. The last and most important paper on the subject I shall refer to is by Howie (Ph. J. [3], vi., 804), read a few weeks after the one by Price. In an exhaustive communication to the North British Branch on "Phosphate Syrups," Howie goes very thoroughly into the chemistry of ferri phosphas. I may here state that I very nearly missed seeing this paper, and only a little by chance after my plan of operations had been settled and my samples made.

Six commercial samples he examined contained 46, 46, 25, 36, 34, 23, and 20.7 per cent. of anhydrous ferrous phosphate. The B.P. standard at that time being 44.75 per cent., the first two alone came up to it, although, according to the 1885 Pharmacopoeia, they would all pass the last one. He stated that the B.P. standard could readily be passed with proper manipulation, and showed a specimen containing 58 per cent. = 827 hydrated.

Briefly put, Howie found that sometimes a bulky precipitate was obtained, and, at others the same chemicals and seemingly (my italics) the same manipulation produced a dense white precipitate, occupying much less bulk than the former. When cold water was used for solution the precipitate was bulky and greenish, with water above 180° F. the precipitate was bulky and, to some extent, gelatinous, and could not at once be washed by submersion. If the temperature be about 130° F., and the soda be added to the iron, the precipitate will be nearly white and will subside rapidly, and it can be thoroughly washed by decantation in a very short time. He thinks the limits of temperature for the formation of this granular precipitate to be from 100° to 130° F.

Therefore Howie recommended (in addition to the use of sodium bicarbonate already referred to) that boiling water be used to dissolve the salts, and that when the temperature has fallen to 130° F., the solution of mixed soda salts be poured into the solution of sulphate of iron with constant stirring. These suggestions have been adopted in the B.P., 1885, only the soda salts are directed to be added separately. He also recommended that the precipitate be washed by decantation, and that the whole operation be conducted rapidly. The facts upon which the order of mixing is suggested are that on pouring the iron solution into the solution of the mixed soda salts, he got a precipitate containing 32 per cent. anhydrous ferrous phosphate, while by adding the soda phosphate to the iron solution and then pouring into the bicarbonate solution, he got a precipitate of which 51 per cent. was anhydrous ferrous phosphate. There is no evidence in the paper that he tried the effect of adding the iron to the phosphate of soda and then pouring in the bicarbonate. He notes that the phosphate is best precipitated in an acid solution, and hence adds the bicarbonate last, but if instead of adding the iron solution to the mixed soda solution as in the first experiment (where the acid is neutralised as soon as it is formed, and hence the precipitation is conducted in an alkaline solution) he had added the iron to the phosphate and then poured in the bicarbonate, he would have got a still higher result, and the precipitate would have been formed in an acid solution.

It was, as previously stated, owing to recent batches of this varying from 47 to 70 per cent. of Fe₂PO₄·8H₂O that my attention was given to the subject. I was extremely astonished at getting 70 per cent., and thought at first a slip had been made somewhere, but repetition of the determination several times gave the same result, and when another lot gave 69.3 per cent. confidence in myself which had received a rude shock was again restored.

The object of my experiments was to ascertain whether washing by decantation was more advantageous than washing on a calico filter, whether the temperature of the solutions had any effect on the oxidation of the precipitate, and whether adding the iron to the soda would result in giving a higher percentage of ferrous salt.

As I stated above, I was not aware of Howie's recommendation to wash by decantation (although it is the method I always employ), still, the work does not go for nothing, as it is useful in fully confirming him on that point. The range of temperature, 100°-150° F., appeared too great, and an attempt was made to fix the most suitable one. The idea of trying the effect of adding the iron to the soda was the result of considering how the scale compounds and some other iron preparations are made. In the case of ferri et ammonii citras, ferri et quinise citras, ferrum tartaratum, ferri peroxidum hydratum, and liquor ferri acetatis fortior, preparations where ferri hydrate is
formed by the action of an alkali on the persulphate, we are in each case explicitly told to add the iron solution to the alkali.

Atfield says in his manual in discussing the scale compounds that this mode of procedure is to obliterate the formation of ferric oxy sulphate. It seemed probable, therefore, that there was any danger of a ferric salt becoming oxidised by being acted on in a certain way, there would be more chance of a more readily oxidisable ferrous salt being oxidised by being treated in a precisely similar manner. It is satisfactory to know that the following experiments fully bear out this view.

Six samples of ferri phosphates were accordingly made, the conditions being varied in each case. The following applies to all the samples:—They were made at the same time, B.P. quantities being employed, they were washed for the same length of time, and were all free from sulphate, the percentage of ferrous phosphate in them was determined with volumetric solution of potassium bichromate freshly made from a recrystallised salt.

When the washing of those that were done on calico was completed, they were simply tied up in the filter and hung in a drying room, where a thermometer placed alongside showed that the temperature was usually about 90°F., it never rose to 100°F. Those washed by decantation were transferred, when the last wash-water was siphoned off from the pots they were washed in to calico strainers, and when drained were tied up and dried in a similar manner. These were also diluted after precipitation with a considerable quantity of water, about one gallon for each. Further details are given in the table and following remarks:

In preparing No. 1 the B.P. directions were exactly followed, the temperature of the solutions before admixture being 130°F. No. 2 was prepared in a similar manner, but the temperature of the solutions was allowed to fall to 100°F. before they were mixed. In the case of No. 3 a pint of water at 110°F. was used to dissolve the sulphate of iron, the phosphate of sodium was dissolved in a pint and a half of hot water, when the latter had cooled to about 110°F. the temperature of the former solution was brought by the addition of half a pint of water of suitable temperature to 110°F., the ferrous sulphate was then added to the sodium phosphate, and finally the sodium bicarbonate dissolved in a little tepid water was poured in. It was washed with cold water.

Nos. 4, 5, and 6 were prepared as Nos. 1, 2, and 3 respectively, but washed by decantation.

There was a marked difference in the appearance of the precipitates while being washed on calico. No. 1 was bulky and gelatinous, and the exposed surface was always of an emerald green colour, while the bulk of the precipitate was of a dirty greenish-white shade. It would not mix well with the washed water owing to its gelatinous nature.

No. 2 was bluish on the surface and bluish-white underneath, it was less bulky than No. 1, and more easily diffused through the wash-water.

No. 3 appeared to be more granular or crystalline than the other two; it was also the densest, and soon became dark blue throughout. It was easily washed with cold water.

The appearance of the lower portion of the precipitates could be seen more readily in those samples that were washed by decantation in a bottle.

When precipitated and diluted, No. 4 settled the most slowly; the precipitate appeared greenish, with a slightly yellow tinge.

No. 5 settled more quickly than No. 4, the precipitate was distinctly greenish.

No. 6 subsided the most rapidly, and the colour of the precipitate was pale blue.

All three gradually darkened during the washing. A fresh quantity of water having been added to them at night and allowed to settle till next morning, I took the opportunity of determining roughly the relative bulk of the three precipitates. They were all in twelve pint pottles of some height and diameter. Precipitate No. 4 measured 2½ inches in depth. With the aid of one of Aspinall's show-cards, I ascertained that the exact shade of the precipitate was sky-blue with a layer of emerald green on the top. No. 5 measured 1½ inch, the mass of the precipitate was a shade darker than No. 4, while the top layer was like that on No. 6, but a trifle lighter. No. 6 measured 1¼ inch, the precipitate was powdery, and appeared bluish, with a darker layer of slate-blue on the top.

The appearance of the samples after drying is also rather interesting. They were all hung up to dry at the same time, and kept in the drying room for the same period, with the exception of Nos. 1 and 4, which required a day more than the others before they were considered dry, and even then No. 1 was hardly quite dry.

This extra time required by Nos. 1 and 4 is owing to the gelatinous nature of the precipitate, which clung most persistently to the adherent moisture. When dried these two were in the form of lumps, necessitating the use of a mortar before they could be sifted. The others were in the form of a fine dry powder, especially Nos. 3 and 6, which did not even require to be sifted.

From the specimens on the table it will be seen that No. 1 is green in colour and No. 6 dark blue, the others being lighter shades of blue than No. 6. It
may be noted that Nos. 3 and 4 have almost the same colour, and similarly Nos. 3 and 5 are almost alike. The yield in the case of Nos. 5 and 6, namely 12 of ferri phosphas from 3 of ferri sulphas, is what I always alight on in actual practice. I have here a sample that was made before the six just mentioned. I meant to prepare them one at a time, but when the appearance of this one was seen, it was deemed advisable to get them all made at the same time. I was under the impression that it had been overheated, but this could not have been the case as it was never above 100° F. It is, as you may observe, a very pale shade of green, and before being rubbed up and sifted it consisted of hard knots of various sizes; it contains only 11-63 per cent. of anhydrous ferrous phosphate. As this sample was a considerably longer time in the drying-room than the others, it must necessarily have been this extra exposure that caused the oxidation.

The above results then which are strictly comparable among themselves, show:—(1) That decantation is superior to washing on calico. (2) That prolonged exposure to the air even at the moderate temperature of 90° to 100° F., has a strong oxidising action on the phosphate. (3) That 130° F. is certainly too high for the solutions to be before mixing. (4) That the range of temperature in the B.P. directions is too great, so that a uniform preparation is not always obtained, and (5) That, all other conditions being the same, a higher percentage of ferrous phosphate can be obtained by adding the ferrous sulphate to the sodium phosphate. Had I known that Howie recommended rapidity of manipulation I would have taken pains to hurry matters, in order to get results higher than I did, which I am sure can with care be obtained. But my manner of operating may be of advantage in this, that it shows how, without any special precautions in this respect, ferri phosphas can be made to attain even unto the standard laid down in 1867.

I would therefore recommend (1) That the present proportions in the formula be retained, being almost theoretically correct. (2) That boiling water be not used to dissolve the ferrous sulphate owing to its oxidising action, but water at about 110° F. be employed, the temperature of the solution being adjusted to that before admixture with the phosphate (as a corollary, the solution of sulphate of iron in the appendix should be made with water recently boiled and cooled). (3) That the ferrous sulphate solution be added to the phosphate, and then the solution of bicarbonate poured in. (4) That after precipitation the mixture be considerably diluted with water. (5) That washing by decantation be adopted. (6) That the maximum temperature of drying be lowered to 100° F., as in 1867. (7) That it be enjoined to conduct the whole process as rapidly as possible, and (8) That the standard be raised to at least 60 per cent. of hydrated ferrous phosphate, Fe₂PO₄·8H₂O.

Mr. Dott said they were much indebted to Mr. Coull for this interesting and elaborate paper. If he were disposed to be critical, there was one sentence that struck him as open to remark. He did not think the analogy between the formation of oxysalts of ferro salts and the oxidation of ferrous salts would hold good. It was not the same thing.

The next communication was on—

THE SOCIETY OF DRUGGIST-APOTHECARIES IN EDINBURGH, 1785.

BY JAMES MACKENZIE, F.S.A. (SCOT.)

Recently there was sent to me a bookseller's sale list containing notice of a document described as "The Bond of the Society of Druggist-Apothecaries in Edinburgh," and bearing the date 1785. I have a distinct recollection that in a casual conversation about the year 1862 the late James Gardner, of 58, George Street, mentioned to me the existence of some such society in Edinburgh at an early period. I took steps to see the document, and as one of the signatories was James Gardner, the father of James Gardner, of George Street, who founded the business in 1778 in the Lawnmarket, it occurred to me that probably this was the society mentioned in 1862. It would appear that the document which has come to light unexpectedly, and which I now produce, written and signed upon what is termed "this sheet of stamped vellum," was sold at an auction sale along with a great many other effects, and thus came into the hands of the bookseller from whom I obtained it. The document is written by John Patison, who was a well-known writer in Edinburgh at that time, and a year afterwards, in 1786, an additional clause is added by James Spence, writer, Old Bank Close, High Street. It is highly probable that, following the usual practice of those days, John Patison, and afterwards possibly James Spence, acted as Secretary to the Society, and this bond would be preserved in the office of either the one or the other and probably cleared out, many years afterwards, along with other old papers. I have made search and it does not appear ever to have been registered in the court of session as provided for in the bond, but that was a very frequent occurrence in regard to societies of this kind. I have been able to trace each of the eighteen persons who originally signed the document as well as the witnesses who attest it, and their addresses are appended.

The names and addresses of those who sign the bond (which is reproduced at page 986) are verified by the Edinburgh Directories of the period. To those of us who are members of the Pharmaceutical Society and reside in Edinburgh, this document has a special interest, proving the advanced state of pharmacy as carried on in our city, and the aims and thoughts which occupied the minds of the men who represented our calling at so early a period. For some account of the position of pharmacy in Edinburgh, I would refer you to a paper read by me at an evening meeting in Edinburgh in 1871, entitled "Pharmacy in Edinburgh in the Olden Times" (Pa. J. [3], vol. ii., p. 414).

In process of time the art of pharmacy was left in the hands of the druggists, a class of men who, though there was no rule, were generally those who
had served a regular apprenticeship of not less than five years. I submit a copy of the indenture usually employed, dated Perth, May 25, 1720. In this case the master was a "chyrurgeon-apothecary." In 1785 there existed in Edinburgh a class of men known as apothecaries, who I take to have been such as had been indentured to a surgeon-apothecary, paying probably a higher fee, but who did not differ from the druggist in so far as the sale of drugs was concerned. No examination was compulsory, and it was the ability to produce a completed indenture of apprenticeship which constituted the certificate of competency in those days. We have a side-light thrown on the condition of things by a description of the mode in which a diploma was obtained at the Surgeons’ Hall about ten years later than this, as given in the following words: "In 1786 I applied at the Surgeons’ Hall for examination in order to obtain a diploma. I was told they examined students once a month when more than one applied. Five students appeared for examination, and remained in the waiting-room till called in singly. After being questioned for about the space of ten to fourteen minutes, he was asked to retire, but immediately recalled, when he returned to his fellows to say he had been accepted."

The relative position of the druggists in 1785 is evident by the fact that they are placed first in the new Society, while the bond itself is interesting evidence of the growing desire to advance pharmacy beyond a point which had yet been thought of, and is, so far as I can discover, the first of the kind existing in our land.

It is also worthy of notice in passing that at the first meeting held in Edinburgh, along with friends from London, in 1851, to consider the formation of a Society for like purposes, which we now know as the Pharmaceutical Society of Great Britain, Mr. James Gardner was present at that meeting; he was the son of the Mr. James Gardner who signed the bond and had been apprenticed with his father at the little shop at the head of Paterson’s Court, Lawmarket, who would no doubt refer to the Society of Druggist-Apothecaries existing in Edinburgh, he being a member of this older Society; and it is a curious circumstance that the North British Branch of the Pharmaceutical Society was modelled upon the same lines; indeed, it is questionable if the Pharmaceutical Society was not shaped after this pattern, and that Mr. Jacob Bell himself discovered in this a new "northern light." For every principle of the present Society is to be found in this one, so much older, alike in its unity, training, and examination, trade interests, and regulation. The office bearers are an exact copy, and its aims identical. I am inclined to think that at the time when some of our friends in London began their reform on our North British Branch of the Pharmaceutical Society, had this document been discovered before then, some of us who had a hot hand in that fight, which has turned out so well for all parties, would have stood upon our prerogative and showed that our office bearers were practically a continuation of an older society, and our answer to all attempts at change would have been what Dr. Chalmers is credited with saying on another occasion, "Retract not a hair's breadth."

It may also interest some to know that in 1774 there were about twenty druggists in Edinburgh, apart from the apothecaries and surgeon-apothecaries so general at that time in this city. These chiefly clustered round the High Street, Cowgate, and Canongate, nor need we be surprised at this, as the well-to-do citizens lived then in that locality. But great changes took place towards the close of last century, when many removed to the new town, or northern portion of the city. The very few shops in the old locality which remain may have said of them, "I alone am left to tell the tale."

It is no great stretch of imagination to suppose that these friends of pharmaceutical reform convened their meetings in the house of their friend, John Stewart, vintner, Old Fishmarket Cloze, which would be one of the best inns in the city at that time, and a regular place for meeting on such occasions. Indeed, such an inn retained a high reputation in this close till within recent years, when it was closed. The lawyer who drew the bond, Mr. John Patison, was a man of note in his day.

Little can be gathered now as to the druggists themselves. I find that there were some of them who took part in the public business of the city. That they were men of good position and character we have no doubt. There is still a trace of some of their businesses. Mr. John Moncrieff being so worthily represented in the same shop by Messrs. J. F. Macfarlan and Co.

Mr. Scott left the High Street for the South Bridge, and known long after as the firm of Scott and Orr, still represented by Messrs. Symington and Fraser. While Mr. Gardner has his name before us in the well-known firm of Gardner and Ainslie.

I find that there were others in business who, for some reason, did not join the Society. One in the Luckenbooths round St. Giles Church, named James MacCaulay, the following advertisement, cut from the Edinburgh Advertiser, of 1797, shows the last of his business:

TO SURGEONS AND APOTHECARIES.

THE WHOLE MEDICINES in that Shop lately possessed by Mr. James M’Caulay, druggist, Luckenbooths, Edinburgh, together with upwards of £200 Sterling of additional articles, which have been commissioned within these few weeks, are now selling off far below prime cost, for Ready Money only. Also, a considerable assortment of Glass, Shuttles, and other apparatus for Drugists and Chemists. As the whole must positively be sold off before the term of Whitaunday next, great bargains may be expected, and it is well worth the attention of any person who propose commencing business in that line, as they may have not only the whole Medicines and Apparatus, but also a lease of the Shop. Not to be repeated.

And now, in conclusion, I think we are warranted in saying that we are glad to have this additional light cast upon the pharmacists of our old city, who were moved by so laudable a desire to improve the whole surroundings of their daily occupation, and to raise the business of pharmacy at a time when such a task was much more difficult than in our day. I think
we may well feel proud of those men, and it is our duty to hand down their names and conduct to the generations that are to follow us.

The CHAIRMAN said they were greatly indebted to Mr. Mackenzie for his interesting account of old Edinburgh and the production of this ancient document for their inspection. He had had the privilege of reading the document carefully, and he was much struck by the precession of these former pharmacists of Edinburgh. Some of the things they sought after were still matters for discussion, among them such as for instance the power to expel offenders from their ranks. The regulation of prices was one also with which most of them would sympathise. The idea of a fine for non-attendance at their meetings would be an excellent means of securing a large attendance. He would re-echo Mr. Mackenzie’s concluding sentences. They should all feel proud of the position their forefathers occupied and endeavour to hand down to their successors the worthy traditions of which they were the heirs.

Mr. MACLAREN said it was very interesting to note how history repeated itself. By this communication he had been reminded of a meeting held in a hotel seventy-seven years afterwards in 1862, at which Mr. James MacKenzie, then of 52, North Bridge, was in the chair, and at which the Association of Assistants, known as the Wilsonion Association, was formed. Mr. MacKenzie was elected the first president on the motion of Mr. G. H. Laird, seconded by Mr. R. S. Brown, now secretary to the Grand Lodge of Freemasons, Edinburgh. Mr. MacKenzie was the first president, and he (Mr. MacLaren) was the last. On receiving notice of this meeting, he had examined some old papers and found the old minute book of the Wilsonian Association, which he had now much pleasure in handing over to the library of the Society in Edinburgh.

Mr. DOTT said he noticed a remark by Mr. MacKenzie that this Society had been incorporated. He would like to know in what way that had been done.

Mr. RUTHERFORD HILL said this was an interesting and important contribution to the history of pharmacy in this country. They had not been able to discover the sederunt book mentioned in the document, and could not tell how long this society had existed, or what kind or amount of work it had done. At the same time the significance of its formation was considerable as an indication of the state of matters in Edinburgh at that time. In 1794 a Pharmaceutical Association composed of apothecaries was formed in London for the express purpose of terminating the druggists, whom they regarded as bitter enemies and intruders. It was not till 1802 that the apothecaries and druggists of London were able to coalesce and frame a joint petition against the oppressive proposals of the medical authorities. Evidently in Edinburgh, so early as 1785, the relationship between apothecaries and druggists was of a much happier kind, and the relative importance of the druggists was shown by the fact that the first person who signed this document belonged to the latter class.

Mr. MACKENZIE, in reply to Mr. DOTT, said he used the word incorporated in a literary sense. There was no evidence of a legal incorporation.

(To be continued.)

Proceedings of Societies in London.

CHEMICAL SOCIETY.

A meeting was held on Thursday, April 25, the newly elected President, A. Vernon Harcourt, F.R.S., in the chair. The following papers were read:—

THE ACTION OF NITROSYL CHLORIDE ON AMIDES.

BY PROFESSOR TILDEN, F.R.S., AND DR. M. O. FORSTER.

In continuation of their study of the reactions of nitrosyl chloride with organic bodies, the authors have investigated its reaction with amides, and find as a general rule that the reaction proceeds as follows:—the amide is converted into the corresponding acid chloride by double decomposition according to the equation

$$ RCONH_2 + NOCl = RCOCl + H_2O + N_2 $$

where R is a radical as methyl, etc. Water, however, hydrolyses acid chlorides, forming the acid and hydrogen chlorides, but if the nitrosyl chloride be used in excess, this secondary reaction does not occur. The action of this reagent on oxamide (CO-NH$_2$)$_2$ is exceptional, since all attempts to bring about the reaction have failed, and it is suggested that this may be due to the fact that oxamide is really a closed chain compound containing pentad nitrogen according to the accompanying formula. Prof. Sakurai (Proc. Chem. CO-NH$_2$, Soc., 1894, 90) has recently urged the adoption of the formula now shown for CO-NH$_2$ glycocine (Erlemeyer and Sigl. Ann. CO-O 179, 349), thus viewing it as an internal ammonium salt with analogies to betaine.

With nitrosyl chloride, however, glycocine undergoes the general reaction, and yields chlorosuccinic acid, thus acting as an amide:—

$$ CH_2-NH_2-COOH + NOCl = CH_2-Cl-COOH + H_2O + N_2 $$

If glycocine were a closed chain compound, as suggested above, nitrosyl chloride could only react after breaking down the ring, and it does not thus react with an analogous compound with a closed chain, viz., hippuric acid. Glycocine CH$_2$NH$_2$CONH$_2$ must therefore be regarded as CO-O hippuric acid.

THE ACTION OF NITROSYL CHLORIDE ON ASPARAGINE AND ASPARTIC ACID; LEVO-ROTATORY CHLOR-SUCCINIC ACID.

BY PROFESSOR TILDEN, F.R.S., AND H. J. MARSHALL.

The action of nitrosyl chloride on the amido-acid and corresponding amide of succinic acid was now investigated. If levo-rotatory asparagine (C$_2$H$_5$NH$_2$.COOH.CONH$_2$) is heated with liquid nitrosyl chloride, a crystalline solid is obtained (M.P. 172°), but a better method of preparation is to dissolve the asparagine in concentrated hydrochloric acid and pass...
gaseous nitrosyl chloride through the solution, when a precipitate is formed, which after filtering off is found to be fumaric acid, and from the filtrate, chloro-
succinic acid (M.P. 174°) is obtained. It was found that both asparagine and aspartic acid yielded
fumaric acid, and the amount formed depended on the temperature at which the reaction occurred.
The fumaric acid is probably formed by the formation of an additional compound, and then
splitting off of nitrogen, water, and hydrogen chloride.

\[
\begin{align*}
\text{CH}_4\text{COOH} + \text{NOCl} &= \text{HCl}\cdot\text{CHCOOH} \\
\text{CH}_2(\text{NH}_2)\text{COOH} + \text{HCl} &= \text{NO-NH}_2\text{CHCOOH}
\end{align*}
\]

The chlorosuccinic acid is formed by the general reaction, and is levo-rotatory to a corresponding
degree to the dextro-rotatory acid previously described (\(\alpha^\circ = \pm 29.7^\circ\)).

**On a Property of the Non-Luminous Atmosphere Coal-Gas Flame.**

**By L. T. Wright.**

The ordinary non-luminous gas flame can be separated into two flames by means of the apparatus
described by Smithells (J. C. S., 1892, lixi., 204). In order to study the properties of the inner flame, the
author uses a long combustion tube with a supply of air and gas at one end, the flame is ignited, and then
the inner flame can be led down the tube by heating with a bunsen flame and moving the flame
slowly along the tube, when the inner flame follows the bunsen like a needle a magnet. With
the flame in this position the products of combustion of the inner flame were examined, and it was
found that using a mixture of 23 per cent. of coal-gas and air that the combustion is more complete, according
to the velocity of the gas supply. It was also found that the surface of the flame does not increase with the
velocity, although the outer flame does so increase; the inner flame is, however, the hottest.
Sometimes the inner flame begins to vibrate as the velocity of the gas supply increases, and this may
start an explosive wave, thus causing fatal results.

**Dioortho-Substituted Benzoic Acids.**

**By J. J. Sudborough, Ph.D.**

Meyer and Sudborough (Ber., xxvii., 1580, 3146) have previously shown that dioortho-substituted acids of the
type (where R may be Br, Cl, CH₃, COOH, NO₂) do not yield esters by the general method of passing hydrogen chloride
through an alcoholic solution of the acid.

The esters can, however, be prepared by other general methods, as the reaction of the silver salt
and alkyl iodide. The acids of the higher homologues, as CH₃-R-CH₂-COOH (1, 2, 3), however, yield esters
by treatment with hydrogen chloride in alcoholic solution. A large number of the acid chlorides, the
isomeric mono-, di-, tri-, and one tetra- brom-acid chlorides were prepared, and the conditions of hydro-
lysis studied. It was found that, as a general rule, the ortho-compounds were hydrolysed with difficulty when
water was used as the hydrolysing agent, and that the para- and para-compounds were more easily hydrolysed.
When the hydrolysis was effected by pure sodium hydrate, the same result was obtained, the ortho-
and particularly the dibromo-compound in the ortho position being most
stable, and only hydrolysed with difficulty. Similar experiments with the
dinitro-acid chlorides did not yield satisfactory results owing to other changes. Meyer states
that the ortho-compounds in the mono-substituted ethers are formed more slowly than the isomeric meta- and para-compounds, and are more slowly hydrolysed.

**Hydrolysis of Aromatic Nitrites and Acid Amides.**

**By J. J. Sudborough, Ph.D.**

For the preparation of the acid chlorides mentioned in the preceding paper, it was necessary to first
prepare the corresponding nitriles, and these were prepared by Beauveault's method, by diazotisation by
Sandmeyer's method. In the preparation of these compounds two intermediate acid amides were formed, and the action of hydrolysing agents noted.
Of two isomers of formula C₆H₅BrBrCONH₂ it was found that hydrolysis and subsequent formation of
the acid was effected by 80 per cent. sulphuric acid with the isomer (1), containing one halogen in
the ortho position to the CONH₂ group, but that when they (2) were both in the ortho position to the acid amide group no hydrolysis occurred.

\[
\begin{align*}
\text{CONH}_2 &\quad \text{COHN}_2 \\
\text{Br} &\quad \text{Br} \\
1. &\quad 2.
\end{align*}
\]

Two exceptions were also found of nitriles where hydrolysis was not effected by sulphuric acid, viz.:

\[
\begin{align*}
\text{CN} &\quad \text{CN} \\
\text{Br} &\quad \text{Br} \\
\text{Cl} &\quad \text{Cl}
\end{align*}
\]

the 1, 2, 3 dibromo-benzo-nitrile, and 1, 2, 3 dichloro-
benzo-nitrile.

**Action of Sodium Ethylate on Deoxybenzoic.**

**By J. J. Sudborough, Ph.D.**

It is found that when sodium ethylate reacts with
deoxybenzoic (phenyl-benzyl-ketone) a sodium compound is formed, which, with alkyl iodide, undergoes
double decomposition according to the equations—

\[
\begin{align*}
\text{I.} &\quad \text{C}_6\text{H}_5\text{CH}_2\text{CO-C}_6\text{H}_5 + \text{NaOC}_2\text{H}_5 = \text{C}_6\text{H}_5\text{CHNaCO-C}_6\text{H}_5 + \text{C}_2\text{H}_5\text{OH} \\
\text{II.} &\quad \text{C}_6\text{H}_5\text{CHNaCO-C}_6\text{H}_5 + \text{C}_2\text{H}_5\text{I} = \text{C}_6\text{H}_5\text{CHC}_6\text{H}_5\text{CO-C}_6\text{H}_5 + \text{NaI}.
\end{align*}
\]
When nitro-benzene is used in place of deoxybenzoin it is found that one nitro-group in tri-nitrobenzene is easily acted on by sodium ethylate yielding an azo-compound, but no such reaction occurs with sodium methydate.

CHEMISTS ASSISTANTS' ASSOCIATION.

At the meeting of this Association on April 25, the following paper was communicated:—

ESSENTIAL OILS IN THEIR RELATION TO THE BRITISH PHARMACOPOEIA AND TRADE.

BY JOHN C. UMNEY.

(Continued from page 492.)

Coriander Oil. — No essential oil official in the British Pharmacopoeia has been more adulterated during the past two years than that of coriander. The abnormal price of the seeds during last year being to a great extent the cause of this. With a more abundant crop of seed, the quality of the oil has improved, although such change may also be attributed to the readiness with which such sophistications were detected.

The principal adulterant of the Continental distilled coriander oil has been orange oil, but in one sample examined the adulterant was found to be turpentine. These samples, bearing the label of their distillers, have been carefully preserved, and their characters are included in a table with the pure oils to show their gross adulteration.

The English and pure German samples examined showed only the slightest variations, both being readily soluble in three volumes of alcohol of 70 per cent., and possessing a specific gravity of from 0.870 to 0.885 at 16°C., these being principally the requirements of the United States Pharmacopoeia. Neither of the adulterated samples answered the former requirement, whilst the oil adulterated with orange oil examined had a specific gravity of only 0.864 at 16°C.

The optical rotations of the pure English and German distilled oils examined have been from +7 to +14, whilst the oils adulterated with orange oil have had much higher rotations—up to +24—and the turpentine-adulterated oil was found markedly levo-rotatory. The characteristic viscosity of the oil is much lessened also by the two adulterations mentioned, and is sufficient in itself to cause suspicion.

The annexed table indicates the characters already alluded to, whilst it will be noted in the case of the pure oils 50 per cent. distill between 190–200°C., consisting largely of coriandrol, which boils between 194 and 188°C.

From the above it is suggested that the oil should answer the following requirements:— Specific gravity.—0.870–0.885 at 16°C.

Solubility.—In three times its volume of alcohol of 70 per cent.
Rotation +6 to +14.
Not less than 40 per cent. should distil between 190 and 200°C.

Dill Oil.—This oil, which is not official in either the United States or German Pharmacopoeias, is somewhat extensively employed pharmaceutically in this country, and is in far greater demand than many of the other essential oils official in the British Pharmacopoeia.

The samples examined show very considerable variation, and in order to make accurate comparisons of some it was found necessary to distil some English fruit obtained from plants grown in Lincolnshire.

This oil was found to have a specific gravity of 0.9148 at 16°C., an optical rotation of +75°, and to yield on fractional the following percentages:—

Below 185°C. 8 per cent.
185–210 28
210–220 12
220–230 50
Above 230 2

Carvol, which boils at 240°C., is therefore present to the extent of 40 to 50 per cent.

These figures are very different from those obtained from a sample of German distillation, which had a specific gravity of 0.9002 at 16°C., an optical rotation of +70–75 in 100 mm. tube, and yielded the following percentages on fractionation:—

Below 185°C. 26 per cent.
185–200 27
200–220 25
220–230 17
Above 230 5

It is necessary to call attention to the high percentage of low boiling terpenes in this oil also and to the small percentage of carvol contained in it, as evidenced by the small proportion boiling between 220 to 230°C. The possible abstraction of a portion of the carvol from this oil and increase in relative proportion of the other constituents has been referred to under caraway oil.

It is interesting to put on record the examination of a sample of oil of English distillation, from East Indian fruits—draws the specific gravity of 0.9184 at 16°C.

The optical rotation.—+47°.

Below 185°C. 8.5 per cent.
185–210 53
210–220 7
220–230 10
230–250 17
250–280 18
Above 280 8.5

The proportion of carvol is therefore very small indeed, whilst the fraction boiling from 250–350°C has a specific gravity of 1.078 at 15°C., to which the high gravity of the oil is due. Schimmel and Co. have observed the separation of a body heavier than water in the distillation of a sample of oil from these

Coriander Oils.
fruits. The principal constituents of the oils from English and German fruits are nearly identical and similar to that of caraway, the percentage of carvol, however, falling lower than in that oil. The aroma of this oil is somewhat modified by the presence of small quantities of other bodies, and is preferred for sweetness to that of caraway, although doubtless its carminative action is less marked, owing to the smaller proportion of carvol it contains.

It will probably be deemed desirable on the former account to retain this oil in a new British Pharmacopoeia, in which case the following are suggested as characters and tests.

The oil distilled from English or German fruits, specific gravity 0.915 to 0.925 at 15° C., not more than 15 per cent. should be below 0.825, C., nor less than 40 per cent. above 220° C. Dextro-rotatory to the extent of not less than +70° in a 100 Mm. tube.

**Eucalyptus Oil.**—The description of this oil contained in the B.T., 1885, vi., distilled from the fresh leaves of *E. globulus*, and probably other species of eucalyptus, has been the means of introducing into British pharmacy a great variety of oils differing very markedly in physical characters. This wide difference in substances answering to one generic name, "eucalyptus oil," has led to considerable discussion during the last ten years, and as by far the greater proportion of it is used as a convenient prophylactic against influenza, etc., by the public, who must of necessity be ignorant of the possible differences that genuine oils may possess. The oils, for medicinal use, principally met with in commerce, during the past few years have been:—Globulus oil of Australian, Tasmanian, Spanish and French origin, and *amygdalina*, *dunas*, *oleosa* (cneorifolia) and, latterly, *odorata*, distilled in Australia.

Out of a great number (nearly 100) of samples examined during the past four years, only two were found to be adulterated, the substances employed being in one case petrolatum and in the other camphor oil, from which the greater part of the saffrol had been removed. The specific gravities cover a wide range—

- The lowest being a sample of "amygdalina" oil, 0.8223 at 15° C., the highest being a sample of Spanish globulus oil 0.923 at 15° C. The optical rotations vary from +81° to +95° in a 100 Mm. tube, +4°1 to +75° in the case of one "amygdalina" oil examined, whilst in the case of some "globulus" oils +17° has been the rotation observed. In the finest globulus oils, both French and Australian, the rotation observed has been very slight, from +1° to +4°, the sample most nearly resembling that of eucalyptus oil of the month of October in the South of France, and from which no fraction had been removed, containing none, whilst the highest—a sample of "cneorifolia" oil—contained 64 per cent. The percentage of eucalypt appears, moreover, to vary very considerably from year to year at which the oil is distilled, a sample of French globulus oil, distilled in the spring in the same district, yielding as much as 60 per cent. These percentages are possibly somewhat lower than might be obtained by the process, which has been patented for making the extracts from oil of peppermint, and consists of the separation of the eucalypt in phosphate; as a means for the exact assay of eucalypt oil this process has not afforded me satisfactory results. Many samples of commercial eucalypt examined by this method have been found to contain considerable proportions of "other" extractive constituents of the natural oil.

Dr. Attfield, speaking at the evening meeting of the Pharmaceutical Society (Ph. J., December 15, 1894, p. 507) on this subject observed, "Physicists and chemists have done even more than could have been expected of them in connection with eucalyptus oil, they have gone ahead of the pharmacists and the next movement ought to be made by the medical pharmacologists," and this accurately sums up the present position of our knowledge of this oil. What remains to be decided by them is therefore:—

1. Has eucalyptus oil any medicinal value as a prophylactic against "influenza" malaria, or as an antiseptic?
2. If value exists in any such direction, to what constituent of the oil is it to be attributed?
3. If attributed in the main to "eucalyptol," is it advisable to introduce that pure substance into a new edition of the British Pharmacopoeia?

Until these questions are answered, it seems undesirable to suggest the inclusion in the new British Pharmacopoeia of the oil of any particular variety or to frame any sufficiently comprehensive "characters and tests." It may be noted that in the United States Pharmacopoeia the oils of *globulus*, *oleosa*, and "other species" are official, the majority of "amygdalina" oils being excluded by the wording of the nitrite phellandren test, whilst in the German Pharmacopoeia eucalyptus oil is unofficial. It may be noted also that in the recommendations of the Victorian branch of the British Pharmaceutical Association the "amygdalina" variety is omitted under "oleum eucalyptol" and the requisition is also added that the oil "should not give the phellandren reaction."

**Fennel Oil.**—The two principal varieties of this oil met with in trade are known respectively as those of "bitter" and "sweet" fennel respectively. The latter commands a much higher price than the former, and is that usually employed in pharmacy. It is official in the U.S. and German Pharmacopoeias, and although unofficial in the B.P., is in greater demand than many essential oils that find a place in that work.

The specific gravity of this oil states by both the United States and German Pharmacopoeias to be not less than 0.960 at 15° C., whilst reference is made in the former to the solidification of the oil at between 5° and 10° C., but "occasionally," is added, "it remains liquid at a considerable lower temperature."

For the purposes of this note, I have distilled a sample of oil from seeds obtained by way of Marseilles, and made careful comparison of its principal characters with those of a twice rectified sample of German distillation, the results being tabulated below. It may be noted that only the former solidifies at a temperature of 10° C. The fractionation of both samples which shows considerable discrepancy, and may be due to the German oil being distilled from any other variety of seed, appears to indicate the presence of considerable proportion of the body described as liqui anesthol (B.P. about 225 to 236° C.), other compounds in the big fraction (230 to 235° C.) which solidify on cooling, showing also the presence of crystallisable anesthol, the boiling point of which is 254° C.

**Bitter Fennel Oil.**—The price of the oils met with in trade under this name affords a good indication of their value. The examination of one of these oils has been conducted, the admixture of a considerable pro-
portion of turpentine being evidenced by the specific gravity rotation and results obtained by fractionation. Specific gravity—8888 at 135°C.

Optical rotation—3-76.

Fractionation: Below 176°C............ 76 per cent. 175-205 .......... 10-8
Above 205 ............... 13-2

The characters and tests of the U.S. Pharmacopoeia appear to be those therefore of a good fennel oil, the specific gravity of not less than 0.960 being the most important requirement, whilst the optical rotation of the oil, viz., from +6 to +20 in a 100 Mm. tube might also be added.

Juniper Oil.—This oil, which has for many centuries been held to be of medicinal value, is one which varies considerably in character, due possibly to some extent to the condition of the berries from which it is distilled, and also to the age of the oil.

The article on "Oil of Juniper" in the series of communications on "The Terpentines of Resinous Products of the Conifers," by Dr. Julius Morel (PA. J. [5], VIII., 956), contains considerable information and a typical chemical analysis of this oil, and shows no great discrepancy with our knowledge of its constitution at the present time.

The British Pharmacopoeia adopts the views put forward by Morel, in requiring that the oil "shall be distilled from the fully grown green unripe fruit of Juniperus communis," which, according to that writer, yield a larger percentage of volatile oil and of lighter specific gravity. The United States and German Pharmacopoeias, however, make no special requisition as to the condition of the berries for distillation, the latter giving no specific gravity, whilst the former states from 0.950 to 0.980 at 15°C.

A sample distilled over two years since from ripe berries was found to have a specific gravity of 0.961 at 15°C, whilst freshly-distilled oils varied between 0.963 and 0.980 at that temperature.

The specific gravity of the oil varies according to the relative proportions of pinene and cadinene, its principal components, which have a specific gravity of 0.956 and 0.926 at 15°C, respectively, but the conditions on which those in proportions depend cannot be said to have been determined with certainty.

The following figures were obtained by fractionation of a freshly distilled oil from dried berries, which had a specific gravity of 0.9745 at 15°C.

A sample of twice rectified oil had a specific gravity of 0.9633, and contained 15 per cent. boiling above 265°C.

The optical rotation of this sample was 6-125, whilst that of the same sample previously referred to was 9-55.

All the oils were very strong and their weights, coming four times their volume of equal parts of alcohol 92 per cent. weight, rectified spirit and alcohol absolute.

It is questionable, therefore, whether in the new edition of the British Pharmacopoeia the statement as to the condition of the berries for distillation should not be omitted, whilst the following characters and tests might be included:

Specific gravity—885-3-990 at 15°C.

Optical rotation.—Not exceeding—10° in 100 Mm. tube.

Solvency in alcohol.—Should be soluble in four times its volume of a mixture, equal parts of rectified spirit and absolute alcohol.

Juniper Wood Oil is also largely used in this country, but although possessed of a trifling extent of the aroma of the berry oil, its use should be discouraged.

Societies in London. [Pharmaceutical Journal] 797

Lavender Oil.—It cannot be said that the investigations of Bertram and Walbaum (Journal für praktische Chemie, 1892, p. 590) and Semmler and Tiemann (Berichte, 1893, p. 1180) have led to a complete elucidation of the relation between the chemical constitution and aroma value of English and French lavender oils. These investigations have led to attempts to base the value of lavender oils on the percentages of esters, viz., linyl acetate, linyl butyrate, and geranyl acetate, which the oils contain; it is found, however, that the results obtained by such ester determination are at complete variance with all hitherto accepted opinions of the value of the chief esters being the varieties of oils so far as delicacy of aroma, and consequently, perfumery value is concerned. It seems probable, therefore, that the presence of free linalool, cineol, and possibly other bodies considerably modifies the aroma and thus renders the determination of the esters, based on the free alcohol, of doubtful accuracy. There can be no question, however, as the results which follow indicate, that as a means of comparison of the purity of the oils of the same class it is of considerable value, more especially as indicating the admixture of oil from Lavandula spica ("aspio" or "spike") which is most common in the cheaper grades of French oils.

English Lavender Oils.—Those examined have a specific gravity of from 0.885 to 0.900, at 15°C, and include samples distilled in the Mitcham district from the year 1894 to 1891 inclusive. Although the oils of earlier distillation possess the highest specific gravities, this change does not appear to affect the sweetness of the oil, the odorous constituents of the oil being presumably unaltered. All the samples examined dissolved readily in two to three volumes of alcohol of 70 per cent. strength, the rotations varying between +7 and +9 of 100 Mm. tube.

The percentage of total esters contained in Mitcham oils is stated by Schimmel and Co. to be about 7 per cent., but I have found as much as 9-5 per cent. in one sample distilled at Ewell, Surrey, in 1891.

By fractionation a considerable proportion of cineol was obtained, and it is to be remembered that the determination of this oil is included in a table showing a comparison of various types of lavender oil.

French Lavender Oils.—The specific gravity of the genuine French oils appears to vary within very narrow limits, viz., from 0.944 to 0.964, the purest oil being obtained from the lavender grown at high altitudes (4000 feet) and free from admixture with oil of Lavandula "aspio." The poorer qualities distilled from lavender growing at lower altitudes more often possess a higher specific gravity, due to the presence of "spike" lavender, the oil of which has a higher specific gravity than the pure lavender oil, and is consequently referred to the "spike" lavender group. These oils vary in specific gravity from 0.964 to 0.975, the pure "spike" being 0.964 to 0.975.

Mixtures of lavender and "spike" oils therefore usually possess very slight rotatory power, sample No. 4 being probably a mixture of these oils in nearly equal proportions.

As previously mentioned the ester percentage affords an excellent means of comparing lavender oils of the
same class. As moreover, "spike" oil contains practically no esters, this determination, combined with the other physical characters already alluded to, shows almost conclusively when admixture of the two oils has been practised.

The highest percentage of ester obtained in examination of many samples of the finest French lavender oil has been that included in the table, viz., 37-1, but larger percentages, up to nearly 40 per cent., have been obtained. I cannot endorse the opinion of those who maintain, allowing their sense of smell to be biased by their chemical knowledge and determination of that which constitutes a part only of the odorous constituent of lavender oil, that the Mitchum oil "enjoys an undeservedly high reputation, and that as regards aroma it cannot compete with a fine French distillate." (Schimmel and Co., report, October, 1894.)

The ester percentage in sample No. 4, the rotation and gravity of which has already been noted as indicating a mixture of about equal parts of lavender and spike oils, is only 15-4 per cent. All of these oils dissolve readily in twice to three times their volume of 70 per cent. alcohol (by volume).

**Spike (Lavandula spica) Oils** are largely used in this country for veterinary purposes and in soap perfumery, and for that reason, as well as to indicate their bearing on the purity of commercial lavender oils, the results of the examination of two typical samples, one pure and the other grossly adulterated, has been appended to my note on this subject.

**Lavender Oils.**

It will be observed that in the case of the pure oil the specific gravity is higher than that of lavender oil, whilst the optical rotation is in the opposite direction. It is readily soluble in alcohol of 70 per cent., the ester percentage being practically nil. The impure oil (No. 2) consists almost wholly of turpentine, 88 per cent. boiling below 180°C, and is, of course, far less soluble in alcohol of 70 per cent.

I would suggest, therefore, in the case of this oil (as well as that of peppermint) the requirement "distilled in Britain" be adhered to, the following characters and tests being added:

- Specific gravity from 885-900 at 15°C.
- Optical rotation. — 8 to — 10.
- Dissolves in three volumes of alcohol of 70 per cent. (by volume)

**Mustard Oil.** — The essential oil "distilled with water from black mustard seeds" is the only one contained in B.F., 1885, to which a boiling point is ascribed, viz., about 258°C. (174-8°C), this character being certainly the last one would of necessity adopt for examining the purity of the oil on account of the difficulty of condensing its penetrating vapour.

Two varieties of the oil are met with in trade, viz., the "natural" oil and the "synthetic" oil, the latter being at the present time about 20 to 25 per cent. lower in price than the former, although such difference varies considerably. Notwithstanding that the natural oil consists almost entirely of allyl-iso-sulphocyanate, the actual percentage of which it readily determined by the United States Pharmacopoeia process, the "synthetic" oil has not been included in that work.

A sample of natural oil examined had a specific gravity of 1:021 at 15°C, was optically inactive, and distilled entirely between 147° and 152°C. Three grammes yielded, when heated with ammonia in alcoholic solution, as detailed in the U.S. and German Pharmacopoeias, 3.247 grammes of thiosalmine (allyl-thio-urea), equivalent to 92.4 per cent. of allyl-iso-cyanate present in the original oil.

A sample of synthetic oil had a specific gravity of 1:020 at 15°C, was optically inactive, and distilled almost entirely at about 149°C, and indicated 92.9 per cent. of allyl-iso-sulphocyanate by the United States Pharmacopoeia thiosalmine process. The range of specific gravity of the German Pharmacopoeia, viz., from 1:015 to 1:020, is too narrow, that of the German Pharmacopoeia being 1:016 to 1:022, whilst this has been further extended in the United States Pharmacopoeia to 1:018 to 1:029 at 15°C. The German Pharmacopoeia requires that the first and last fractions of the oil on distillation shall correspond with the specific gravity of original oil, which test for the presence of alcohol, petroleum, etc., has been adopted by the United States Pharmacopoeia. This test and the others contained in that work might be advisedly adopted in a new British Pharmacopoeia.

**Lemon Oil.** — The commercial value of the two principal varieties of this oil imported into this country vary, the Palermo essence commanding a higher price by about 20 per cent. than that from Messina.

Such difference does not exist on the Continent, the Messina oil being usually employed in Germany, where its principal use is for perfumery, whilst in this country the Palermo essence is preferred for the manufacture of sirrated beverages, an industry which consumes by far the greater proportion of lemon oil in England.

The principal physical characters of the pure oils vary within the narrowest limits, and the determination of the specific gravity and optical rotation afford valuable preliminary tests for the purity of the oils.

The United States Pharmacopoeia gives as limits of specific gravity 858 to 869 at 15° C., and optical rotation not less than 60° to the right in 100 MM. tube, whilst the German Pharmacopoeia contains no definite requirements for either of these characters.

The finest oils of trade are well within these limits, but many inferior oils, the specific gravities of which are as much as 863 at 15° C, must be regarded with suspicion, and their optical rotation usually falls considerably below + 60°. It is possible, however, by a judicious mixture of turpentine and orange oils to produce an adulterant having the requisite optical rotation, viz., + 60 to + 65°, but fractionation reveals what the polariscopes are unable to disclose—the point at which the oil begins to boil being lowered by the presence of limonene, the principal constituent of turpentine, which boils under 160° C., whilst limonene, the lowest boiling constituent of the pure oil, boils at about 175° C.

An even more conclusive means for the detection of such admixture is that suggested by Schimmel and Co., which consists in a comparison of the rotations of the lower and higher boiling fractions, which should show more than a difference of 2°.

The body to which oil of lemon owes its particular aroma is an aldehyde, citral, to which considerable attention has been called both scientifically and commercially during the past year or more, but although oils have been sold in some quarters according to their citral percentage, the process by which such value has been determined has not been published, and therefore its accuracy or otherwise cannot be commented on.

The determination of the aldehyde constituents of lemon oil by an adaptation of the method employed for the determination of cinnamic aldehyde in cassia oil, viz., by shaking the oil with strong boiling solution of bisulphite of sodium, and measuring the non-aldehyde constituents, has been found to yield useful comparative results.

It was found by this process that an oil which was stated to contain 7.26 per cent. of citral, yielded 92.75 per cent. of non-aldehydes, whilst after admixture with an equal volume of oil of turpentine, the non-aldehydic constituents were raised to 98.4. It will be noted that the oils, numbered 1 and 2 respectively, whose optical rotations and fractionation figures indicate unmistakable adulteration, yield very low aldehyde percentages.

The aldehyde separated from oil of lemon was found to possess a specific gravity 8952 at 15° C., was optically inactive, and boiled between 233° and 228°.

From the above the accuracy of the tests of the U.S.P. for a pure oil is established, and it is suggested, therefore, that the tests of that work be included in the new British Pharmacopoeia with the possible addition of the requirement that not more than 30 per cent. should distil under 172° C., the rotation of such fraction not to vary more than 2° from that either of the original oil or its higher fractions.

(To be continued.)
NOTES ON ADULTERATED ACETIC ACID.

BY M. CONROY.

This sample of acetic acid came under my notice some time ago. It is the commercial kind known as 1:040, which should contain 28 per cent. of absolute acetic acid. Complaint was made by a user that it was weak, and that more had to be used than formerly. On examination the specific gravity was found to be exactly 1:040 at 60° F., but on titration with decinormal soda, the strength was found to be 24:5 instead of 29 per cent. From this it was evident that the specific gravity was a fictitious one, and that something had been added of a non-acid nature. On evaporating 100 grain measures, a solid white crust was left, weighing 1:87 grain, which was found to be sodium acetate. Thinking that this impurity might be accidental, a further supply was ordered from the same makers without comment.

This was some weeks afterwards, but on examination the same adulterant was found to about the same extent and the specific gravity exactly 1:040. These makers paid particular attention to the specific gravity, and I have not met with the same exactitude in the acid of other makers which was genuine. Now, seeing that commercial sodium acetate is dearer than 1:040 acetic acid, at first sight it appears strange why it should be used as an adulterant, but when we find that a solution in water containing 18:4 per cent. of commercial sodium acetate has a specific gravity of 1:040, we see at once how the thing is done. A solution of commercial sodium acetate of this strength would be about one-sixth the value of 1:040 acetic acid, and this sample of acetic acid contained 16 per cent. of the solution. I bring this matter forward because I have reason to believe that this sophistication is still practised and buyers are satisfied if specific gravity is correct. It will also serve as a testimonial to the ingenuity of the makers of this particular acid.

From the discussion it was evident that the unreliability of specific gravity as a test of the acid strength was well known, though it did not appear that the presence of sodium acetate had been previously noted.

NOTES FROM THE DISPENSING COUNTER UPON SOME B.P. PREPARATIONS.

BY H. O. DUTTON.

In working with the Pharmacopoeia, a point which strikes our attention is the different systems employed in writing down the recipes. In some cases we find definite quantities of all the different ingredients given, resulting in products containing nondescript quantities of active ingredients. In others we have the finished product given in quantity by weight, and in other cases the active and principal ingredients given in definite quantities, and the solvent or diluent ordered in sufficient quantity to produce so much by measure. To my mind, as a dispenser, the last system is by far the best, and might with advantage be considerably extended so as to embrace almost all the fluid preparations. If this were done, it would be the means of avoiding many little errors which have crept into the book.

Under most of the drugs and chemicals we are given their strength in the different preparations into which they enter, and these figures are often confusing and require re-calculating in almost every instance when a dispenser wishes to know the proportion in a certain measure. Tables of strength to be of practical value, I think, should be given in every case in the lowest figure, that is, 1 of the drug in so many minims or grains, or fluid ounces, and ounces. The parts and fluid grains system is not a success. The book itself proves that it is very easy to make mistakes in this matter. Take page 67; under atropine it states that the ointment is 8 grains in 1 ounce, but the recipe for that ointment orders 1 ounce of benzoated lard, 8 grains atropine, and ½ fluid drachm spirit of wine. Under sulphate of atropine it states that the liquor of that salt is 1 in 100 fluid grains, and under acetate of morphia the same strength for the liquor is given. In the former case, turning to the recipe, we have 990 minims of camphor water ordered to be used, while to make the latter only 978 minims of the three fluids are ordered, and no allowance made for the slight contraction between the spirit and water. If, as I take it, the alkaloids do not increase the bulk to anything like the extent of 10 minims or 10 fluid grains, the resulting solutions are not 1 in 100, either by weight, measure, or part.

Then, again, working from the directions for the preparation of the different recipes, in many instances they are not what we might consider models of the best method of procedure; some are unnecessarily prolix, while others leave much to the imagination. Take a class of preparations, for instance the syrupes. With the exception of three or four, these all entail the solution of sugar at the time of making, and in the directions to do so we have the following rather indefinite means ordered to effect it, viz., heat, a gentle heat, and a little heat for most of them; while for syrup of tolu steam or water-bath heat, and in the case of syrup of poppies we are not even told to dissolve the sugar at all, merely to add it to the remaining liquor, after distilling off the spirit and evaporating to two pints. To make the simple preparation glycerin of carboxylic acid we are given two processes, one of which is quite unnecessary.

Glycerin of Alum. — As both the potash and ammonia alums contain nearly half their weight of water, and the continued heating to effect solution drives the whole or part of this water away, according to the heat employed, the resulting solution is stronger than intended, and unless made up to weight with a sufficient quantity of water to allow for the loss, I have found it to be liable to crystallise out. That it may be due to this may be proved, I think, by the fact that the ammonia alum (which contains the greater proportion of water, viz., 432 in 906, against 432 in 948 in the case of the potash alum) is the more soluble in glycerin of the two salts.

Lin. camph. co. is an example of my contention in regard to inaccurate or inconsistent statements. There is no allowance made for the space occupied
by the camphor and oil of lavender, and the contraction on mixing the spirit and ammonia is not sufficient to make the liniment 54 grains of camphor in the fluid ounce, as stated under the heading of camphor. The product is about 22 fluid ounces, using B.P. quantities.

Liquors of the Chemical Salts, Acetate and Citrate of Ammonia, etc.—These diluted solutions are principally made up to a definite measure, and where impossible, as in the case of liquor calcis saccharatus, a statement of s.g. ensures accuracy. As a dispenser, using the measures at present in vogue, that is, divided into 5 minims and multiples, I think that for the diluted solution of acetate of ammonia the strength 1 in 5 is somewhat inconvenient in many dilutions. One in 4 or 1 in 6 would be much more practicable, as the concentrated solution is the best form in which to preserve it. As it is usual, I think, to dilute it down at the time of dispensing a prescription, this means taking 12 minims and multiples of 12 for every dram, instead of, as in the case of liq. ammon. citrat., 15 and multiples of 15, which are marked upon our measures and are readily and accurately gauged. I cannot see any particular reason why the two solutions should not be of the same dilution.

The present form for liq. bismuthi when first introduced gave rise to considerable discussion as to its keeping qualities. I made a sample substituting 1 dram of glycerin for 1 dram of water per fluid oz. of the solution, and found it to keep perfectly for years, but as this would hardly have been a legal substitution, another method which I have tried is to make it of double the bismuth strength, diluting when dispensing. This answers perfectly well and I get a solution colorless and almost neutral as the Pharmacopoeia orders. In passing I may state that I have found citrate of bismuth an unstable salt, becoming very acid to test paper when kept for long. Of the mixtures there is only one written in the manner usually seen upon prescriptions, viz. mist. ferris aromat., in which the peppermint water is ordered in sufficient quantity to make up to 1 pint.

In the case of mist. renna oo., the intention evidently was to produce 1 pint of mixture, as under sulphate of magnesia, the B.P. says 1 in 5. In writing down the recipe, however, the fact that the salt contains nearly half its weight of water must have been forgotten, and as a definite quantity, 15 fl. ozs., of infusion is ordered to effect solution, the product is 22$\frac{1}{2}$ fl. ozs. about, leaving the sulphate 1 in 54. As it is usual and proper I think to send this out bright, I think it might be ordered to be filtered. Syrup ferri iodidi is an unsatisfactory process for several reasons. One method I have found to work well, enabling me to send it out uncoloured and freshly prepared, which also can be applied to so small a quantity as 4 fl. ozs., is to make it upon the lines of the syrup ferri subchlor of the Appendix, combining 2 drachms iodine with 1 dram iron, in the presence of 3 or 4 drachms of water, filtering this through a small cone of paper into 3$\frac{1}{2}$ fl. ozs. of simple syrup, and washing flask and filter with sufficient water to make up to 4 fl. ozs.

Syrup. ferri phosph. is a tedious and troublesome process; it is liable, unless carefully done, to considerable loss of phosphate in washing, and to oxidation during that process, and working in large quantities takes a deal of washing to get rid of sulphate. The solution of the phosphate for syrup would be better prepared by dissolving the metal in the acid on the plan of the Extra Pharmacopoeia and B.P.O.

The hard and soft paraffins make a very satisfactory basis for ointments, much more so, in my experience, than the ung. simplicis, the latter becomes very granular after keeping, and I think that ung. hydrarg. ammoniati would be much improved if ordered to be made with these instead of with simple ointment as at present. It would be a good addition to the list of ointments if one for ung. petrolata—1 hard and 2 soft paraffin—were added. This consistency is easily worked, and for such ointments as ung. sulph. iodidi, where a softer basis is ordered, can be readily dispensed without heat by using the proportion of this containing the required quantity of hard paraffin, and diluting down with a sufficiency of soft paraffin to bring up to weight. The directions for preparing ung. chrysarobin would be improved by adopting the directions for ung. pot. sulphurata, i.e., rubbing the chrysarbin down, and adding the melted lard gradually, also a statement as to the length of time to maintain the moderate temperature might be given.

Among the tests for rectified spirit I would suggest that there might be added after “remains clear when diluted with water” the words, “and does not darken in colour on the addition of liquor of ammonia.” I have met with samples which have done so, and I find that Squire states that it is generally considered to be due to the presence of tannin. This may not be of importance in many instances, but is fatal to the appearance of tinct. quinquini ammoniata.

In conclusion, gentlemen, in these few notes I have endeavoured to make out that the directions for making, as a part of the B.P., are worthy our attention, and that in many instances they might be much improved, also that a system of making up to a definite quantity, more particularly in the case of fluids, might with advantage be extended to the mixtures, glycerins, etc., etc.

An interesting discussion followed the reading of this paper.

The President approved of the recommendation, that syr. ferri phos. should be made by direct action of the acid upon the iron, but found that a more stable preparation is made without heat. Mr. Conroy believed that the colour produced by ammonia in some rectified spirit is due to the German practice of coating the insides of casks with glue, which is partly dissolved by the spirit. Mr. T. F. Abraham hoped that in the next pharmacopoeia the one per cent. solutions would be made one grain (weight) in 100 minims. Mr. A. C. Abraham pointed out that whatever was the intention, syr. ferri phos. of the Pharmacopoeia contained both ferrous and ferric phosphate, and that a syrup prepared as Mr. Dutton approves would not have exactly the same medicinal properties.
THE SOLVENT ACTION OF PEPsin ON ALBUMIN WITHOUT HEAT.

BY J. T. HORNBLOWER.

In determining the solvent power of pepsin I usually make four or five mixtures of, water, 1 oz.; albumin, 100 grs., and acid hydrochlor., 5 min., as prescribed in the B.P., and then add pepsin in varying proportions to see the smallest quantity that will dissolve 100 grs. of albumin; not always throwing away the contents of the bottles as soon as the test was finished. I have many times noticed that a mixture containing much (perhaps 1/2 or even 1) undissolved albumin would in the course of a day or so become quite clear, showing that time, apart from temperature, was no inconsiderable factor. It then occurred to me that it might be useful to see the effect of pepsin on the albumin without heat. I accordingly made three mixtures as mentioned before, and added 2, 1, and 1/2 grains of pepsin respectively; the result was a complete solution in about 24, 48, and 72 hours, showing that the time taken for the solution was proportional to the quantity of pepsin present. Another sample of pepsin (using 2 grains) dissolved the albumin in about nine hours, though in each case the bulk was dissolved much sooner, as the solvent action on albumin is usually determined with a certain amount of heat. I thought it might interest some members to know (if the fact is not already known) that there is a not inconsiderable action without it; and, too, one might imagine there would not be much, seeing that pepsin in its normal condition acts at 99° or so. The only practical deduction I can at present see to be drawn from this is, that when testing a sample of pepsin, and more especially when judging the value of different samples simply by the solvent action on albumin, that, as the action is always going on, it is absolutely essential to make any comparisons directly the allotted time for testing has expired.

Mr. Hornblower's communication produced an excellent discussion, in the course of which Mr. A. C. Abraham suggested that Mr. Hornblower should continue his investigation with the object of producing, if possible, a process for determining the solvent power of pepsin in the cold.

Correspondence.

[Letters should be written as concisely as possible, on one side of the paper only, and preferably with name and address for publication.]

LIQUOR AURI ET ARSENII BROMIDI.

Sir,—An error has crept into the eighth edition of the 'Extra Pharmacopoeia' on page 83, which I wish to correct. The amount of Clemens' solution, about equal to 3 grains of oxonium of arsenious, should be 120 minims, instead of double that quantity—834 minims, as printed. The formula should thus read—Bromide of gold, 1/4 grain; oxonium of arsenious, 3 grains (= Clemens' solution, 192 minims); distilled water to 1 ounce. Dose, 5 to 10 minims. The preparation has been recommended by Dr. E. A. Wood, of Pittsburgh, U.S.A., for various nervous affections. The arsenical compound is given in different formulae as bromide of arsenious and oxonium of arsenious. The former is insoluble without decomposition, and the latter is indefinite; two formulae are given for it in Watts' 'Dictionary.' Solutions of either oxonium are generally found to be incompatible with the tribromide of gold, producing a colourless liquid with reduction to metallic gold. I have found by using Clemens' solution, which contains a definite quantity of metallic arsenum with some bromine in combination, an equivalent to the solution of two metallic salts can be prepared stable. The 'National Formulary, U.S.,' has, I notice, altered the proportion of arsenic contained in Clemens' solution. This there contains about 1 per cent. of arsenical acid; the formula generally adopted in England makes it about 1 in 20. May I ask your readers who have bought early copies of the 'Extra Pharmacopoeia' to make the above correction?

W. MARTINDALE.

New Cavendish Street, W.

EARLY HISTORY OF PHOSPHORUS.

Sir,—In my possession is a curious old work on chemistry, published by Nicholas Lemery, M.D., in 1686. He refers to the "hermetic phosphorus of Baldinhus" as a mixture of chalk and the acid spirits of aqua fortis, which makes it lucid. Strange he does not mention Brandt, but says, "Kunkelius, a Saxon, has written very well upon it and worked to good effect." "Daniel Kraff, a German, the inventor of phosphorus from urine; he gives it the consistence of a paste or liquor, as he pleased." Again, "The Honorable Mr. Boyle, of London, to whom all the ingenious have so much obligation, put forth a treatise in English three or four years ago, called 'Nocti- luca Aeria,' full of an abundance of experiments and most curious remarks which he has found upon this phosphorus." He speaks of the "Bolonian stone" being one of the first artificial phosphors known, but that the author, who lived in a town of the same name in Italy, was dead and left no knowledge of his secret. From his description of it, it would seem to be a sulphide, probably of barium or some such substance.

30, Trinity Street, S.E.

H. SKINNER.

THE ATOMIC THEORY.

Sir,—The two letters and foot-note in the Journal of last week convey all the information I desire, or can expect. I have fallen on evil and scientific days and am behind the age. Alas! in the rosy morning, when the laws of chemistry were imparted to me, Dalton's theory—beautiful in its simplicity, was explained in my 'Attfield' as an expedient to reason from (the relative weights of elements being absolute), and the brick-and-mortar building-up of molecules was carefully discriminated against. I prefer the old way, and will remain for the present content with my ignorance and unbelief; that is flat. Moreover, though not claiming to be wise or learned, or seeking to screen myself under theegis of philosophy, a hard and cruel logic plays the policemen with me, in a constant 'Move on there; you can't stop here!' So, as I lack the power of imagination and, the only expedient I can think of is to dissolve the atom and get through it that way. I will doubtless gravitate to atoms some time, but meanwhile I do not look upon them as true girt. My obligations to both gentlemen.

Glasgow.

ALEX. LAING.
Notes and News.

STAMP COLLECTING AND DISEASE.—According to the British Medical Journal, it is desirable that stamp collectors should guard against the possibility of importing the germs of various incontrollable diseases from their native haunts abroad. Dr. Unna has recently had under his care a case of "piedra," a disease of the hair peculiar to Columbia, South America, in which black gritty particles, consisting of the closely-packed spores of a special fungus, form on the hair shafts, and give off an objectionable acid smell. The patient had never been near Columbia, but often received letters from there, and was in the habit of detaching the stamps by soaking them in water. Probably, therefore, he communicated the disease to his beard by means of his wet fingers.

LONDON CATALOGUE OF BRITISH PLANTS.—The ninth edition of this useful book has just been published by George Bell and Sons, London, for Mr. F. J. Hanbury, and now deals with 1958 species, in addition to a large number of varieties. A detailed notice of the work will appear in the Journal later.

ROYAL PHOTOGRAPHIC SOCIETY.—This Society has instituted a series of "photo-mechanical" meetings on Tuesday evenings. Persons interested from a trade point of view or otherwise are invited as well as members.

INSURANCE AGAINST ACCIDENTS IN THE PHARMACY.—Some time ago in a French pharmacy, salt of sorrel was inadvertently supplied to a customer instead of iodine salt. As a result, the person taking it died, and the proprietor of the pharmacy was condemned to pay 500 francs as compensation, in addition to an annuity of 150 francs to each of the four orphans of the deceased, until they attain their majority. The pharmacists, however, was assured in the Société mutuelle d'assurance contre les accidents en pharmacie, and in consequence the penalty has been paid for him, and he has reimbursed all the expenses he had incurred. The Society is said to be in a prosperous condition, some two hundred persons being insured, and it is gradually, though slowly, increasing in numbers.

EXPLOSION OF CARBON DIOXIDE CYLINDERS.—The Scientific American reproduces some photographs taken by a pharmacist of Lebanon, Pa., after a fire at a bottling works in that town, accompanied by the explosion of some carbonating cylinders. The first cylinder that exploded in consequence of the heat had the bottom blown out. It then passed through the side of the building and across the street into a double frame dwelling house, where it did great damage before emerging in the yard behind. Another cylinder was turned completely inside out, and blown a short distance outside the building, whilst a third one was recovered uninjured.

PUBLIC ANALYSTS IN AUSTRALIA.—The Australasian Journal of Pharmacy announces that the Board of Public Health has consented to recognise as eligible for the post of analyst under the Colonial Health Act all persons who have passed the final examination of the Melbourne College of Pharmacy, and have undertaken for a further period of twelve months at the College certain courses of practical instruction, and been awarded certificates of proficiency in the subjects, including simple and complex qualitative and quantitative analysis, including qualitative and quantitative analysis of water, beverages, and foods.

THE SUMMER HOMES OF THE SEA-BIRDS.—An interesting article on this subject has been contributed to Nature Notes for April by Mr. W. J. C. Miller, Registrar of the General Medical Council.

ROYAL GARDENS, Kew.—The second part of the useful official guide to the museums of economic botany at Kew has now been published, and deals with the monocotyledons and cryptogams. It is sold at the Gardens at an exceedingly modest price (4d.), and will be found of great assistance to visitors who take an intelligent interest in the exhibits.

ORIGIN OF THE WORD "ARSenic."—A correspondent of the Academy, dealing with this subject at considerable length, sums up, by assuming that the Greeks, as early as the fifth century B.C., borrowed, perhaps from the Persian, a word to which they gave the form of *σκαρπανίς* and applied it to the red sulphuret of arsenic or realgar. Six centuries later, "Dioscorides—wishing, perhaps, to find another word for the yellow sulphuret of arsenic or orpiment (which had, possibly, up to that time been included in the term *σκαρπανίς*), and finding in some other language, perhaps Arabic, a word with this meaning, viz. *sarnik* (or *acarnik*), in which he discovered some resemblance to *σπαρνάς* = "male" (as a form of *σπάρω*)—boldly adopted this latter word, and gave it a new meaning." It is pointed out that the curious part of the matter is that, if this view is correct, *σκαρπανίς* and *σπαρνάς* both would appear to have been taken from the same Oriental word, modified somewhat, perhaps, both in form and in signification in the course of centuries, and in its passage from one Eastern language to another.

MICHIGAN STATE PHARMACEUTICAL ASSOCIATION.—The record of the proceedings of this Association at its last annual meeting, held at Detroit, Michigan, forms a handsome quarto volume of over 100 pages, which is illustrated by numerous portraits of past and present officers.

CHEMISTS’ CO-OPERATIVE SOCIETY.—What the Financial Times refers to as "another case of wholesale centralisation," the formation of a limited liability company to purchase and run nearly eighty retail pharmacies (see p. 988), is not favourably viewed by the daily press generally, one paper remarking that there is something about the company "which is not altogether attractive," and concluding with the statement that "one cannot avoid the feeling that the venture is one which cannot be recommended as an investment that is likely to prove satisfactory."
Miscellaneous News.

[Readers are invited to send local information of pharmaceutical interest. When newspapers are sent the paragraphs to be noted should be plainly marked, whilst cuttings should be verified by the addition of source and date.]

WEIGHTS AND MEASURES ACT.—At a meeting, held on Tuesday last, of the Select Committee of the House of Commons (Sir H. Roscoe, Chairman) in reference to the application of the Weights and Measures Act to the trading in substances used in medicine, Mr. Charles Unny, of the firm of Weight, Laycock, Unny, wholesale druggists and manufacturing chemists, of Southwark, London, gave evidence. Referring to drugs of vegetable and chemical origin, he stated that, so far as vegetable drugs were concerned, the port of London was the market of the world almost for such imports. Most of the drugs that reached London passed into the hands of the East and West India or other dock company, and were weighed or measured by imperial weights and measures only. Notwithstanding that these drugs were disposed of at public auction and to buyers who largely represented countries in which the metric system was in vogue, still, as far as he had learned, no objection had ever been raised to the use of imperial weights and measures in such weighing or in rendering account sales, and, in his opinion, as British trade was at no disadvantage by the continuation of these weights and measures, it was unadvisable to discontinue their use.

Drugs of chemical origin were produced in England to some considerable extent (many of such being also used in the arts) but the great variety of medicinal substances were produced on the Continent of Europe, and notably in Germany. If a manufacturing chemist in England required the prompt despatch of chemicals from Germany he was generally supplied with such from stock, and in all probability weighed by metric weights; on the contrary, if he gave instructions that his chemicals should be specially weighed by imperial weights, such instructions would be as easily followed, and the authorities in Germany would offer no objection to the use of British weights. In selling drugs in England avoirdupois weight was used, in dispensing medicines troy weight was used, but in exporting medicines to some ports of the world, notably Spanish South America, it was often customary to have the drugs sampled and the quantity specified in troy weights and measures only. As far as he (Mr. Unny) understood the present Weights and Measures Act, metric weights could only be kept in a laboratory for scientific purposes, or in a warehouse for checking the accuracy of the weight of goods imported, and so soon as the metric weights were used for weighing goods passing outwards, the use of such weights was illegal. This, he thought, was most objectionable, and a great hindrance to export trade. As hon. sec. of a club representing the leading wholesale druggists of England, he had in his hand letters showing that his confreres, both in London and Liverpool, view the working of the present Weights and Measures Act, if strictly enforced, as a great impediment in the conduct of their export business.

As a member of a committee recently appointed by the Pharmaceutical Society of Great Britain to aid the General Medical Council in the production of an Improved Pharmacopoeia, Mr. Unny also stated that, in his opinion, if a revised Pharmacopoeia was to be possessed of that intercolonial and international character that ought to be an essential of such a work, the metric system of weights and measures was an absolute necessity in its issue, and in adopting such a system for setting out the formulae by which medicinal substances were to be compounded they would only be following every European nation (including Russia) and also the United States of America, Japan, etc. Mr. Unny further pointed out that a pharmacist of any nationality could with a prescription before him in metric weights and measures decipher it not only with mental ease, but with greater safety to the public than if the weights and measures of the prescription were indicated by the British system. He thought the objection to the use of weights and measures for general trade purposes (other than medicines) must necessarily be gradual, but that with the better education of the rising generation in the simplicity and advantages of the system a more speedy adoption would come about.

CHEMISTS CO-OPERATIVE SOCIETY.—The Financial Times refers to another case of wholesale centralisation which is now before the public. The Chemists' Co-operative Society, Limited, proposes to take over no less than seventy-six selected businesses of chemists and druggists and to run them from one centre on the co-operative principle by means of a contract under which it is to acquire immediately forty businesses as going concerns. Of the seventy-six concerns, twenty-five will be in London, and fifty-one in the provinces; "so that the enterprise," remarks our contemporary, "will certainly be spread wide enough to come in for extensive patronage from the public if well managed. Besides, it is proposed to gradually acquire other shops as opportunity offers, and to open various fresh establishments and a laboratory and warehouse." It would seem that the Financial Times young man has had at one time or another to pay more than he thought enough for his humble snuff powder or ounce of salts, for he continues in a pathetic vein: "If the Chemists' Co-operative Society enables the public to get good drugs and medicines below the present exorbitant charges, it will not have lived in vain."

CO-OPERATIVE CHEMISTS.—There is something about the Chemists' Co-operative Society, Limited, which is not altogether attractive. The buying up of a larger number of retail establishments with the idea that they can be worked very cheaply under one management and thereby be made to yield a handsome profit on very big purchase prices, is an old one. It has often been attempted, and failed, but has not died nor has the idea of the Chemists' Co-operative Society. We can confess that at the moment we cannot call to mind a single instance in which it has. The notorious Bread Union was a device of the kind, and we knew what came of it. The profit estimates in this Chemists' Company are very loose and unsatisfactory. A number of establishments are to be purchased which have been making for their proprietors an average profit of £300 a year each. Are they likely to be worked by a manager for much less in the future? If not, where will the profit come from? The accountant's certificate says that it was not the practice at these shops to take stock! Consequently, the profit estimates must be largely one of estimate. Altogether one cannot avoid the feeling that the venture is one which cannot be recommended as an investment that is likely to prove satisfactory.——Sun.

THE CHEMISTS CO-OPERATIVE SOCIETY, LIMITED.—With a capital of £200,000 this company has been formed to centralise the retail drug trade in England, importing, manufacturing, and exporting drugs and druggists. The capital is £200,000, divided into £100,000 Seven Per Cent. Cumulative Preference shares of £1 each and £100,000 ordinary shares of £1 each. For the life of me I cannot see what inducement is held out to investors to place their money into a concern like
this. From the prospectus it appears that the company will immediately acquire forty establishments of chemists and druggists, all going concerns. Well may I be said the businesses are going—at a good price—to good that I should advise my readers to wait for something else.—Truth.

AN ALLEGED BOGUS DRUG COMPANY.—At the Exeter Bankruptcy Court on Saturday, April 27, before the Official Receiver (Mr. T. Andrew), the first meeting of the creditors of William Dale Bayliss, of 69, Union Street, Torquay, chemist and druggist, trading under the style, firm, or company of the "Bayliss Drug Company, Limited," was held. A declarator whose statement of affairs showed assets amounting to £2171 10s. 10d., liabilities, £2947 16s. 3d., and deficiency £729 17s. 5d., attributed his failure to overstocking and pressure by creditors, and further says: "On February 26, 27, and 28 last the Sheriff held a sale of a portion of the stock-in-trade at the suit of Sanger and Sons for a debt of £192 and costs. The sale realised £424, leaving the Sheriff £240 or thereabout. This sum is still in the hands of the Sheriff, but as an issue is now before the court, I do not carry same out as an asset, neither do I schedule Sanger and Sons’ debt as a liability." The Official Receiver’s observations were as follows: In December, 1893, the Bayliss Drug Company, Limited, was formed, consisting of the debtor and six other members of his family. In February, 1895, Messrs. Sanger and Sons obtained judgment against this company, and the Sheriff levied and sold for £192 and costs. A provisional order under the Companies Act was made, but not in time to dispose of the Sheriff, whereupon certain creditors filed a petition in bankruptcy against Bayliss individually, alleging that the Bayliss Drug Company was a bogus affair, although duly registered. An interim receiving order was made, and the Official Receiver claimed the proceeds of the sale in the hands of the Sheriff. The Sheriff thereupon interpled, and the Master directed an issue to be tried by jury, the question being whether these proceeds belonged to the Bayliss Drug Company or to the debtor Bayliss personally. The County Court judge held that the company was bona fide, and for the benefit of its creditors only, and made a receiving order accordingly. But what the result of this action may be it is impossible to say, and more especially because the question raised is unique. The sum which the debitor says he invested in this business was £500 in cash and three bills of exchange for £100 each. The books of account purported to be the books of the company." The usual order was made.

ROYAL SOCIETY SOIREE.—The first soiree of the Royal Society was held at Burlington House on May 1, a month earlier than usual, and the exhibits were as numerous and interesting as on any previous occasions. There was an electrical furnace, used for the melting of such obstinate metals as chromium, titanium, and platinum, some of which require a heat of from 2500 to 3000 degrees centigrade. Professor Roberts-Austen explained that the furnace consisted of a fire-clay case lined with magnesia, and contained a magnesia crucible. Messrs. Johnson, Matthey, and Co. exhibited specimens of the six metals which compose the platinum group:--nuggets of 165 ozs. and a palladium ingot of 1000 ozs. the latter being the only one of any size produced. There were also a rhodium ingot, osmium melted and sponge, ruthenium melted by the electric arc, and a pure iridium rolled sheet. Professor Ramsay showed spectra of argon extracted from air, and a mixture of argon and helium extracted from clevette. Mr. Norman Lockyer showed a photographic spectrum of Orion, taken with a six-inch telescope, and enlarged twelve times. Mr. W. N. Stillman showed by means of glass globes and an apparatus which produced a mixture of two currents of air at different temperatures, how clouds could be formed with a whirling movement analogous to a cyclone. In another globe the formation of cloud of the quiet fog type was effected by a sudden expansion of air, causing depression of temperature equivalent to an elevation of 10,000 feet. A mechanical device for correcting temperature was shown by Dr. John Shields, and Dr. J. Norman Collie introduced a new and simple form of barometer, in which a minimum of mercury is used. It can be stored away in a drawer on its side or upside down without risk, is extremely accurate, and does not easily get out of order. Sir B.W. Richardson’s electrical cabinet embodies a light with reflector for illuminating the throat, an electric cautery, etc., etc. It can be moved from bed to bed as required, and the current may be supplied from a small battery in the shade. The latest form of his “potentiometer” and simple forms of platinum thermometers for use with it. Professors W. M. Hicks and J.A. Fleming also exhibited instruments, Dr. Hopkins a large electro-magnet, Professor Swig a magnetic tester, Major Holden, R.A., an optical electric meter, and Major Carr, R.E., specimens of the deposit or incrustation on the insulators of the electric light mains at St. Pancras, in which metallo sodium and potassium were found.

In natural history a number of interesting objects were exhibited. Some spotted potato slices in glass cases, arranged by Mr. W.T. Burgess, impressed visitors with the constant risks to which they are exposed by flies carrying infection. House-flies were shown walking over slices of sterilised potatoes, and in other cases the disagreeable results of their wanderings were represented by colonies of crimson flies. Professor V. B. Lewes exhibited aesthetes for illuminating purposes; Dr. Gustav Mann, microscopic specimens of nerve cells; and Mr. R.E. Crompton, apparatus showing the application of electricity to trade and domestic purposes. On the ground floor, also Lord Armstrong illustrated the results of recent experiments on the electricity, discharge, the demonstrations being made by means of a powerful electric lantern and a number of beautiful slides.

INFLUENCES OF TRADES ON FACES.—A curious paper, remarks the Daily Telegraph, is contributed to the new number of "Blackwood’s," by Dr. Louis Robinson on the influence of trades on faces. It is pretty generally agreed that association with horses gives a person a horse yard look; but it appears that circus riders and ring-masters are exempt from the general rule, because with them the horses are regarded as more "properties," and their minds are occupied solely with the achievement of certain feats to the satisfaction of the public. Dr. Robinson takes as types professional musicians, priests, actors, actresses, blacksmiths, and about 150 others, and purports to induce strongly-marked facial expression. Even the style of hair which has become associated with musicians is not altogether dependent on fashion, but is evidence of trophic changes resulting from mental habits. The growth and vitality of the hair are profoundly influenced by emotions. Illness cannot change the hair of the race without the wishes of those who believe in the powers of the will. For some mysterious reason the subcutaneous tissue over the cheekbones and under the jaws of the cleric’s face gets an undue supply of nourishment, which leaves distinctive marks, while
Poisoning Cases and Inquests.

**Poisoning Cases and Inquests.**

**Sulphuric Acid.**—George Cole, aged 64, died on Wednesday, April 17, in the Southern Hospital, Liverpool, from the effects of sulphuric acid, self-administered. Verdict: "Suicide whilst temporarily insane."

**Laudanum.**—James Shepherd, aged 67, died on Sunday, April 21, at 6, Derby Row, Newton-le-Willocks, from the effects of laudanum, self-administered. Verdict: "Suicide whilst temporarily insane."

**Mercury.**—Joseph Williams, aged 57, died on Thursday, April 18, at Herbert Cottage, Lilianwarne, from the effects of mercury, self-administered. Verdict: "Suicide whilst of unsound mind."

**Laudanum.**—David Bryon Cole, aged 25, died on Tuesday, April 23, at Charlotte Street, Fitzroy Square, London, from the effects of laudanum, self-administered. Verdict: "Suicide whilst of unsound mind."

**Strychnine.**—At the inquest held on the body of Robert Pollitt Rawsthorne (see ante, p. 957), on Friday, April 19, Dr. G. Patrick said he had made a post-mortem examination of the body, and had found there were all the symptoms of strychnine poisoning. The coroner observed that the sooner the law with regard to the sale of poisons was altered the better, and said he had often had to complain of the many facilities open for getting poison, as if a man was wishful of putting himself out of the way he could easily do it. Verdict: "Death due to strychnine poisoning, the deceased suffering from temporary insanity at the time."

**Laudanum.**—Catherine Sinclair or Sim, aged 40, died on Tuesday, April 23, at 61, Dale Street, Glasgow, from the effects of laudanum, self-administered.

**Oxalic Acid.**—A lance-corporal in the 2nd Scots Guards, named Macdonald, died on Thursday, April 25, at the Chelsea Barracks from the effects of oxalic acid, self-administered.

**Prussic Acid.**—William Hudson, aged 56, died on Wednesday, April 24, at 184, George Street, Glasgow, from the effects of prussic acid, self-administered.

**Laudanum.**—Ellen Price, aged 30, died on Wednesday, April 24, at Northenden, from the effects of laudanum, self-administered. Verdict: "Suicide whilst in a state of unsound mind."

**Oxalic Acid.**—Frank Sanders, aged 26, died on Friday, April 26, at 26, New Street, Exmouth, from the effects of oxalic acid.

**Carbolic Acid.**—William Webb, aged 47, died on London Fields on Thursday, April 25, from the effects of carbolic acid, self-administered. Verdict: "Suicide whilst of unsound mind."

**Laudanum.**—William George Chandler, aged 41, died on Sunday, April 28, at Whetstone, near Leicester, from the effects of laudanum, self-administered. Verdict: "Suicide during temporary insanity."

**Sulphuric Acid.**—Annie Mayle Cottral, aged 2 years, died at Doncaster, from the effects of sulphuric acid. At the inquest held on Tuesday, April 30, a verdict of "Accidentally poisoned" was returned.

PATENT OFFICE BUSINESS.

APPLICATIONS FOR PATENTS.

No. 7638.—Pneumatic tube for rupture belt. April 17, 1868.

No. 7696.—Improvements in and connected with the sterilisation and preservation of milk, cream, and other fluids. April 17, 1868.

No. 7706.—Improvements in the treatment of cod-liver oil. April 17, 1868.

No. 7710.—Preserving perishable articles. April 17, 1868.

No. 7741.—Improvements in closing devices for bottles. April 18, 1868.

No. 7777.—A new or improved nasal respirator or inhaler. April 18, 1868.

No. 7780.—Improvements in or appertaining to devices for drawing corks, compressible stoppers, or the like. April 18, 1868.

No. 7837.—An improved apparatus for electrically heating liquids. April 19, 1868.

PATENTS PUBLISHED APRIL 20.

Vanillin (Abel, C. D., communicated from Haarnann and Reimer).—The inventors slowly add iso-eugenol to a cold solution of sodium peroxide, and warm the mixture until the “iso-eugenol-sodium” at first separation has dissolved, and the action by which the iso-eugenol is oxidised to vanillin has finished. From the solution the vanillin is separated and purified as usual. The oxidation might be effected by means of peroxide of hydrogen, manganese dioxide, or by other means. The iso-eugenol may be prepared by heating eugenol with a strong solution of an alkaline hydrate, as described in the specification No. 17,547 (1890) of De Laire. No. 11,663 of 1894.

Trusses (Straus, A.).—Relates to trusses for emphalus or umbilical hernia or other ruptures, and consists in using a pad which fits within the “guts” of the rupture, but is not actually attached to the belt which secures it in place. For this purpose the pad is carried by an indiarubber bag, other disc backed with a woollen fabric, and bearing on, but not attached to, a smooth plate forming the front of the belt. The latter thus holds the pad in position, but adjusts itself to the movements of the body. No. 12,089 of 1894.

Milk product (Wetter, J., communicated from Hentschel, L.).—Comprises the production from cream, of a semi-solid food containing all the fat, albumen, casein, and sugar of the cream. In preparing it cream is beaten up into a froth and heated by a current of dry air until sufficient dry froth is formed to be turned into moulds. The product has the taste and odor of milk, shows no fatty globules under the microscope, is capable of forming a milky emulsion with water, and does not melt at the temperature of boiling water. No. 146 of 1895.

Dental Clamps (Richter, R.).—Relates to the securing of the wads which are employed for keeping teeth dry during the operation of filling, and consists in fitting the clamps now in use, with platinum or other wire bows or hooks, and bent, pointed wire shanks which pierce and hold the wads. No. 2145 of 1895.

Tooth brushes (Thompson, W. P., communicated from Brock, J.).—The portion carrying the bristles is arranged crossways at one end of the handle to permit of readily cleansing the teeth both vertically and horizontally, and a small "round arch" is formed in the handle for cleansing the backs of the teeth. No. 4665 of 1895.

BITTER ALMOND OIL oxidises, with formation of benzoic acid, unless it be kept in full bottles or have 10 per cent. of alcohol added to it, according to Schimmel and Co.

HOUSEHOLD OR CLOUDY AMMONIA is made by dissolving ammonium olate in liquid ammonia. The process is patented and the name is copyright.

* From the Illustrated Official Journal (Patents).

Technical Notes.

SOLUBILITY OF SULPHATES OF LEAD. — Messrs. Gladstone and Hibbert found that sulphate of lead is also readily soluble in dilute sulphuric acid, and insoluble in dilute acid mixed with sodium sulphate. This conclusion is confirmed by the following note of an experiment by Mr. P. W. Burman:— "Dissolved a small quantity of lime in a warm, strong solution of caustic soda, which was allowed to cool and then filtered. This filtration is made neutral with dilute sulphuric acid, phenol-phthalein being used as the indicator. This solution, together with the precipitated lead sulphate, was divided into two portions, which were set aside for the precipitate to partly settle. One portion was repeatedly filtered, a portion of the filtrate being each time tested with $\text{SH}_2$, when on each occasion it gave a distinct brown coloration. The other portion was acidified with sulphuric acid till it contained about 10 per cent. of free acid, and was then subjected to the same treatment of filtration and testing with $\text{SH}_2$, with the result that the brown coloration was even more marked than before, and was constant in depth after each filtration. It is known that sulphate of lead is not absolutely insoluble, even in pure water.—Electrical Review.

FERROCyanide of Potassium as an Oxidant.—Experiments are being made with a view to utilise this oxidant in electro-chemistry. It is not at first sight obvious how this substance, which contains no oxygen, can act as a powerful oxidant; nor is the matter made quite clear when it is pointed out that free alkali must be present to render its oxidising power available. The explanation is that ferrocyanide of potassium has a great tendency to become ferrocyanide by appropriating additional atoms of the alkaline metal contained in caustic potash, water and free oxygen being liberated.—Electrical Review.

SACCHARIN IN BEER.—Saccharin gives a distinct fluorescence when solutions containing it are treated with sulphuric acid in the presence of resorcin, and this reaction serves as an excellent test for the substance. It is found by Gaultier, however (Zeit. für anal. Chem.), that a similar result is obtained with the resin of hops, so that for the detection of saccharin in beer, it is necessary to evaporate the liquid to a syrupy consistence, acidulate with a few drops of hydrochloric acid, and add alcohol of 94° to 96° to precipitate dextrine, then decant the alcoholic solution, evaporate again to a syrupy consistence, and agitate with ether. The ethereal extract obtained on evaporation, which contains the resin of hops and any saccharin present, is treated with boiling water which dissolves the latter only, and the resulting solution on evaporation is then easily detected by its characteristic sweetness.

NOVEL ANTISEPTIC.—Several of our most powerful and popular antiseptics, e.g., carbolic acid and nitrate of silver, lose part of their effect when admixed with substances containing albumins, because they coagulate the albumin and are precipitated with them. The result is that we have to apply an excess of the antiseptic, which means waste, and which may be objectionable in so far as such more concentrated solutions may prove corrosive or toxic. Under these circumstances a discovery made by the Chemische Fabrik an Alkali, late E. Schering, Berlin, has a wider interest. There are certain organic bases, in themselves poisonous to the lower organisms, which, when combined with these antiseptics, prevent coagulation of the albumin, and, moreover, render the agent more effective. These bases, ethylene-diamine and its derivatives, contain compounds...
Photographic Notes.

Colouring Photographs. — Hector Kraus thus describes a process recently patented in Germany. The pictures are coloured from the back. The colouring permits the finest details, in regard to light and shade, while the brilliancy of the colours and the effects produced perfectly harmonise with the general tone of the picture. Grains or other foreign bodies, for this purpose are aniline colours, which are dissolved in water or alcohol, and the solution, which can be made either warm or cold, must be as concentrated as possible. Numerous experiments have shown that certain aniline colours, dissolved in water or pure alcohol, give the desired results, while other colours require a solution, in a mixture of alcohol and acetic acid, in order to be utilised for this purpose. The number of aniline colours which can be produced in this manner is, of course, unlimited. Those colours dissolved in alcohol, or in a mixture of alcohol more or less acid, must be kept in well-stoppered bottles, so that they keep as long as possible the capacity of penetrating into the paper or other material. In order to use the prepared colours they must be diluted with a medium, consisting of pure alcohol, or alcohol mixed with acetic acid. This medium makes it possible for the artist to weaken the different colours more or less, and thus to produce darker or lighter tints, besides, it increases the penetrating capacity of the colours. The photographs, no matter on what paper or by what process they are made, are coloured before they are mounted, without undergoing any previous preparations. It is only necessary that the print be placed flat, without seams or other defects. The print is placed on a retouching frame, or a similar apparatus, on which it can be seen by transmitted light, then the colours are applied with the brush, on the back of the print, and diluted with a certain quantity of the medium. It is only necessary to keep exactly the contours, or different outlines of the pictures. The colours possess an extraordinary penetrating capacity, and enter at once into the paper, for which they possess a great affinity. It is, therefore, very easy to control the progress of the work, and to apply the colours within the limits within which they are necessary. The liquids which have served for the preparing of the colours evaporate very quickly, and only the colouring matter itself remains in the paper. By turning over the print it can be observed how the colours appear on the front, and it is possible to accurately judge the effect produced by the colours, and, if necessary, to subtract it by applying those or further tints. After the picture is coloured to satisfaction it can be mounted and burnedished like any other photograph; small high lights and finishing touches, such as jewellery or other small details, can afterwards be applied with ordinary body colours on the front side of the picture. — Photographisches Archiv, through Photography.
OIL OF PEPPERMINT IN THE TREATMENT OF PHTHISIS.—Carasso recommends the use of oil of peppermint in pulmonary tuberculosis, both by means of inhalations and by internal administration of the oil combined with creosote. He states that thirty-seven cures were effected in forty-four cases. The regimen consists in the persistent inhalation, day and night, of the vapour of the oil by means of a respirator composed of a fold of lint, which is moistened every three or four hours with 4 or 5 drops of peppermint oil. During the day a tablespoonful of the following mixture is taken every three hours:—Pure beech-wood creosote, 8 parts; rectified spirit, 500 parts; glycerin, 250 parts; chloroform, 20 parts; oil of peppermint, 8 parts. Shake before use (11 Faro Med., after Revue de Thérapeutique).

CITRIC ACID IN URETHRITIS.—Dr. Perlesse employs injections of citric acid in one per cent. solution, and also washes the urethra with a more dilute solution of 8 parts in a 1000 or 1500 parts of water by injecting 1500 grammes directly into the bladder. The former method of urethral injection is repeated six times daily, and the cure is completed about the tenth day. The method of washing is practiced once daily and the cure takes place in four or five days (Rev. Internat. de Méd., et de Thérap., February 1).

ZINC IN CHOREA.—Morian orders zinc oxide in the form of pills combined thus:—Oxide of zinc, 1 gramme; extract of belladonna, 20 centigrammes; salt of moria, 2 grammes; asafoetida and extract of valerian of each 4 grammes. Mass and divide into sixty pills. From two to four to be taken in course of the day. Valerianate of zinc he gives thus:—Valerianate of zinc, extract of hyoscyamus, subnitrate of bismuth, of each 5 grammes. Mass and divide into thirty pills, of which from three to six are to be taken daily (Rev. Inter. de Méd. et de Chir. Prat., April 10, 1895).

Trade Marks Applied For.*

No. 185,976.—CHEMICAL SUBSTANCES used in manufactur—photography, or philosophical research, and anti—caries, for the purpose of reducing, neutralizing, or disabling, or to prevent dental disease, including any goods of a like kind to caustic soda.—Colthurst and Harding, 11, Queen Victoria Street, London, March 5, 1895. Words: "Stormy petrel," and device of same.

* Compiled from the Trade Marks Journal.

Notes and Queries.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally.]

MARKING INK.

[846.] An extract from cashew nuts (cardol) is used to prepare a marking ink that does not require heating, and others are made with aniline blacks. There are many varieties of these, soluble in water and spirit respectively, and lack of success in their employment is frequently due to the use of improper material. Water-soluble "groggin" is a very good black for the purpose, and a formula given in the "Era Formulary" is as follows:—Aniline black, 60 gr., strong hydrochloric acid, 60 m., alcohol, 6 dr. Dissolve and add hot solution of gum, 1/4 dr., in water, 3 oz. Cardol for marking ink is extracted by treating the fruits with a mixture of ether, 3 parts, and methylated spirit, 1 part, allowing the greater part of the solvent to evaporate, or distilling it off, and treating the residue with an alkaline liquid, preferably lime water. The preparation is next reduced to the consistence of an ink, and is then ready for use. The following in sixty parts:—

ACID-PROOF CEMENT.

[847.] A cement, which is said to form a satisfactory coating to vessels intended to contain strong sulphuric or nitric acid, can be prepared, according to a French technical journal, by mixing powdered asbestos, 2 parts, with barium sulphate, 1 part, and sodium silicate (50° B.), 2 parts. For weaker acids silicate of 130° B. may be employed, whilst a mixture of asbestos, 1 part, sand, 1 part, and sodium silicate, 2 parts, is said to be preferable for warm nitric acid.

[848.] Formic aldehyde solution (30 p.c.), added to gelatin solution (5 p.c.) in the proportion of 0·25 C.C. to 50 C.C., converts the gelatin into an insoluble and infusible jelly. With a smaller proportion of the formic aldehyde solution (0·05 to 0·225 C.C.) the jelly remains fusible, though it is more tenacious and resistant, and on drying is insoluble in warm water; with proportions varying from 0·01 C.C. downwards, the jelly, whilst very tenacious, is both fusible and soluble in warm water. An English patent (No. 4966, of 1894), has been taken out by E. Schering, of Berlin, for the addition of formic aldehyde during the manufacture of sise and gins, and for other purposes.

ARSENIC IN DENTISTRY.

[849.] The following formula for an arsenical application is found by Dr. Johnson (Dental Review) to give successful results whenever used:—Mix arsenious acid, 20 parts, with cocaine hydrochloride, 25 parts, and sufficient lanolin to make a paste.

Porous Water.

[850.] A photographic varnish may be prepared from gelatin by soaking strips of the latter in chromo alum solution (10 p.c.) for three or four days, then washing well and dissolving by the aid of a gentle heat in an equal weight of strong acetic acid diluted with twice its weight of water. On applying this varnish the film formed on drying is insoluble in boiling water.
Obituary.

On April 21, Charles H. Lockwood, Chemist and Druggist, Ossett. (Aged 46.)

On April 28, Professor Thiern, the eminent German surgeon, died at Leipzig, at the age of 73. He was born at Munich in 1822, and after studying in his native town lived successfully in Berlin, Vienna, and Paris. After being Demonstrator of Pathological Anatomy at Munich for some time, he was appointed Professor of Surgery at Erlangen in 1854, and proceeded to Leipzig in 1867. During the Franco-Prussian war he was attached as Senior Surgeon to the 12th Army Corps. He had written numerous standard works on cholera, embryology, and other medical subjects.

On April 24 Professor Karl Ludwig died at Leipzig. As the Standard remarks, by the death of Professor Ludwig, Germany has lost one of her most eminent naturalists and physiologists. There is (says our Berlin correspondent) hardly any province of physiology in which he did not make important discoveries. To Helmholtz, D. Bois-Reymond, Bricke, and to him belongs the honour of having banished the doctrine of vitalism from German science. Some of his investigations were of vital importance to medical and natural science. His discoveries regarding the circulation of the blood and the fluctuations of pressure in the vascular system, resorption and the beginnings of the lymphatic vessels, the exchange of gases and the determination of the expansion of the gasses of the blood, and assimilation in muscles in action and at rest, are among the finest achievements of modern physiology. By the invention of the "Kymographon" he created the graphic method, which is used not only in physiological research, but also in hospitals. He was born on December 29, 1816, at Wittenhausen, in Hesse, studied at Marburg and Erlangen, and established himself as a private lecturer at Marburg in 1842. In 1846 he was appointed Extraordinary Professor of Comparative Anatomy there, and in 1849 ordinary Professor of Anatomy and Physiology at Zurich. From there he was called, in 1855, to the Josephinum (the former training academy for Army surgeons), in Vienna, as Professor of Physiology, and in 1865 to the University of Leipzig. There he remained as a teacher and investigator for thirty years, with rare acceptance and success, and the number of his hearers was uncommonly great. The physiological Institute of the Leipzig University, built under his direction, was the first of its kind, and has served as a model for many others. His principal work is his 'Compendium of Human Physiology' ('Lehrbuch der Physiologie des Menschen'). Since 1866 he has edited a periodical entitled 'Investigations of the Physiological Institute at Leipzig' ('Arbeiten aus der physiologischen Anstalt zu Leipzig').

CASTOR OIL extracted from the seeds by means of carbon bisulphide has been found (Apt. Zeit.) to cause silver to blacken.

CARVESTRENE is a new terpene, discovered by Baeble, preserved from the petrified wood of trees of the Carvica, is optically inactive, boils at 178°, and yields inactive halogen compounds. Presumably it is the optically inactive modification of sylvestrene.

CARBON MONOXIDE is found by N. Gréhan ('Compt. rend.') to be produced as one of the products of combustion of carbon and electrical arcs, and in confined space has caused illness among the workmen employed at electric light stations.

NOTICES, LETTERS, AND ANSWERS TO CORRESPONDENTS.

Communications for the current week's Journal should reach the Office, 17, Bloombery Square, London, W.C., addressed "Editor," Not later than the first Post on Wednesday. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING. Telegraph Address: "Pharmaceutical Journal, London." Advertisements (except for the "Exchange" column) orders for copies of the Journal, and Instructions from Subscribers respecting transmission of copies, should not be addressed to the Editor, or delay will be caused. See directions on reverse of first page.

Correspondents who wish to be taken of their communications must write in ink on one side of the paper only, and address the editor, not necessarily for publication. No notice can be taken of anonymous communications. Drawings for illustrations should be done with pen and ink (Chinese), and consist of clean, sharp lines, without shading. They should also be sent twice the desired size, so as to allow for reduction. Names and formule should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

"Queries will be replied to as early as possible after receipt, answers of sufficient general interest being given under the heading Notes and Queries."

ANSWERS.

ALFRED GREEN.—The book is published by Young J. Pentland, 11, Tervot Place, Edinburgh, at 6s. 6d.

D. HOOPER.—Nothing definite appears to be known concerning the origin of the word. In Muriel's New English Dictionary the following occurs:—"Caliator or Caleator.—In Caliator (a) wood, a dye-wood from the Coromandel coast, identified by some with red sauloo wood. 1657 Lond. Gaz., No. 2689.2. Of Caleators I know not."

It may be that the term was derived from the Jew's Ray, and may also be derived from a proper name. The Centenary Dictionary says, "Sometimes confounded with red sauloo wood."

PHARMACIST.—Your inquiry should have been addressed to the Editor. A frequent source of trouble in making the ointment is the presence of cotton-seed oil as an impurity in the olive-oil used. The temperature should also be carefully regulated. If vaselin be used, you will have an unnecessary emulsion. The whole process is too much different from what is required. You will probably find also that the acid liquor tends to separate.

CORRECTIONS.

First Examination.—The Registrar asks us to point out that the figures in the final column on page 944 were disarranged in making up the page last week. The full list of candidates who failed at Southampton was 4, at Worcestor 1, and York 7.

Review.—The name of the publisher of Munkät's 'Prescribing and Treatment in the Diseases of Infants and Children,' on page 963, should have been given as Young J. Pentland, Edinburgh and London.

Publications Received.

[Publishers are requested to state the price of books sent for review.]

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Bird, Brathwait, Dutton, Ettes, Gerrard, Hill, Hindle, Holloway, Hooper, Laing, Macartney, Martin, Miller, Moffatt, Pratt, Shapley, Skinner, Thompson, Turner, Unney, Will, Worth.
ANNUAL REPORT OF THE COUNCIL.

The fifty-fourth financial statement now submitted is sufficiently explanatory to render any detailed reference to the various items of account unnecessary. The special payment of £2000, on account of the extension of the Society’s premises in Edinburgh, has been made out of revenue of the year.

Examinations. The number of candidates who presented themselves for the First examination during 1894 was 1641, an advance of 52 on the number recorded in the preceding year. The percentage of rejections, which was 60–37 in 1893, rose to 61–15, but is still below the average for the past five years. Minor examination, 1410 persons came before those engaged in teaching (in London, and 440 in Edinburgh), and 886, or 62–83 per cent., failed. The percentage of failures is the highest for this examination in recent years.

The number of candidates for the Major examination has not increased, 147 persons having been examined last year, as against 152 in 1893. The percentage of failures was nearly 50 per cent.

At the last appointment of the Boards of Examiners, certain changes in their constitution came into operation which will it is hoped prove beneficial. The members of the Boards are now only eligible to hold office continuously for a period of four years, and teachers of Chemistry and Botany have been appointed members of the Boards as examiners in those subjects. The Council has been fortunate in obtaining the services of Professors Percy Frankland, McLeod, Reynolds Green, and Mr. Seward, on the Board for England and Wales, and Professors Geddes and Gibson on the Board for Scotland.

The Government Visitor, Dr. Stevenson, in his report on the examinations in London for the year ending March 31, 1895, refers specially to the number of failures in the First examination as indicating that the majority of the candidates have had a very defective preliminary education. He considers the examination by no means a severe one for youths, but remarks that, unfortunately, many of the candidates appear to be young men already engaged in the business of pharmacy. With regard to the changes in the personnel of the Board, Dr. Stevenson expresses the opinion that the introduction of those engaged in chemistry and botany is likely to work well and to the advantage of candidates, since there is no one so well fitted to examine and gauge the knowledge of students as he who is engaged in teaching.

Libraries and Museums. A considerable increase is to be noted in the use made of the Library in London by members and associates who are unable from various causes to personally visit the Library. The outward carriage of books is paid by the Society, and the Librarian's account for transmission of books is thus to a large extent a measure of the value of the Library to those connected with the Society. It is, therefore, satisfactory to learn that the amount paid during 1894 on this account was the highest for the past four years. The Council has by purchase of current books, and in other ways, endeavoured to keep the libraries of the Society well

abreast of pharmaceutical and scientific progress, and its efforts have been supplemented by donations of books and periodicals from public scientific bodies at home and abroad, as well as from private individuals. By the rearrangement of rooms in Edinburgh consequent upon the completion of the Society's new Hall and Laboratories, the somewhat limited library and museum accommodation will be extended.

In the Museum in London arrangements have been made to accommodate the largely increased number of medicinal plants in the Society's Herbarium. A complete catalogue of the Herbarium, including the indigenous British plants, has been prepared, and will probably be ready for distribution at the beginning of next session. It has become evident, however, that no catalogue, unless issued at very short intervals, can keep pace with the rapid growth of the Museum, and it is therefore proposed to issue, as an appendix to the existing catalogues, an annual "Museum Report," in which a full list of the donations of the current year will be given, together with explanatory notes and bibliographical references concerning them.

School. The 53rd Session of the Society's School was opened on October 3, 1894, by an address to the students of the School of Pharmacy and their friends, by Mr. Walter Hills, a member of the Council. Mr. Hills chose for the subject of his address the influence of the Society on pharmaceutical and chemical education in Great Britain during the past fifty years. Among those present at the meeting were Sir Richard Quain, F.R.S., President of the General Medical Council, and Sir A. B. Garrod, F.R.S., both of whom expressed their appreciation of Mr. Hills' remarks.

The evening meetings of the School in London have been efficiently maintained during the past session, and most of the sciences allied to pharmacy are embraced in the series of papers read thereat. Botany was represented by Professor J. Reynolds Green, Sc.D., on "The Nervous System in the Vegetable World," and by a paper on the Dipoterocarpaceae by one of the Society's most distinguished Corresponding Members—Sir Dietrich Brandis, K.C.I.E., F.R.S. Professor Greenish contributed to the histological knowledge of ipesacuanha root, and Mr. E. M. Holmes gave valuable notes on "Eucalyptus Oil" and "Opoponax." Mr. J. C. Umney also reported on the characteristics of a false Buchu. In chemistry Dr. Paul and Mr. A. J. Cowley detailed the results of their investigations on the chemistry of ipesacuanha; and the paper by Mr. R. A. Cripps on "Standardised Preparations of Belladonna," concluded the work for the session.

In Edinburgh a useful series of papers has been provided, the contributors being Dr. Stockman, Maser, Booth, D. Brown, D. Rainey Brown, Cowie, A. J. Day, Dott, J. T. Fraser, W. I. Glass, Lunan, Lyon, Maben, Mackenzie, Stephenson, and W. Swan.

Pharmacopoeia. Reference was made in the last Report of the Council to the probable issue of a new British Pharmacopoeia, and it was intimated that the co-operation of the Pharmaceutical Society in the compilation of that work would again be invited by the Medical

AUDITORS' REPORT.

We, the undersigned Auditors, have examined the accounts of the Pharmaceutical Society of Great Britain, as presented in the Financial Statement, Benevolent Fund and Orphan Fund Accounts, and find them correct. We have inspected the Deeds relating to the House Property and Ground Rents named below, and also find that there were standing to the account of the Society at the Bank of England, and in the hands of the Society's Bankers, on the 31st December, 1894, the following, viz.:

Council. The official invitation has been received, and at the Society's Council Meeting in February a Pharmacopoeia Committee was appointed to assist the Committee of the Medical Council in carrying out the work in connection with the new edition of the Pharmacopoeia. The following were appointed.—The President, Vice-President, Dr. W. Inglis Clark, Messrs. Ekin, Walter Hille, Martin, Martindale, Charles Unny, with Professor Greenish as Secretary to the Committee.

Council.

The constitution of the Council has not been much altered during the year.

Mr. T. P. Goatling was elected in May in place of Mr. Marshall Leigh, who did not offer himself for re-election; and the vacancy occasioned by the resignation of Mr. A. C. Abraham has been filled by the election of Mr. W. Warren. The Council has also to record with regret the resignation of Mr. Richardson on account of ill health.

Research.

The Annual Report of the Research Committee was presented to the Council in May.

Legislation.

When the last Annual Report was submitted allusion was made to several important law cases which were then pending. Particular interest attached to the appeal in the Edinburgh High Court of Justiciary. The appellant, who was the unregistered assistant of a medical man keeping an open druggist's shop, sought to reverse a judgment of the Sheriff's Court by which he was convicted of a breach of section 15 of the Pharmacy Act, 1868. The case for the appellant was argued before a full sitting of the Court, comprising the Lord Justice-General, Lord Justice-Clerk, Lord Adam, Lord Kyllachy, Lord Kincairney, and Lord Stormonth-Darling. The appeal was dismissed, the Court following the decision given in the English Courts in the case of this Society v. Wheelon.

As a consequence, the words "any person who shall sell," in section 15 of the Pharmacy Act, 1868, have now received the same interpretation in Scotland as in England.

In the case of the Society v. Armson, in which the defendant, a grocer, was convicted for the sale of a proprietary preparation containing one-tenth of a grain of morphine to the fluid ounce, the Court of Appeal confirmed the decision of the Court of Queen's Bench, and of the County Court Judge.

As illustrating the difficulties experienced by the Council in its efforts to secure obedience to the law, reference may usefully be made to the case of the Society v. Hornsey. The defendant, a watchmaker and jeweller, was proceeded against under section 15 of the Pharmacy Act, 1868, for illegally keeping open shop for the retailing of poison, and evidence was adduced of his having sold a preparation of corrosive sublimate. The Exeter County Court Judge gave verdict for the defendant, however, on the ground that "open shop" in the Act meant an open chemists' shop, and that defendant had not kept such a shop. The principle involved seemed to the Council so important that an appeal was by their instructions immediately lodged against His Honour's judgment. On the matter coming before Justices Cave and Wright, in the Queen's Bench Divisional Court, the appeal was allowed, their lordships agreeing that the defendant by using a shop for retailing poison to any member of the public who might ask for it was keeping an "open shop" within the meaning of the Pharmacy Act, 1868.

In the matter of patents the Council has been kept carefully apprised of the nature of medicinal preparations which have passed the Great Seal. In four instances the Society has been successful in securing the revocation of patents granted in respect of preparations containing scheduled poisons. The procedure in the Chancery Court involves heavy expense to the patentees, as well as to the Society, and it is hoped that a knowledge of this fact may render proprietors of nostrums less eager to resort to the Patent Office with their preparations.

Pharmacy Bill.

The Council after earnest consideration has decided that it is hopeless to go to Parliament in the present state of public business, and resolved not to introduce any measure this session. It should be clearly understood, however, that it is not intended to abandon the effort to obtain further powers, but merely to postpone the attempt until there is a more reasonable prospect of success than exists at present.

Weights and Measures.

A communication has been received from the London Chamber of Commerce directing attention to the present state of the law relating to weights and measures, and asking the Council's support to a Bill drafted by the Chamber to remedy the defect. The Council resolved to support the measure, which had for its object the removal of the restriction prohibiting wholesale druggists and others from using metric weights and measures. Subsequently the Bill was referred to a select committee of the House of Commons, and the Council has made an application to be allowed to give evidence before that Committee. The President and Mr. Martindale have been appointed to represent the views of the Council on the subject.

North British Branch.

The report of the Executive of the North British Branch was submitted to the Council at its last meeting, and gives details of the work carried out by the Executive during the past year.

New Premises.

A new branch of the Society's premises in Edinburgh, necessitated by the continual growth of the work in Scotland, were completed last autumn, and the new examination hall and laboratories were formally opened at a conversazione and reception, which was held at 36, York Place on November 30, by the President and Council, assisted by Mr. J. Laidlaw Ewing, Chairman of the Executive of the North British Branch. A full description of the additional accommodation provided is recorded in the Pharmaceutical Journal of December 1. Since the official celebration of their completion, the new premises have been used for the January and April examinations and the evening meetings. The satisfaction afforded by the result is valuable testimony to the care and forethought with which the Executive—under the able guidance of its Chairman—has carried out the work entrusted to its charge. The laboratories are well adapted to the requirements of the examinations, and the Society now has ample scope for efficiently carrying on its work in Scotland.
The Council regrets to have to report a slight diminution in the annual income from subscriptions to this Fund. In 1893 the sum received amounted to £1712 18s. 6d.; last year it was £1702 19s. 7d. This is not a large falling off, but it would seem that the generous policy hitherto pursued of granting relief beyond the limit of strict solvency in expectation of increased support from chemists and druggists is one that cannot be followed in future without grave anxiety. The total amount spent in relief during 1894 was £2743 4s.—only £2 less than in the previous year. Four additional annuitants were elected in December last, and the list now comprises forty-six names. The payment of annuities involves an annual charge of about £2900, and represents, at 3 per cent., the product of a capitalised sum of more than twice the amount now standing to the credit of the Fund. It is evident that in order to continue its good work, the Fund must either receive augmented support from the trade or restrict the grants of assistance to deserving applicants. In donations and legacies the Council has to acknowledge the receipt of £753 5s. during 1894, and from this it does the urgent and growing necessities of the Fund it ventures to express the hope that this form of benevolence may commend itself to those who have prospered in pharmacy.

The names of the preparations are Latin, and the principles upon which they are based are the same as those adopted for the previous edition.

The strength of the acids has been fixed, as in the second edition, somewhat empirically; acetic, hydrochloric, and nitric acids contain 25 per cent., dilute hydrochloric, dilute sulphuric, and phosphoric acid 10 per cent. of the corresponding anhydrides. This edition of the Norwegian Pharmacopoeia, like the second, is peculiar in directing bitter almond water and kermes to be artificially produced by admixture.

For only a few drugs, as cinchona bark, opium, have methods of assay been adopted; no extracts are directed to be assayed or tested qualitatively for alkaloid or glucoside.

Several extracts which in the German Pharmacopoeia are soft, in the Norwegian are dry, as for instance gentian, belladonna, henbane (the latter two with addition of sugar of milk).

An important change has been made in the maximal doses; these in the second edition were given in drops for all fluid preparations, whilst in the third edition they are uniformly stated by weight. The majority are identical with those of the German Pharmacopoeia.

The following details of tests and formulae, some of which were included in the second edition of the Norwegian Pharmacopoeia, will probably be of interest.

**Ether Spirituosus Camphoratus** (camphor drops).—Camphor, 15; ether-alcohol, 85.

**Aqua Amygdalis Amara** is prepared by mixing 50 parts of hydrocyanic acid (2 per cent.), 4 of oil of bitter almonds (free from hydrocyanic acid), 146 of spirit, and 800 of water; contains 0.1 per cent. of hydrocyanic acid.

**Aqua Choloroformi**.—Chloroform, 1; water, 199.

**Aqua Cinnaomi Spirituosa**.—Oil of cinnamon, 2; dilute spiritis, 499; water, 499.

**Aqua Aromaticæ Extrarmornae**.—Etheroil, 1; hot water, 999.

**Aqua Rosa**.—Otto of rose, 1; hot water, 4000.

**Colloidum Elasticum**.—Colloidum, 99; glycerin, 1; **Decoction Chinæ Acidum**.—Cinchona (saucorubra) bark, 20; dilute (10 per cent.) hydrochloric acid, 3; water to produce 200 of strained liquid.

**Decoction Chinæ cum Senega**.—Cinchona bark, 7; senega root, 3; water to produce 100.

**Eluctuarium Aperiens.**—Biteratre of potassium, 6; powdered semina, 14; purified tamarin pulp, 30; syrup of marron, 50.

**Emplastrum Adhesiveum**.—Load plaster, 80; yellow wax, 10; mastiche, 10.

**Emulsio Camphorae**.—Powdered camphor, 1; mucilage, 40; water, 150.

**Extractum Belladonæ** (extractum atropis).—Powdered belladonna leaves are exhausted with dilute spirit, the tincture evaporated to dryness, and the residue mixed with one-third of its weight of sugar of milk. (Extract of henbane is prepared in a similar manner.)
Ferrum Reductum should show 88 per cent. of metallic iron when tested in the following manner: 0.5 grammes reduced iron is mixed in a flask with 2 grammes of iodine, 1.5 grammes of iodide of potassium, and 30 grammes of water; after a time the liquid is filtered off and should not colour chloroform violet when shaken with it.

Glacies is adopted without further description.

Granulae Dioscoridis (arsenic pills).—Very finely powdered arsenious acid, 1; powdered sugar, 10; powdered sugar of milk, 10; powdered gum, 10, with sufficient water to form 1000 pills (each containing 0.001 gramme arsenious acid).

Infusum Rhe Alkalinum (rhubarb drops).—Sliced rhubarb root free from powder, 25; bicarbonate of sodium, 3; water, 170; macerate twelve hours, strain, boil the liquid, cool, make up to 170 with water, and add cinnañan water, 30.

Infusum Seneca Compositum (senna mixture).—Cut senna leaves, 10; crushed coriander, 2; boiling water to produce 70 of strained liquid; in this dissolve manna, 25; tartrate of potassium, 5.

Kermes Minerals.—Oxide of antimony, 1; red sulphide of antimony, 9. The Pharm. Nov. contains also a red sulphide of antimony without oxide.

(EVOLUTION AMONG PLANTS.)

At a recent meeting of the Massachusetts Horticultural Society, a paper, of which the following is an abstract, on "Experimental Evolution Among Plants," by L. H. Bailey, professor of horticulture in Cornell University, Ithaca, N.Y., was read by the author. The speaker prefaced his remarks by saying that all thoughtful persons are now evolutionists, whether they know it or not. They believe in some kind of a transformation of species in the same way that they believe in the gradual unfolding and growth of human institutions. It is by no means essential to a belief in evolution that the person should hold to a single origin of all forms of life.

The speaker then proceeded to consider the question, "Do new species originate now?" The notion that a species, to be a species, must have originated in nature's garden and not in man's, has been left over to us from the last generation—it is the inheritance of an acquired characteristic. John Ray, toward the close of the seventeenth century, appears to have been the first to use the word species in its technical natural history sense, and the matter of origin was an important factor in his conception of what a species is. Linnaeus' phrase is familiar. "We reckon as many species as there were forms created in the beginning." Darwin elaborated the new conception—that a species is simply a congregation of individuals which are more like each other than they are like any other congregation—and with a freedom from prejudice which is rarely attained even by his most devoted adherents, he declared that "one new variety raised by man will be a more important and interesting subject for study than one more species added to the infinitude of already recorded species." The old naturalists threw the origin of the species back beyond known causes; Darwin endeavoured to discover the "origin of species," and it is significant that he set out without giving any definition of what a species is. It is important, when we demand that new species be created as a proof of evolution, that we are ourselves open to conviction that the thing can be done. The fact is that the practice of systematic or descriptive botany is at variance with the teachings of evolution. Every naturalist now knows that nature does not set out to make species. She makes a multitude of forms which we, merely for purposes of existing methods of botanical description and nomenclature, call species.

The speaker then proceeded to show that there has been as wide variation in very many garden plants as there is between accepted botanical species of the same genus.

Species-making forever enforces the idea of the distinctness and immutability of organic forms, but study of organisms themselves forever enforces an opposite conception. The intermediate and variable forms are perplexities to one who attempts to describe species as so many entities which have distinct and personal attributes. So the garden has always been the bugbear of the botanist. Even the lamented A. S. Gray declared that the modern garden roses are "too much mixed by crossing and changed by variation to be subjects of botanical study." He meant to say that the roses are too much modified to allow of species-making. The despair of systematic botanists is the proof of evolution.

If species are not original entities in nature, then it is useless to quarrel over the origination of them by experiment. All we want to know, as a proof of evolution, is whether plants and animals can become profoundly modified under different conditions, and if these modifications tend to persist. Everyone interested knows, as a matter of common observation and practice, that this is true of plants. He knows that varieties with the most marked features are passing before him like a moving panorama. He knows that nearly every plant which has been long cultivated has become so profoundly and irrecoverably modified that people are disputing as to what wild species it came from. Consider that we cannot certainly identify the original species of the apple, peach, plum, cherry, orange, lemon, wine grape, sweet potato, Indian corn, melon, bean, pumpkin, wheat, ohryanthemum, and nearly or quite a hundred other common cultivated plants. It is immaterial whether they are called species or varieties. They are new forms. Here is the experiment to prove that evolution is true, worked out upon a scale and with a definiteness of detail which the boldest experimenter could not hope to attain were he to live a thousand years. The horticulturist is the only man in the world whose distinct business and profession is evolution. He of all other men has the experimental proof that species come and go.—Pharmaceutical Era.
The report of the Government Visitor of the examinations in London, recently received from the Privy Council, was presented. Speaking of the changes in the examiners, Dr. Stevenson expresses the opinion that there has not been any considerable change in the proportion of rejections in the qualifying examination. He speaks with approval of the introduction of examiners engaged in teaching chemistry, physics, and botany as being likely to work well, and to the advantage of candidates. In the Major examination there has been some improvement in the number of papers, and evidence that the candidates have had a better scientific training. At the same time regret is expressed that so small a number of chemists and druggists present themselves for this examination, and that the larger number are content to remain without the higher qualification of pharmaceutical chemist.

On the subject of the Preliminary examination, Dr. Stevenson again refers to the unfortunate fact that many of the candidates are past the age at which it is desirable that this examination should be passed. Coupled with that fact, the large proportion of rejections is evidence of defective education, and of the pressing need for improvement in that part of the qualifying system.

The report of the Finance Committee did not contain any exceptional details, except mention of the receipt of twenty-five guineas from the Chemists' Ball Committee, a sum from a smoking concert at Liverpool, and ten guineas from Mr. Waterall, of Nottingham, as donations to the Benevolent Fund.

On the recommendation of the Benevolent Fund Committee ten grants, amounting in the aggregate to one hundred and five pounds, were ordered to be paid. In moving the adoption of the report the Vice-President referred to the large amount of the grants made on this occasion as showing the need for liberal support, and he expressed satisfaction that subscriptions to the Fund are coming in so well. In connection with the case of Mary Margaret Lewis, who is a candidate for election to the Welsh Girls' School, he mentioned that Alderman Vaughan Morgan has interested himself on her behalf, as well as Mr. Octavius Morgan, the late Member for Battersea, with the result of securing a number of votes which he hoped would lead to her election. Mr. Johnston, in speaking of a grant in a Scotch case said that, though proud of the fact that applications for relief from the Benevolent Fund are rarely made from Scotland, he was not the less pleased to find a deserving case entertained in a good spirit, and he hoped this circumstance would open the hearts as well as the pockets of members and of those outside of the Society. In support of this remark, Mr. Young pointed to the probability of an in-
creasing application for grants as a result of the terrible competition in business, and the absence of any other provision for those who grow old in the service of such enterprises as are now the subject of so many prospectuses.

The annual report of the Research Committee was presented and entered on the minutes upon the motion of the President. Some remarks were made as to the nature of the work carried out in the laboratory, the students working in it, and the financial statement relating to it. The discussion of the motion of which Mr. Martindale had given notice, was taken in Committee, with the result that it was resolved to defer the consideration of the subject for the incoming Council.

On the subject of the investment of funds, it was decided, on the motion of the President, to refer its consideration to a committee. Mention was made of a case of poisoning by soothing syrup, to which attention has been directed by a communication from the Privy Council. A letter from the Plymouth, Devonport, Stonehouse, and District Chemists' Association, relating to the Early Closing Bill, was referred to the Parliamentary Committee. Another letter, from the Registrar of the Pharmaceutical Society of Ireland, asking that the Preliminary examination of that Society should be accepted in lieu of the Society's examination, was referred to the Board of Examiners.

The report of the General Purposes Committee recommended the award of prizes to the candidates named at page 1012. The draft of the annual report, printed at page 993, was adopted, and after the legal portion of the Committee's report had been considered, the Registrar was authorised to take proceedings against several persons who have been reported as infringing the Pharmacy Act.

THE PURIFICATION OF WATER.

At the present day no one doubts the necessity of a constant supply of pure water, but as pointed out by Dr. Guinonchet, in his work on the purification, filtration, and sterilisation of potable waters,* the definition of purity has varied from time to time. The organoleptic characters of a water—odour, flavour, and clearness—do not alone suffice to establish its fitness for dietetic purposes; its chemical properties must also be taken into account, as well as its biological characters. Briefly, a pure water for potable use should be free from solid particles, objectionable matter in solution, and living organisms. In order to meet these requirements, in the case of natural waters, it is almost invariably necessary to filter, precipitate by chemical means, or sterilise by heat or otherwise, or it may even at times be necessary to resort to all three methods. Filters act mechanically for the most part, but (and in some cases to an important extent) may also act chemically. If, too, the particles of which they consist are sufficiently close together microbes may be thus mechanically eliminated. But whilst it would thus appear that the effectiveness of a filter is in direct proportion to the fineness of its pores, it is found in practice that the rate of flow may be reduced so as to cause great inconvenience if the filtering medium be too dense. It is desirable, therefore, in selecting a filter to carefully ascertain its exact capabilities in this respect, so that it may not be called upon to do work beyond its capacity, and thus, maybe, prove ineffectve and create a sense of false security by its use. Dr. Guinonchet enters at length into the consideration of the various points involved in this question before proceeding to deal with the details connected with the filtration and purification of water, and this part of his book is worthy of more than passing attention.

The most effectual means of preventing risks arising from the use of impure water by any community is, of course, to filter and otherwise purify the whole supply at a central station, by means of sand, gravel, etc., in the form of immense beds. A considerable portion of Dr. Guinonchet's work is devoted to this part of the subject, as well as to purification by electricity and by chemical means—chalk, soda, magnesia salts, alum, iron, potassium permanganate, citric acid, charcoal, etc., being employed in the respective processes described. But the more interesting part of the subject, from an individual point of view, is that which deals with domestic filtration, in which the operations are necessarily carried out on a much smaller scale. The processes described are exceedingly numerous, though but few of them are commonly known. Thus, brief descriptions are given of the filter devised by Amy in 1745, in which sponge, cotton, and sand were utilised; of that of James Peacock, an Englishman, who in 1791 took out a patent for a filter in which sand and gravel were employed; Duchesne's filtering stones (1800); Smith, Cucuet, and Montford's filter containing sand, charcoal, and sponge (1806); and numerous variants on these, introduced by later experimenters. The greatest interest, however, attaches to the filters of Chamberland (Pasteur system), and Berkefeld, which have been shown during recent years to be the most effectual in use. The first is in great favour in France, and receives the greatest amount of attention in the book, but both are described and figured under various forms for use on both the large and small scales. The properties of the two, so far as English experiments prove, may be briefly summed up in the statement that whilst the Pasteur-Chamberland filter removes all suspended impurities in water, including bacteria,
over a greater length of time than the Berkefeld,
the latter will deliver a much greater amount of
water in a given period. Moreover, the Berkefeld
filtering cylinders can be made much larger than
the Chamberland cylinders, without risk of imper-
fection or fracture. They are also very readily
cleaned, a point of some little importance when
domestic filters are in question.
Either of these filters, however, in addition to
simple filtration, i.e., removal of suspended impuri-
ties, possesses a powerful sterilising influence, which
is of longest continuance in the case of the Cham-
berland apparatus. If, therefore, the water has been
first rendered free from objectionable soluble con-
stituents by chemical precipitation, subsequent
filtration through one of these filters ensures a
supply of water sufficiently pure for potable
purposes. In certain cases where further steri-
lisation may be necessary, the action of heat can be
resorted to, and it is found in practice that all
organisms may be destroyed by heating the water
to a high temperature or maintaining at a lower
temperature for a certain length of time. Dr.
Guinocchet gives numerous statistics bearing on this
aspect of the matter, and also describes several forms
of ingeniously contrived apparatus for sterilising
water by heating, both on the domestic and larger
scales. Certain of these act on the water under
pressure, and some have attachments for subse-
quently cooling the liquid again and rendering it
palatable. Finally, in concluding the work, which
can be recommended as deserving the notice of
everyone interested in the subject of which it
treats, Dr. Guinocchet suggests that water should
preferably be obtained from springs, but in cases
where rivers and lakes must be utilised the pro-
duct should be carefully purified as far as possible
before being distributed, and domestic filtration
should be resorted to in all cases to ensure the
total removal of microbes that may have been
collected during the passage of the liquid from the
place of distribution.

OPENING OF THE SCHORLEMMER LABORATORY.
The opening of the Schorlemmer Laboratory
last week, as pointed out by the Manchester
Guardian, in many ways an interesting event in
the history of English chemistry, no less than in
that of the Owens College. Professor Schor-
lemmer was the first professor of organic
chemistry in England, and the laboratory founded
in his memory is the first in this country to be
solely devoted to that branch of the science.
Schorlemmer himself was recognised by all who
knew him as a lover of chemistry for its purely
intellectual rewards. He studied it in its more
abstract and its historical aspects, coveting neither
the honour nor the material advantages which lay
within his grasp; and all his life he remained
known but to a few, and relatively poor. ‘‘Never-
theless, his work forms the corner-stone of the
comprehensive theories which within recent years
have given chemists so marvellous a mastery over
the transformations of matter, and have directly
led to those triumphs in chemical industry which
now employ many thousands of workers.’’

Transactions of the Pharmaceutical
Society of Great Britain.

MEETING OF THE COUNCIL.
Wednesday, May 8, 1889.

Present—
MR. MICHAEL CARTMIEGE, PRESIDENT,
MR. WILLIAM GOWEN CROSS, VICE-PRESIDENT,
Messrs. Allen, Atkins, Bottle, Gostling, Grose,
Hampton, Harrison, Hills, Johnston, Martin, Mar-
dale, Newsholme, Schacht, Southall, Storrar, Warren
and Young.
The minutes of the last meeting were read and con-
ﬁrmed.

RESIGNATION OF MR. J. G. F. RICHARDSON.
The President read a letter from Mr. H. N. B.
Richardson, on behalf of his father, tendering his
resignation as a member of the Council, which he did
with great regret, but he felt that the state of his health
would not allow him to continue to hold office longer.
He would, therefore, move ‘‘That this Council regrets
to hear of the continued indisposition of Mr. J. G. F.
Richardson, and in accepting the resignation of his
seat on the Council after sixteen years’ service, desires
to express the hope that with rest his health may
improve.’’ Mr. Richardson was one of the earliest students
in that institution, and one of the earliest examined
men who became a member of the Council. His
knowledge of the branches of science bearing on
pharmacy was distinctly above the average, and in
matters of education especially, his services on the
Council would be much missed.
The motion was seconded by the Vice-President,
and the resolution carried unanimously.

DEATH OF A FOUNDER.
The President reported the death since the last
meeting of the Council of one of the founders of the
Society—of whom there were now only nine left—in
the person of Mr. Darling, of Manchester. Person-
ally he had not the honour of Mr. Darling’s acquain-
tance, but he had some recollection of the work which
he had done. His son was a distinguished student in
natural science at Owens College, and was regarded
in the north as a highly intellectual young man.
The father, whose death they regretted, was a type of
what was known as the old school of pharmacists.
He was reputed for a knowledge of many things, and
what he did know was of a thorough character.

CORRESPONDING MEMBERS.
The President moved the election, as correspond-
ing members, of Dr. Schweinfurth, Cairo, and Robert
Thomson, late Superintendent of the Botanic
Gardens, Jamaica, their names having been suspended
in the Library for a month in the usual way. They
were both distinguished men, and he had no doubt
would be useful members of the Society.
DIPLOMAS.
The undermentioned being duly registered as Pharmaceutical Chemists, were granted diplomas stamped with the seal of the Society:—

Banks, Edward Herbert Hardy
Brown, William James
Bryant, Nicholas John Andrew
Cartier, William Henry
Elliott, Oliver Thomas
Gates, Colvin
Gaul, Ernest George
Grier, James
James, David Griffith
Morrey, George
Pearce, Seymour Rowland
Prior, James Siddall
Thorp, Ernest
Tree, John
White, Henry Fox

ELECTION OF MEMBERS.
Pharmaceutical Chemists.
The following having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:

Bryant, Nicholas John Andrew ... Truro
Elliott, Oliver Thomas ... Leicester
Gates, Colvin ... Glasgow
Gaul, Ernest George ... Kensington
Lake, William Frank ... Modbury
Morrey, George ... Holborn
Pearce, Seymour Rowland ... Brixton
Prior, James Siddall ... Melton Mowbray
Thorp, Ernest ... Southport
Tree, John ... Morpeth

ELECTION OF ASSOCIATES IN BUSINESS.
The following having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates" of the Society:

Bamford, William ... Rochdale
Baxter, Gilbert ... Blackburn
Bayley, Edward George ... Eastbourne
Bonnett, Frederick ... Newton
Brearley, Richard Samuel ... Greenwich
Buckley, John Davies ... Woolwich
Cameron, Lewis ... Collin’sburgh
Carmichael, Matthew ... Croydon
Cleghorn, James ... York
Dampney, John ... Norwood
Dawson, Alexander Fraser ... Edinburgh
Dean, George Saville ... Rochdale
Douglas, William Boyce ... Egham
Edwards, Henry Charles ... Hastings
Fisher, George Robert ... Leamington Spa
Flint, Francis Bramwell ... Manchester
Floyd, Harry Victor ... Haverhill
Forbes, Alexander ... Queensland
Forbes, Robert ... Newcastle-on-Tyne
Furnival, Charles Edward ... Leicester
Giles, William ... Westward Ho!
Gould, William ... Portsmouth
Gregory, George Henry ... Scarborough
Hailstone, William Edward ... Camberwell
Heneshaw, Charles James ... Skelmersdale
Hewitt, Charles Herbert ... Sheffield
Jenkins, Morris William ... St. Clears
Jones, David Lloyd ... Newport
Le Seel,er, Thomas John ... Jersey
Lloyd, James Herbert ... Bedford
McKellar, Arthur ... Glasgow
McLeod, Louis ... Inverness
Marratt, Thomas ... Lewisham
Maxwell, Peter Hamilton ... Harrogate
Parker, Edward ... Scarborough
Paterson, William C. T. ... Cirencester
Peacock, John Rutherford ... Glasgow
Pennington, John Richard ... Workop
Rawsthorne, Reginald ... Wiltshire
Rideal, Frank ... Minnow
Sharma, Herbert Brough ... Potter’s Bar
Shaw, Thomas Alexander ... Leeds
Sinclair, John Gordon ... Nottingham
Smith, Joseph Henry ... Moreton-in-Marsh
Smith, Percy ... Croydon
Turnbull, James ... Blackpool
Turner, John Edward ... Reading
Wilkins, Charles Henry ... Southampton
Wilkinson, William ... W. Kensington

ELECTION OF ASSOCIATES.
The following having passed the Minor examination, and tendered, or paid as "Students," their subscriptions for the current year, were elected "Associates" of the Society:

Attenborough, H. Langley ... Leamington
Bawson, Sidney ... London
Bateson, Alfred Campbell ... Kendal
Brown, Harold ... Southport
Brown, Harold Edwin ... Hull
Callaway, James Thomas ... London
Cashmore, Montague ... London
Compton, Richard William ... Leicester
Cooper, Burton Fred. John ... London
Cuff, Sidney Wilmott ... New Barnet
Curry, Frank ... Dorking
Dawson, Hy. Gray Woodhouse ... Derby
Dawson, Peter ... Glasgow
Edwards, William Richard ... London
Ferguson, Howard ... Chesterfield
Flower, John Scott ... Wakefield
Forster, Horace Reginald Wm. Chatham
Forsey, Douglas Millar ... Edinburgh
Fraser, Henry ... Aberdeen
Fuller, Herbert Emery ... Norwich
Giles, W. John ... High Wycombe
Greaves, Ernest Walter ... Ironville
Gwinn, Frederick Walter ... Stratford
Harries, John Davies ... Milford Haven
Heden, Joseph Henry ... Kineton
Hemming, William Hubert ... Birmingham
Hull, John Brier ... Halstead
Hunt, Henry Lionel ... Bath
Ibbotson, Oswald ... Wakefield
Jones, John Emrys ... St. Asaph
Kinsman, William Ernest ... Devonport
Knowles, Charles John ... Forest Gate
Marsh, Albert ... Crewkerne
Mann, William Henry ... Peterborough
Merry, Charles ... Stonehouse
Moore, Francis Ayrton ... London
Mould, John Salmon ... Louth
Mundell, Stephen Robson ... Leeds
Oliver, Gwynn Emrys ... London
Palmer, Charles Richmond ... Tamworth
Pratt, William ... Shipston-on-Stour
Prype, Harry Kenneth ... Brantree
Read, Harold McLean ... Alnwick
Robinson, Ernest Temple ... Harrogate
Sayers, Frederick William ... Ardingley
Seath, John Alexander ... Teddington
Simm, Herbert Frank ... London
Smart, Gordon ... Hunts
Snee, William Kennard ... Okehampton
Sparks, Percy .............. Ipswich
Stoddart, James George Young............. Edinburgh
Wigdery, Ernest .............. Burnham
William, Robert Wherry .............. Peterborough
Young, John Arthur .............. Newport (Mon.)

ELECTION OF STUDENTS.

The following having passed the First examination, and tendered their subscriptions for the current year, were elected "Students" of the Society:

Adams, John .................. Uxbridge
Cameron, John Sinclair .............. Burton-on-Trent
Castelow, Walter Thomas .............. Leeds
Chandler, Martin William .............. Swindon
Chapman, Edgar Marsh .............. Scarborough
Clarke, Charles William .............. Kensal Rise
Coates, Richard .............. Bradford
Cox, Thomas Finchett .............. Edinburgh
Creacraft, Richard Preston .............. Nottingham
Daniels, Herbert Joseph .............. Leicester
Desmond, Dennis W. A. .............. London
Farr, Francis William .............. Fasley
Hart, Edward George .............. Sheerness
Herd, Robert Stark .............. Kirkcaldy
Hunt, George Paul Allen .............. Ipswich
Hunt, Harold Edward .............. Poole
Ingle, George Edward .............. Whitlessea
John, Morgan .............. Treorchy
Jones, Thomas Henry Owain Upper Bangor
Jones, Thomas Pugh .............. Talley
Logie, John Moffat .............. Arbroath
Low, Charles Pearson .............. Chester-le-Street
Lownsborough, Robert E. .............. Scarborough
Marooyln, Henry M. .............. Ramsgate
Muscoot, Rowland William .............. Birmingham
Odgers, William Henry .............. Wrexham
Oldham, G. W. N. .............. Farnham
Owen, William Hibbert .............. Earlestown
Flowright, Alfred .............. London
Potter, William .............. Plaisot
Scott, John Irwin .............. Bootle
Scott, John Wilson .............. Birmingham
Smith, Frederick A. Upaher Birmingham
Strong, James Branford .............. Deal
Todd, John William .............. Leicester
Wade, Walter Colin .............. Sidcup
Williams, John .......... Llanelli
Williamson, Joseph Bertram Liverpool
Wright, Joseph .............. Bridgetown
Yapp, Helen M. .......... Birmingham

RESTORATIONS TO THE REGISTER.

The names of the following persons who have severally made the required declarations and paid a fine of one guinea were restored to the Register of Chemists and Druggists:

Charles Estcourt Day, 26, Girlington Road, Manningham, Bradford.
Solomon Gervas Maw, Woodhouse, near Sheffield.
George Edward Rogers, 1, Cheadon Villas Edmondston.

Several persons were restored to their former position in the Society upon payment of the subscription for the current year and a nominal restoration fee of one shilling.

REPORT OF THE EXECUTIVE OF THE NORTH BRITISH BRANCH.

This report was as follows:

"The Executive of the North British Branch has now to submit the following report on the work of the year March, 1894, to March, 1895:—"

"At a meeting of Executive held on April 19, 1894, it was arranged that the annual election should take place on Thursday, June 21, 1894, and the present Executive was accordingly elected at a meeting of members and associates in business of the Society residing in Scotland, held on the above date.

"The Executive has held three meetings during the year. At the first meeting, on June 28, Mr. James Laidlaw Ewing, Edinburgh, was elected Chairman, and Mr. Charles Kerr, Dundee, Vice-Chairman, and the resident members were appointed a General Purposes Committee to attend to business arising between meetings of Executive.

"The General Purposes Committee has met five times and has had charge of the work connected with the completion and opening of the new premises and the arrangements for evening meetings.

"At the meeting of the Executive in June, 1894, a special committee for the nomination of Examiners was appointed, and reported to the meeting of Executive in November, when the following were nominated for election by the Council as the Board of Examiners in Scotland for 1895, viz.:—Professor Patrick Geddes, Dundee; Professor John Gibson, Edinburgh; Peter Bos, Edinburgh; David Brown Dott, Edinburgh; Jonathan Innes Fraser, Edinburgh; James Jack, Arbroath; Thomas Maben, Hawick; and John William Sutherland, Dumfries.

"The financial statement for the year, up to December, 1894, showing a total expenditure of £3114 12s., as compared with £1098 10s. 11d. for the previous year, has already been forwarded to the Council. The foregoing includes the exceptional expenditure of £1861 15s. for new buildings, and £53 5s. 9d. for expenses of reception at opening of Hall and laboratories in November.

"The following particulars indicate that the departments connected with the Branch continue in a satisfactory state:—"

"The Examinations.—The Board has conducted the January and April examinations in the new Hall and Laboratories, and the Executive has pleasure in reporting that the new premises have been found admirably adapted for the convenient and efficient carrying out of this important part of the Society's work.

"Experience has suggested a few minor alterations and improvements, and a small committee of the Board of Examiners has been appointed to confer with the Chairman and Assistant-Secretary with a view to having these suggestions given effect to.

"There has been a decrease in the number of Major candidates, ten as compared with thirteen, but an increase in the percentage of passes, 60 per cent. as compared with 30·8 per cent. The number of Minor candidates shows an increase, 413 as compared with 305, and the percentage of passes also indicates a slight improvement, 42·17 per cent. as compared with 40·25 per cent.

"Evening Meetings.—The first evening meeting of the session took the form of a reception by the President and Council, and conversations, at the opening of the new premises in November. It was attended by
upwards of 500 ladies and gentlemen, and was eminently successful. The ordinary evening scientific meetings have been continued, and have been attended with success. Two such meetings have been held, and a third has been arranged to take place on April 28. On account of the heavy extra work connected with the fitting up and arranging of new premises for examinations it was decided to have no evening meetings during December and January.

"It has been found that the New Hall is a great advantage for the holding of these meetings. The meeting held on March 22 would have more than twice filled the old Board room, where the meetings have hitherto been held.

"Library.—The Library continues to grow by the addition of new and standard books on pharmacy and the collateral sciences, mainly by purchase and a few as donations. The accommodation in the present library is now entirely taken up, and an extension has become imperative.

"It is proposed to obtain this by removing the Library to the old Board room on the second floor, which is well adapted for the purpose.

"The Library continues to be frequently consulted by university and extra-mural lecturers and others engaged in teaching science and in scientific research who cannot become members of the Society, and these have frequently expressed their high appreciation of the privilege.

"The number of volumes lent out during the year is seen from the following table:—

<table>
<thead>
<tr>
<th>Year</th>
<th>Number of Volumes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1894</td>
<td>1348</td>
</tr>
<tr>
<td>1895</td>
<td>1223</td>
</tr>
</tbody>
</table>

Increase 123

"The Library is also very largely made use of by members, associates, and students for purposes of reference. The circulation of books to provincial readers shows an increase. During the twelve months (1893-94) 141 volumes were circulated to readers outside Edinburgh and Leith. During the twelve months (1894-95) 130 volumes were so circulated, being an increase of sixteen. The Executive is still of opinion that this department of the Library's usefulness might be greatly extended with much advantage to members, associates, and students residing in the provincial districts."

"Museum.—The Executive has again to record thanks to several donors of interesting specimens, and some duplicate specimens have also been received from Bloomsbury Square. The students' specimens are in good order, but it is intended to make improvements in this department in connection with the proposed re-arrangement of the Museum after removal of the Library from the ground floor.

"The attendance at the Society's Museum and Library continues to keep up, and though no accurate record of the precise number can be given, it is estimated that about 3000 visited them during the year.

"There can be no doubt that there is a growing appreciation among Scotch pharmacists of the attention shown to them by the Council in providing premises in Edinburgh, admirably equipped for the advancement of those interests represented by the Society.

"House.—The chief feature of the year in reference to the Society's House has been the completion and opening of the new premises, which are now well furnished and in good order. The other parts of the Society's premises it is proposed to rearrange, and a committee has been appointed to prepare a special report for the consideration of the Council.

"JAMES L. EWING, Chairman.

"Edinburgh, April 19, 1895."

The President moved that this report, which contained many interesting details, be received and entered on the minutes.

Mr. Storrie said he believed the Society was very well served at the present time by the North British Executive, more especially, during the last two years, by the Chairman and Assistant-Secretary. He was desired on behalf of the North British Branch to thank the Council for the very complete and handsome manner in which the premises in Edinburgh had been finished. They had now a suite of rooms which for completeness and convenience were not even second to those in Bloomsbury Square, and he hoped they would be largely used, and by a higher class of candidates even than they had hitherto.

The resolution was carried unanimously.

---

THE SOCIETY'S EXAMINATIONS.

The President announced that the members would find on the table the report of Dr. Stevenson, the visitor to the Privy Council, on the Society's examinations in England and Wales, as follows:—

"Report on the Examinations held by the London Board of Examiners of the Pharmaceutical Society of Great Britain during the year ending March 31, 1895.

"To the Lords of the Council,

"My Lords,—I have to report that during the year ending March 31, 1895, I have attended twelve examinations of the London Board of Examiners of the Pharmaceutical Society of Great Britain.

First or Preliminary Examination.

<table>
<thead>
<tr>
<th>Candidates examined</th>
<th>1562</th>
</tr>
</thead>
<tbody>
<tr>
<td>Who passed</td>
<td>726</td>
</tr>
<tr>

<tr>
<td>Failed in Latin</td>
<td>519</td>
</tr>
<tr>
<td>English</td>
<td>409</td>
</tr>
<tr>
<td>Arithmetic</td>
<td>791</td>
</tr>
</tbody>
</table>

These figures, when compared with those of 1894, show that the failures have considerably increased, more especially in arithmetic. I have read many of the candidates' papers, and having compared the marks assigned to them by the Examiners with the standards adopted for 'pass' and 'rejection,' I am of opinion that a very moderate knowledge of the subjects of the examination will enable a candidate to pass. There are a very large number of candidates who present themselves at this examination of very defective education. One in six of the candidates failed in every subject. This examination is by no
means a severe one for youths, but unfortunately many of the candidates are, I believe, young men already engaged in the business of pharmacy.

Minor Examination.

<table>
<thead>
<tr>
<th>Candidates examined</th>
<th>Numbers</th>
<th>Percentages</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1002</td>
<td></td>

<tr>
<td>dispensing</td>
<td>169</td>
<td>16-9</td>
</tr>
<tr>
<td>obtaining aggregate marks for a pass</td>
<td>71</td>
<td>7-1</td>
</tr>
</tbody>
</table>

"Here there is a slight increase in the percentage of passes. There have been considerable changes in the list of examiners, but judging from the results of the January examination, when the new examiners came into office, there has been no considerable change in the proportion of rejections. The introduction of those engaged in teaching chemistry, physics, and botany into the staff of examiners at this and the Major examination is, I believe, likely to work well and to the advantage of candidates, since there is no one so well fitted to examine and to gauge the knowledge of students as he who is engaged in teaching science. I shall watch the further results of the change with interest."

"I can speak in high terms of the increased care and skill with which the examiners for the most part discharge their duties.

Major Examination.

<table>

</tbody>
</table>

"Here, again, there is an improvement in the number of passes, and the scientific training of the candidates has evidently undergone an improvement. It is to be regretted, however, that so small a number of chemists and druggists present themselves for this examination, but content themselves with passing the Minor, which is the qualifying examination, and are content to remain apparently destitute of the higher knowledge demanded to enable them to assume the higher title of pharmaceutical chemist."

"I am, my Lords,

"Your obedient servant,

THOS. STEVENSON,

"March 14, 1895." — Visitor."

FINANCE REPORT.

The report of this Committee was read by the Secretary.

The President, in moving the adoption of the report, said the receipts, as was usual this month, were somewhat larger than usual, members', associates', and students' subscriptions coming in to the extent of something like £1000. The Benevolent Fund was fairly well supported, their friends having sent in some £1800. Amongst the donations to this fund during the year were 25 guineas from the chemists' ball, a sum from a smoking concert at Liverpool, and 10 guineas from Mr. Waterall, of Nottingham, one of their old members, for which they all felt very grateful. The payments called for no special remark, except that the expenses both of the College of Preceptors and of the technical examinations were included in the account. The Orphan Fund remained practically as it was.

The report was agreed to unanimously.

BENEVOLENT FUND COMMITTEE.

The report of this Committee included a recommendation of the following grants:

- £10 to a registered chemist and druggist (60) who had failed in business, and has since been acting as assistant, but is now out of employment. (Bristol.)
- £10 to the widow (81) of a pharmaceutical chemist member, who is dependent on her son, who has a wife and family. (Bristol.)
- £5 to the widow (81) of a registered chemist and druggist, who has had four previous grants amounting to £35. (Redhill.)
- £20 to a registered chemist and druggist (71) for eight years a subscriber, and formerly a local secretary. Suffering from failing sight and ill-health. (London.)
- £5 to a former associate and subscriber (40). Is in difficulties owing to his wife's ill-health. Had had three previous grants of like amount. (London.)
- £10 to a former associate (76), who has had three previous grants of a like amount. (Croydon.)
- £10 to the widow (71) of a registered chemist and druggist, who has had eight previous grants of £10 each. Is unable to earn anything. (Birmingham.)
- £10 to the widow (45) of a chemist and druggist member. Applicant had a grant of £10 in 1891, since when she has supported herself. She has two children (girls) to support. (Thornton Heath.)
- £10 for the benefit of the orphan children of a registered chemist and druggist who died in January last, and his wife soon afterwards. The eldest supports herself, and the two next, who have been ill, hope shortly to obtain situations. (Edinburgh.)
- £15 to a chemist and druggist member and subscriber who was in business for thirty-three years, but had to dispose of it in January last owing to ill-health, and now has no means. (Newport, Mon.)

One application was deferred for further information, and four others were not entertained.

The SECRETARY reported the death of Geo. Chestham, an annuitant, aged 82, on April 16.

The Vice-PRESIDENT, in moving the adoption of the report, said it was very satisfactory to find, as the President had said, that the subscriptions were coming in well, for it was quite evident from the present report that a good deal of money was re
quired, no less than a hundred guineas having been voted, subject to the approval of the Council, this month. It was not desirable generally to deal with the cases in detail, but he could not forbear mentioning one case from Scotland which was of a truly heartrending character. It was that of a family of eight persons living in Edinburgh who spent a happy Christmas together, and before last quarter-day four of them had been removed by death. The father came to Edinburgh about thirteen years ago, and he died in March last of consumption, probably brought on by the troubles he had undergone. Previously to that the eldest son, who had just come of age, died, after very great suffering. He had an accident when a boy, which resulted in hip disease, and that progressed until at the time of his death he had lost both legs and one of his arms. He died in January. In March the father died; a few days afterwards the youngest child was attacked with croup, was taken to the hospital, and died before her mother could be summoned, and three days afterwards the mother died also. In the meantime two other girls were taken with scarlet fever, and were removed to the infectious ward of a hospital, where, happily, the eldest sister was engaged as a nurse, and through her devotion and skill they were now, happily, convalescent. He need hardly say that this case excited a great deal of sympathy in Edinburgh, and no doubt assistance would be forthcoming; but it was very satisfactory to think that the Benevolent Fund was able to step in and give some immediate relief in such a distressing case. Even at the risk of being tiresome, he begged again to call attention to the case of Mary Margaret Lewis, who was a candidate for the Welsh Girls’ School. He had received an intimation that Alderman Vaughan Morgan had interested himself in the case, and also Mr. Octavius Morgan, late M.P. for Battersea, and many votes had been secured, so that he hoped those who had interested themselves in the case would be encouraged to go on.

Mr. Johnston said from personal knowledge he would like to say that their Vice-President had very correctly represented the facts of this sad case. For himself he felt proud that Scotland rarely applied to the Society for relief; but he was not less pleased that when a deserving case did come up it was met in the spirit shown on this occasion. He had no doubt friends would be found to do what was possible for those two orphans, and he trusted that what the Society had done would quicken their sympathies, and open the hearts as well as the pockets not simply of those outside the Society but also of their members.

Mr. Young said he should like to emphasise Mr. Johnston’s closing remark in view of their income being rather diminishing than increasing. Just now, he must admit, the prospects of business were not too rosy, and the present terrible competition they must expect, he feared, to become more intensified rather than the reverse. Persuading some of the many prospectuses with which one was now flooded he had noticed the absence of all provision in them of anything approaching superannuation to those who would grow old in the service. He feared therefore that they must expect with, as he had said, a diminishing income, even an increase of applications for grants, and he did therefore hope that many who were very well able to do so would contribute in large numbers and more liberally to this Fund.

The report and recommendations were unanimously adopted.

REPORT OF THE RESEARCH COMMITTEE.

This report was as follows:

“The Research Committee has held meetings once a month during the past year, at which the Director has made periodical reports on the work of the Research Laboratory.

“Mr. H. A. D. Jowett, B.Sc., Lond., has been appointed to succeed Mr. E. F. Harrison as Demonstrator, and Mr. Francis H. Carr has been elected Salters’ Research Fellow in Chemistry by the Court of the Salters’ Company.

“There has been a considerable increase in the number of applications for admission to the Laboratory during the past year. The total number of workers during the session has been fourteen, the highest number yet recorded, whilst at the present time there are eleven persons at work, so that every bench in the Laboratory is now occupied.

“Some of the workers are engaged in preliminary operations, others are occupied in special pharmacological and chemical enquiries.

“Considerable progress has been made in connection with the investigation of theaconite alkaloids, several new inquiries having been started.

“With the object of throwing further light on the new constitution for aconitine which resulted from the work of the laboratory last year, a number of derivatives of A. napellus have been prepared and their properties investigated, so that the constitution of aconitine and its relationship to the other alkaloids, which, up to the present, have been established by a very definite line of analytical evidence, may be substantiated by synthetical proof. So far, however, no very conclusive results have been obtained from these synthetical experiments, but they have led to the production of a number of new compounds, whose chemical properties and physiological action are of considerable interest.

“Simultaneously with this work the physiological action of the alkaloids—aconitine, benzoaconitine, pycraconitine, aconitine, and their derivatives—has been investigated by Professor Cash, F.R.S., with highly purified specimens specially prepared for the purpose.

“A long series of experiments has also been carried out in the hope of devising an accurate method of estimating aconitine in the presence of the other aconite alkaloids. Great difficulties have been encountered in this work, but it is hoped that eventually a satisfactory conclusion may be reached. Progress has also been made with the isolation and examination of the alkaloids contained in two other species of aconite, viz., Japanese aconite and the Aconitum heterophyllum of India, and in these cases also the physiological action of the pure substances will be determined.
"In connection with this work on the aconite alkaloids, the Committee wish to acknowledge the great assistance which has been rendered to the inquiry by the Royal Society through a grant from the Government Fund towards the expenses of the chemical and physiological experiments. Without this pecuniary assistance, which has now been rendered by the Royal Society during three successive years, it would not be possible to continue this costly investigation.

Several other enquiries, having chiefly physiological interest, have been conducted during the past year. At the suggestion of the Director of the Royal Gardens, Kew, an examination has been made of the active constituents of a medicinal plant growing in Trinidad—_Piper oceatum_. A crystalline substance named piperovatine has been obtained and its chemical properties described, whilst its physiological action has been investigated by Professor Cash. The similarity between the physiological action of this drug and that of the well-known pellitory of medicine led to an examination of this plant, with the result that a crystalline, highly active substance, closely resembling piperovatine, has been isolated.

At the suggestion of the Director of the Imperial Institute (Sir Frederick Abel), who kindly supplied the material, an investigation has been made of the constituents of _Podophyllum emodi_, which is abundant in India, and is regarded there as a possible medicinal substitute for the American _Podophyllum peltatum_, which is now so extensively employed. It is intended to isolate the constituents of both these drugs and to compare their chemical properties, and also their therapeutic effects. Progress has already been made with this work.

The increase in the number of workers has considerably augmented the expenses of the Laboratory.

The statement of the receipts and expenditure for the year shows a credit balance of £14 3s. 3d.

The results of the year's work have so far been published under the following titles:

- 'The Action of Iodine and of Methyl Iodide on Aconitine,' by Professor Dunstan and Mr. H. A. D. Jowett.
- 'Acetyl Derivatives of Aconitine and Benzoconine,' by Professor Dunstan and Mr. F. H. Carr.
- 'Aconitine Aurichlorides,' by Professor Dunstan and Mr. Jowett.
- 'The Constituents of _Piper oceatum_,' by Professor Dunstan and Mr. Henry Garnett.
- 'The Active Constituent of the Pellitory of Medicine,' by Professor Dunstan and Mr. Garnett.
- 'The Action of Methyl Iodide on Hydroxyamine,' by Professor Dunstan and Mr. Goulding.
- 'Formaldehyde,' by Professor Dunstan and Dr. Bossi.
- 'The Reduction Products of Nitro Compounds,' by Professor Dunstan and Mr. Dymond.
- "The expenses of the three last-named investiga-

tions have been defrayed by a grant from the Chemical Society.

- "M. Carthgie, President.
- "W. G. Cross, Vice-President.
- "T. Cross.
- "G. F. Schacht."
- "T. Lauder Brunton, Members of Council."
- "Charles Kin, Additional Members of the Committee.
- "E. Frankland.
- "M. Foster."
- "March 5, 1895."

The President formally moved that this report be received and entered on the minutes.

Mr. Martin said he must repeat what he said last year, that he deplored that the work of the Research Laboratory had so little bearing on medicine. There had been three further papers on aconitine, three on purely chemical subjects, which had but very slight bearing on medicine, and two only on subjects distinctly medical, viz., on substances sent for examination from the Royal Gardens at Kew and from the Imperial Institute. He was glad to see that this had been done, but with regard to the purely chemical papers he must emphasise what he said before. He did not object to any students obtaining any amount of kudos for what they did in the laboratory, on the contrary, the more they got in a legitimate way the better; but he did object to subjects being taken up for the mere sake of kudos. There were problems almost innumerable yet to be worked out in connection with medicine. Last year he referred to the subject of ipecacuahua, and an exceedingly good paper had been published upon it, not as the result of work in the Research Laboratory, but by private individuals—Dr. Paul and Mr. Cowley. The Research Laboratory might have taken this up at any time, and so with regard to ergot and many other drugs which required investigation. A new pharmacopoeia was on the eve of being published, but after seven years' work he feared the Research Laboratory would be able to contribute very little to its pages.

Mr. Martindale said the report, which was dated March 5, stated that there were eleven students; he understood that now there were ten, and that of those three or four were foreigners, and only six pharmaceutical chemists, for whom the laboratory was specially intended.

The President said he only knew of one foreigner, and no pharmaceutical chemist had been excluded to make room for an outsider. The foreign gentleman referred to was of very great assistance in the laboratory, and not the least so to pharmaceutical chemists who came there without any previous experience of research work. The Committee would be glad to see twelve pharmaceutical chemists there, and he might add that anyone from outside who came in for a short time to do special work paid the cost of materials used.

Mr. Bottles said the financial statement attached to the report was rather confusing, or at any rate was beyond his comprehension. It contained a statement that £400 had been granted by the Council and by the Royal Society, but when he referred to the financial statement of the Society he found £400 6s.
charged to the Research Laboratory. Then, again, there was a statement that the expense of certain investigations had been defrayed by a grant from the Chemical Society, but he saw no mention of such a grant in the financial statement. In February, 1891, there was a minute to the following effect:—"That the direction of the Research Laboratory shall constitute a part of the regular duty of the Professor of Chemistry, and that he shall have authority and receive instructions from the Council, and not, as hitherto, from the Committee, but it appears desirable that the general control of the laboratory should be, as at present, vested in the Research Committee." He certainly thought the question of allowing the Research Laboratory to be used for the purposes of the Chemical Society should have been brought before the Council, but he had no knowledge of it ever having been done.

Mr. Gostling said he agreed to a considerable extent with Mr. Martin, that the work done was not that which was required. It occurred to him that it would be far better if the resolution which Mr. Bottle had read were acted on, and a report presented to the Council each month from the Research Committee, so that they might know more of what was going on.

The President said in the financial statement of the Society the grant to the Research Laboratory and the Director's salary were put together; there was also an extra grant of £80 for a special purpose. The period covered by the two statements was not identical, which introduced another difficulty, and the grant from the Royal Society was paid direct to the Research Committee. With regard to the special chemical paper, a grant was made to Professor Dunstan by the Chemical Society, and he asked the Committee whether they would like the name of the Research Laboratory used in connection with it, and it was thought desirable that it should be so connected; otherwise Professor Dunstan would have carried out the investigation himself, as all professors were entitled to do when it did not interfere with their ordinary duties, and the result would have simply had his own name connected with it.

Mr. Martin asked if the Research Committee thought it consistent with its duty to place the laboratory at the disposal of anyone to conduct researches for another society without any control over it. He did not think that was the purpose for which the laboratory was equipped and endowed.

The President said the professor of chemistry in every institution was entitled to do work of his own, and this was a case of that sort. It was not done for the Chemical Society.

Mr. Storkar observed that in the Society's financial statement the Research Laboratory was put down for £400 in one sum without any details; could not the details be given?

The President said the £400 included the sum paid to the Director as salary, and also the £150 grant and the £50 special grant. It was not desirable to go too much into detail in a financial statement. This was prepared and approved by the Finance Committee.

Mr. Bottle asked if there had been any further grant from the Royal Society. It was currently reported that argon was being investigated in the Research Laboratory, and he should like to know if this were a fact.

The President said he had not heard of it. The motion was then put and carried unanimously.

The Library, Museum, School, and House Committee.

Library.

The report of the Librarian had been received, and included the following particulars:

<table>
<thead>
<tr>
<th>Attendance</th>
<th>Total</th>
<th>Highest</th>
<th>Lowest</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td>March</td>
<td>Day</td>
<td>536</td>

<td>Country</td>
</tr>
<tr>
<td>March</td>
<td></td>
<td>189</td>
<td>108</td>
<td>81</td>
</tr>
</tbody>
</table>

Donations to the Library had been announced (Pharm. Journ., April 6, p. 874), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended the purchase of the undermentioned book for the Library in London:—Benedikt and Lewkowitz, Chemical Analysis of Oils, Fats, and Waxes, 1895.

Museum.

The report of the Curator had been received, and included the following particulars:

<table>
<thead>
<tr>
<th>Attendance</th>
<th>Total</th>
<th>Highest</th>
<th>Lowest</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td>March</td>

<td>7</td>
<td>1</td>
</tr>
</tbody>
</table>

Donations to the Museum had been received (Pharm. Journ., April 6, p. 874), and the Committee had recommended that the usual letters of thanks be sent to the respective donors.

The President, in proposing the adoption of the report, said it contained nothing special to which he need direct attention, and it was thereupon put and carried.

Investment of Funds.

The President said several "parcels" of ground rents were now in view, and he proposed, as there was no existing committee to deal with the subject, that the President, the Vice-President, the Treasurer, and Mr. Hills, with the assistance of Mr. Butt, should be appointed a Freehold Investments Committee, with power to take all necessary steps to purchase suitable ground rents when opportunity occurred.

This was at once agreed to.

A "Soothing Syrup" Fatality.

The President said a communication had been received from the Privy Council, enclosing a copy of a letter addressed to the Home Office by Mr. Hulme, coroner, of Worcester, with reference to a death, found by a jury to have resulted from the taking of "Mrs. Winslow's Soothing Syrup." The inquest was held on a boy thirteen months old, and the evidence was to the effect that two doses, one of a teaspoonful and the other of half a teaspoonful, of Mrs. Winslow's Soothing Syrup were given to the deceased, and that he died from the effects of the morphine contained in
such syrup. The advertisement on the syrup stated that it contained only one-eighth of a grain of morphine to the fluid ounce, but the analysis made by Mr. Roos, the public analyst for Northampton, disclosed that it contained one grain to the fluid ounce. The jury, in their verdict of death from morphine poisoning, added that, in their opinion, the sale of preparations containing so dangerous a drug as morphine was most strongly to be condemned, and ought not to be allowed except under proper restrictions. The letter had been acknowledged by the Secretary, and the coroner would, through the Home Office, be informed that the provisions of the Pharmacy Act applied to such preparations.

ACKNOWLEDGMENT BY A CORRESPONDING MEMBER.

The President read a letter from one of the Society's corresponding members, Mr. Rudolf Kobert, of Dorpat, forwarding as a slight acknowledgment of his election as corresponding member the 11th and 12th parts of the "Arbeiten des Pharmakologischen Institutes zu Dorpat."

COMPULSORY EARLY CLOSING.

The President next read a letter from the home sec. of the Plymouth, Devonport, Stonehouse, and District Chemists' Association, enclosing a resolution passed at a quarterly meeting, approving of chemists being included in Sir J. Lubbock's Compulsory Early Closing Bill, provided a clause be inserted allowing medicines to be dispensed in cases of emergency. Perhaps this letter had better be referred to the Parliamentary Committee.

Mr. Hampson said he did not object to the reference, but he would take the opportunity of strongly protesting against this kind of legislation and interference with the business of people. Their trade was, of course, out of the ordinary grooves. For his part he saw no reason for the State interfering and telling them when they should shut and when open their shops.

The President said he would remind the Council that when this subject was last formally before them he was instructed to oppose the Bill so far as chemists and druggists were concerned. The opposition, he had reason to know, was not confined to themselves, and perhaps he might hope that an outcome of it would be an amending clause.

The letter was referred accordingly.

PRELIMINARY EXAMINATIONS.

The President said a letter had been received from the Registrar of the Pharmaceutical Society of Ireland asking this Council to accept the preliminary examination of that Society in lieu of the preliminary here, and enclosing a syllabus showing that practically the Irish examination embraced all the subjects included in the English.

On the suggestion of the President it was resolved to refer the communication to the Board of Examiners for consideration and report.

REPORT OF EXAMINATIONS.

April 13, 1895.

Scotland.

| Examined | 3     | 121   | 124   |
| Passed   | 8     | 52    | 55    |
| Failed   | 0     | 69    | 69    |

First Examination.

| Examined | 394   |
| Passed   | 189   |
| Failed   | 205   |

Thirty Certificates were received in lieu of the Society's examination.

The above report having been presented, Mr. Atkins said he was much struck by the figures; it seemed as if the proportion of failures was increasing.

Mr. Young thought if the stringency of the Preliminary examination were increased it would have a beneficial effect on the Minor.

The President said it would be seen that Dr. Stevenson referred to that in his report; but he did not lay so much stress on increased stringency as on the Preliminary being passed at the proper time. Men prepared for the Preliminary and passed at the age of, say, 23 or so were no good. That was the real root of the difficulty. No doubt the examination ought to cover a wide area, and to represent more completely than it did what might be called an ordinary school training. But even as it was it would be a material benefit if it were passed at the right time. He thought a little algebra and geometry almost essential, and for himself should be glad if the Society could get rid of the first examination altogether, and rely entirely on certificates, to be granted by ordinary examining bodies.

Mr. Atkins said he hoped the matter would receive further attention. It was an ancient story, but worth repeating, that years ago some of them urged the importance of insisting that the Preliminary examination, or its equivalent, should be passed before apprenticeship. It had been said there were practical difficulties in the way. He did not know what they were, but he was certain many entered on the business thoroughly unprepared. He was sorry to say that the old method of apprenticeship was rapidly disappearing. He could recollect when apprenticeship involved a large responsibility on the part of the master, and he deeply regretted being impressed with the conviction that the old conditions had disappeared. Now it was merely a question of pupilage out of the house, and simply having the run of the place. The result was that they no longer had the style of man they once got. They might have a higher scientific training, but they did not get the training at the counter which was imparted under the old system.
Mr. Allen agreed with Mr. Atkins. He took a great interest in this question, and had done so since he was an apprentice himself. He was satisfied that most of the failures were owing to the lack of preliminary training. Men in business should make it a sine qua non with every apprentice that he should have passed the Preliminary examination, for without that he was not in a position to take advantage of the technical instruction his master could give him.

Mr. Grose suggested that the difficulty would be got over to a great extent by requiring the Preliminary examination to be passed at least three years before the candidate presented himself for the first portion of the Minor. Many men now occupied their leisure time during their apprenticeship in preparing for the Preliminary, and having passed that in the autumn presented themselves for the Minor in the early part of the next year.

The President said Mr. Grose had probably forgotten that a clause had been included in several draft Bills providing for the division of the Minor examination. It was held at present that the Preliminary examination was a part of the Minor, and though an interval of three months had been imposed between the Preliminary and the Minor it was not considered possible to go any farther at present.

The Vice-President said he was very glad to hear what had been said about the passing of the Preliminary before apprenticeship, and he was glad to say that schoolmasters were becoming aware of the necessity of that course being followed, and were in the habit of asking their pupils what their future course would be, and if they were going to be chemists, of suggesting that they should pass the Preliminary examination immediately on leaving school. He hoped therefore that in the future there would be an improvement.

DIVISIONAL SECRETARY.

The President said he had to report with much regret the rather sudden death of Mr. Fitch, Divisional Secretary for Hackney. He was a man of considerable capacity, and at the various meetings of Divisional Secretaries no one had given more assistance to the general discussion than Mr. Fitch. He moved the election in his place of Mr. Nichols, 99, Wick-road, South Hackney.

The proposition was at once agreed to.

GENERAL PURPOSES COMMITTEE.

The portion of the report of this Committee dealing with the school prize examinations having been read, the President moved that upon it the following awards be made:

**Practical Chemistry.**
- Bronze Medal: Francis F. A. Tunbridge.

**Chemistry and Physics.**
- Bronze Medal: Francis F. A. Tunbridge.

**Botany.**
- Bronze Medal: Harold Brown.

**Materia Medica.**
- Bronze Medal: Harold Brown.

**Pharmacy and Practical Pharmacy.**
- Bronze Medal: John Robert Walker.

The proposition was unanimously agreed to.

RESEARCH COMMITTEE.

The Council having gone into committee to consider the subject of the Research Laboratory, as the result of the discussion it was resolved, on the motion of Mr. Harrison, seconded by Mr. Storrar, "That it is desirable the subject of the Research Laboratory be fully considered at an early date by the incoming Council of the Society."

ANNUAL REPORT.

A draft of the annual report was adopted and ordered to be published in the Pharmaceutical Journal (see page 995).

LEGAL PROCEEDINGS.

The legal portion of the report of the General Purposes Committee was considered in committee, and, on resuming, the report and resolutions were unanimously adopted, and special resolutions were passed authorising the Registrar to take proceedings against the persons named in the report.

Proceedings of Societies in London.

CHEMICAL SOCIETY.

A meeting was held on Thursday, May 2, 1895, the President, A. Vernon Harcourt, F.R.S. in the chair.

The following papers were read:

At the commencement of an investigation undertaken on the action of sulphuric acid on naphthalene and its derivatives, and the properties and reactions of certain isomers, it was found that the state of our knowledge concerning the di- and tri-chloro-naphthalenes was both incomplete and in many cases unreliable. An investigation was then undertaken of the di- and tri-chloro-naphthalenes, and in 1890 an account was given of the whole series of ten di-chloro-naphthalenes, and since then the corresponding complete series of fourteen tri-chloro-naphthalenes have been prepared, and their physical properties and reactions studied, and specimens of both complete series were exhibited at the meeting.

If Erlenmeyer's formula for naphthalene be correct, then there should be ten isomeric di-chloro-naphthalenes where the halogen takes up various positions as 1, 2; 1, 3; etc., and also fourteen isomeric tri-chloro-naphthalenes, such as 1, 2, 3: 1, 2, 4; etc.
This exact number of isomers has been obtained, and all attempts to increase the number failed, thus affording very strong proof of the correctness of Erlenmeyer’s formula.

Dealing first with the di-chloro-naphthalenes, it was found that if all the derivatives previously described were different isomers, then twelve di-chloro-naphthalenes were known, and hence it was necessary to repeat the work of previous observers in order to find out whether or not the number must be reduced. The di-chloro-naphthalenes were first studied by Erdmann, who used the following method of preparation:—From a chlor-toluene of known constitution the corresponding chlor-benzaldehyde was produced by oxidising the methyl group to the aldehyde group (CHO). The chloro-benzaldehyde was then converted into the corresponding phenyl-isocrotic acid or lactone by Perkin’s synthesis of treatment with succinic acid in presence of potassium acetate, and the lactone thus obtained by heating loses water and suffers condensation, yielding a naphthol. The hydroxyl group is then replaced by chlorine, either by treatment with phosphorus pentachloride, or diazotisation. Taking the case of 1,4-chlor-benzaldehyde, the following equations represent the formation of the corresponding di-chloro-naphthol:

\[
\begin{align*}
(1.) & \quad C_6H_4Cl.CH_2O_2 = C_6H_4Cl.CH_2O + H_2O \\
& \quad (\text{Para-chlor-toluene}) \quad (\text{Para-chlor-benzaldehyde}) \\
(2.) & \quad C_6H_4Cl.CH_2CHO + \text{HCCH} = \\
& \quad \text{(Succino acid)} \\
& \quad \text{C}_6\text{H}_4\text{Cl.CH} \quad \text{C.CH}_2\text{COOH} \quad + \text{H}_2\text{O} \\
(4.) & \quad \text{C}_6\text{H}_4\text{Cl.CH} \quad \text{C.CH}_2\text{COOH} \quad \text{CO}_2 \\
(5.) & \quad \text{C}_6\text{H}_4\text{Cl.CH} \quad \text{C.CH}_2\text{COOH} \quad \text{H}_2\text{O} \\
(6.) & \quad \text{C}_6\text{H}_4\text{Cl.CH} \quad \text{C.CH}_2\text{COOH} \quad \text{H}_2\text{O} \\
(7.) & \quad \text{C}_6\text{H}_4\text{Cl.CH} \quad \text{C.CH}_2\text{COOH} \quad \text{H}_2\text{O} \\
(8.) & \quad \text{C}_6\text{H}_4\text{Cl.CH} \quad \text{C.CH}_2\text{COOH} \quad \text{H}_2\text{O} \\
\end{align*}
\]

Erdmann prepared several isomers by this method, and relied on the method of formation as proof of the position of the halogens. It is possible, however, that during these reactions an intra-molecular change occurs, and thus the proof of the position of the halogens in di-chloro-naphthalene is incomplete. The authors used different methods for their proofs, such as the formation of tri-chloro-derivatives by sulphonation and subsequent chlorination, a method similar to that employed by Baeyer in his investigations on the haloid derivatives of benzene. In this way the ten isomers of di-chloro-naphthalene were identified.

Up to 1885 most of the work done on tri-chloronaphthalene had been done by Aléné, Atterberg, Cleve, and other Swedish chemists, and several different isomers had been prepared and described, but very little was known as to the position of the haloid groups in the molecule. In 1890 the authors added five new isomers to those already described, but at the same time showed that two isomers previously described were identical, thus leaving only one isomer out of the fourteen possible isomers to be prepared.

The tri-chloro-derivatives were prepared by several different methods, and in most cases the position of the chlorine atoms in the molecule was determined by two or more independent methods, so that no doubt was left regarding the position of the haloid groups in the different isomers.

In some cases the di-chloro-naphthalene of known constitution was sulphonated by treatment with sulphuric acid, and the resulting chloro-sulphonic acid chlorinated by treatment with phosphorus pentachloride, or a naphthylamine sulphonic acid of known constitution was used as a starting point, and the groups replaced by chlorine by general methods.

The missing 1, 2, 3 tri-chloro-naphthalene (see formula above) was prepared by Erdmann’s method from di-chloro-benzaldehyde (ClClCHO = 1,2,5). Thus the whole series of fourteen isomers were prepared, their physical properties as M.P., crystalline form, etc., examined, as well as their behaviour on sulphonation.

In 1890, however, Cleve also prepared the missing 1, 2, 3, isomer by nitrating the chloro-naphthalene sulpho-chloride (C6H5ClSO2Cl) and then distilling the product with phosphorus pentachloride, and obtained a body of different M.P. to that described by the authors. The question of this apparent discrepancy was investigated by the authors, who found that Cleve’s method of preparation as a proof of the position of the haloid groups was unreliable. When the nitro-chlor-naphthalene sulpho-chloride [C6H5Cl(NO)(SO2Cl)2] is distilled with phosphorus pentachloride, an intramolecular change takes place. If, however, the nitro (NO2) group be first reduced to amino (NH2) and then the substance distilled with phosphorus pentachloride, a derivative is obtained identical with that obtained by the authors.

In the case of distillation of the sulpho-chloride and apparent replacement of (SO4Cl) group by chlorine by means of phosphorus pentachloride, it is probable that this is not a case of displacement but of simple loss of sulphur dioxide (SO2), the chlorine atom in the tri-chloro-naphthalene obtained being not derived from phosphorus pentachloride, but from the (SO4Cl) group. It is found that heating alone brings about this change, so that phosphorus pentachloride merely acts as a catalytic agent.

In several isomers cases of dimorphism occur—compounds are obtained differing only in melting point, crystalline form—and this property was found to be generally associated with isomers having the chlorine atoms, in the position 2, 5. The formation of these di-chlor-naphthalenes and tri-chlor-naphthalenes thus affords almost conclusive evidence of the correctness of the formula proposed by Erlenmeyer, and the later one proposed by Claus must therefore be abandoned.
THE SOLUBILITIES OF GASES IN WATER UNDER VARYING PRESSURES.

BY R. P. PERMAN, D.SC.

The methods used for determining the absorption coefficient of various gases have been of two types.

(1.) Bunsen’s method depending on the measurement of diminution of volume of the given gas after shaking with a known volume of the solvent.

(2.) Hufner’s method consisting in the preparation of a saturated solution of the gas, and then pumping out the gas from solution and measuring it.

The apparatus used by the author dependent on aspiration by a current of air through a saturated solution of the gas and measurement of the gas removed at definite intervals of time.

A saturated solution of the gas was placed in a flask kept at a constant temperature, and through this a current of moist air aspirated at a regular rate, and the quantity of gas removed determined at definite intervals. The results were tabulated as a curve with the quantity of gas removed and the time of aspiration as co-ordinates; from this curve a new curve was deduced with pressure and concentration as co-ordinates.

Now, if the law of Henry for solubility of gases at different pressures holds good, the pressure-concentration curve will be a straight line, if not, it will be a curve. The quantity-time curve is logarithmic and is always curved. Experimenting in this way, it was found that solutions of ammonia, sulphur di-oxide and hydrogen chloride in water do not obey Henry’s law, but chlorine, bromine, carbonic anhydride, and hydrogen sulphide obey Henry’s law, these results thus confirming those previously obtained by other observers.

THE EXISTENCE OF HYDRATES AND OF DOUBLE COMPOUNDS IN SOLUTION.

BY R. P. PERMAN, D.SC.

The author endeavoured to apply the method above described to determine whether salte exist as hydrates in solution. If a crystalline salt as sodium sulphate exists in solution as a hydrate (Pickering), there would be no change in concentration on solution, but if these hydrates do not exist and solution be due to dissociation (Arrhenius), then the addition of this salt would cause a difference in the concentration. If a gas be dissolved in such a solution, the quantity dissolved will depend—ceteris paribus—on the amount of water present. It was found that on dissolving crystalline sodium sulphate no such change occurred, thus supporting the hydrate theory of solution. When anhydrous sodium sulphate was dissolved a difference in the concentration was shown by the curve of pressure-concentration, proving that the anhydrous salt forms a hydrate and thus alters the concentration.

The following paper was taken as read: “Note on the Formation of Platinic Pyrophosphate,” by R. E. Barnett.

CHEMISTS’ ASSISTANTS’ ASSOCIATION.

The annual general meeting of this Association was held on Thursday, May 2, the President, Mr. R. H. Jones, in the chair.

After the minutes of the previous meeting had been read and confirmed, Messrs. Chaston and Dyson were appointed scrutineers of the voting papers for the Council of the session 1895-96, and Messrs. A. J. Bellamy and W. G. Crouch to audit the balance-sheet.

Whilst this business was being transacted, the President announced that arrangements had again been made for a series of Sunday excursions during the summer months, the first being fixed for the 12th inst., Dorking being the destination. With reference to the prizes offered by the Association and Burroughs, Wellcome and Co., he regretted that the Council were unable to make any award in either instance. He then called upon Mr. C. Morley to read

THE ANNUAL REPORT.

In this the Council congratulated the members upon the highly successful session which was now at its close. During the past year 16 new members had been elected, making the present number 148, whilst the number of patrons was 48, the same as at the close of last session. During the year sixteen papers on scientific and trade matters had been read and discussed at the evening meetings, and in addition two discussions on topics of direct trade interest had been held. Several musical and social evenings had also proved great attractions. The conversations, for the conspicuous success of which they were greatly indebted to the Vice-President, Mr. H. H. Robbins, was held last November, and an innovation in the shape of a smoking connoisseur at the Horse Shoe Hotel had more than justified their expectations. Allusion was made to the fact that the work sent in by competitors for the essay prize and the prize for practical work did not justify an award in either instance. The attendance both at the evening meetings and at the annual dinner, which was again held at Cannon Street Hotel in March, Mr. Walter Hills occupying the chair, had been extremely satisfactory. The financial position of the Association was exceptionally good, and the proceeds of the sale of programmes at the smoking concert and social evenings had been handed over to the Benevolent Fund of the Pharmaceutical Society.

In moving the adoption of the report the President commented briefly upon its gratifying nature, and stated that the decision of the Council with respect to the non-award of the prizes had been arrived at after careful deliberation, and they were of opinion that the competitors had not done themselves justice. He expressed the hope that in the next session work would be produced which would be worthy of the essayists and the Association itself. Mr. H. H. Robbins having briefly seconded the motion, it was carried unanimously.

The balance-sheet was then read by Mr. C. J. Strother, Hon.-Treasurer. He expressed his great satisfaction in having to announce a balance of
£67 19s. 7d., as against £38 7s. 11d. last year, this being the largest that had been declared since the formation of the Association. The President in moving the adoption of the balance-sheet, acknowledged the indebtedness of the Association to their financial secretary, Mr. E. W. Hill, for their flourishing position, as it was through his instrumentality that the rent of the rooms had been considerably reduced. In addition, the donations had been considerably in excess of past years, and arrangements had been made by which the sum received for the publication of reports was much larger than last year. Mr. Hill seconded the motion, and it was unanimously adopted.

The scrutineers now handed in their reports on the Council voting papers. Seventeen members had been nominated, of whom fourteen were elected. Fifty-five voting papers had been received, all of which were valid. The candidates received the undermentioned number of votes:—R. H. Jones, 53; E. W. Hill, 51; C. Morley, 51; R. G. Guyer, 49; R. Melulah, 49; C. J. Strother, 48; E. Unney, 48; W. Moore, 47; H. H. Robbins, 45; W. R. Roberts, 45; A. Gunn, 39; G. Roe, 37; W. G. Crouch, 32; T. M. Taylor, 32. The votes for the unsuccessful candidates were:—T. Tickle, 29; W. Anderson, 26; T. A. Elwood, 21.

The President then read his Valedictory Address.

In the course of his remarks he stated that the Association could look back with particular satisfaction on the work of the past session, inasmuch as the vexed question of Sunday excursions a year ago threatened to do serious injury to its stability. He was glad to say that the split, which had caused several members to sever their connection, had not affected the well-being of the Association, in fact it was at the present time on an unprecedentedly satisfactory basis.

He had a few suggestions to make on taking leave of the Association in his presidential capacity, which were partly his own and had partly arisen from discussions with other members. It was important that four additional evenings during the ensuing session should be devoted to social gatherings. On one occasion a smoking concert might be held, and on the other three Cinderella dances should be organised. He did not doubt these would all prove exceedingly popular, and attract a considerable number to join the Association. As matters at present stood, it was practically impossible to get sufficient good men from their own ranks to read papers which embodied really first-class work before the Association, and it was necessary on some occasions to go outside, as they had done in the past session with conspicuous success. He alluded to the extreme difficulty experienced in getting members to contribute on the evenings devoted to short papers, and to counteract this he suggested the publication of a blue list, drawn up in unpretentious fashion, which would encourage members to bring forward subjects of interest. He hoped to see the strictly scientific work of the Association much improved during coming sessions, and was of opinion that if modifications were introduced on the lines he had suggested the Association would present advantages to its members of an entirely exceptional character.

On vacating the chair he wished to express his indebtedness to the two honorary secretaries, Messrs. Hill and Morley, who had thrown themselves heart and soul into the work of the Association, and had much lightened his own work, and also to Mr. Robbins for the great assistance he had rendered in carrying out their social arrangements.

At the conclusion Mr. Hill proposed and Mr. Strother seconded a very hearty vote of thanks to Mr. Jones for the courteous and dignified manner in which he had filled the chair during the past session. This was carried with acclamation, and Mr. Jones having briefly responded, the proceedings terminated.

Scottish Transactions.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

The annual business meeting of the seventeenth session was held in the Pharmaceutical Society's Hall, 36, York Place, Edinburgh, on Friday, May 3, at 9.15 p.m., Mr. Alexander Sutherland, President, in the chair.

The minutes of last meeting were read and approved.

The Secretary read the report of the Prize Committee on the "Ewing" Pharmacy Prize Competition, and in the unavoidable absence of Mr. Ewing, the President presented the prizes as follows:—Ewing Pharmacy Prize to William Makepeace Lock, 20, Queen'sferry Street (Cooke's 'Anatomy,' Craig's 'Materia Medica,' and Huxley and Martin's 'Practical Biology'); and Mr. Atken's Prize to John Robert Thompson, 48, Haymarket Terrace (Vines' 'Botany,' Geddes' 'Modern Botany,' and Thomson's 'Animal Life')

The following communications were then read:—

ERGOT OF RYE.

BY J. HARRIS BURNS.

The author gave an interesting description of the structure and life-history of the ergot fungus, his remarks being illustrated by a series of well-executed diagrams.

The next communication was on:—

FERRUM REDACTUM IN PILLS.

BY W. F. HAY.

The author gave his experience of a number of pill masses containing reduced iron and extract of cascara. The pills had been silvered, and after a few hours began to swell, and the silver coating cracked. The addition of glycerin to such masses markedly increased the tendency to crack. The
same difficulty was met with in a pill mass containing extract of logwood and reduced iron, when a small quantity of glycerin was used to make a mass. Also in the case of pills containing arsenious acid and reduced iron masses with glycerin of tragacanth. He found that extract of gentian and reduced iron made a pill which kept well, and he suggested that this excipient should be used in all such cases.

The reading of the papers was followed by a discussion, taken part in by Messrs. Burne, Hay, Hill, Sinclair, and Sutherland, and on the motion of the Chairman, votes of thanks were awarded to the authors.

The Secretary and Treasurer then read the annual report and financial statement, which were approved of. The former showed an increased membership, and the latter a balance of £1 2s. 11d. A sum of £1 1s. was voted to the Benevolent Fund of the Pharmaceutical Society.

The following office bearers were elected for the ensuing year:—President, Alexander Sutherland; Vice-President, J. Macintosh Cameron; Secretary, George Sinclair; Assistant-Secretary, J. Harris Burns; Treasurer, Alexander Murray; and as Members of Committee, Messrs. Cowie, Dey, Guthrie, Hay, McBain, Swanson, Thompson, and Thwaites. Messrs. Cowie, Dey, and McEwan were re-elected members of the Prize Committee.

The arrangements for summer botanical excursions and a suggestion as to holding summer meetings of the Association having been remitted to the Committee, the meeting closed with a hearty vote of thanks to the retiring office bearers.

**Correspondence.**

[Letters should be written as concisely as possible, on one side of the paper only, and preferably with name and address for publication.]

**The Major Examination.**

Sir,—If not too late I should like to answer the letter of Mr. Herbert Dyson in your issue of April 15. The chief point in his letter seems to be that the Major examination would be "disintegrated and degraded into a paltry system of piece-meal cram" if the suggestions of "M.F.C.S." were carried out. I ask Mr. Dyson whether he has any knowledge of the schools of pharmacy and the systems of cram in vogue to-day for passing the Major. I contend that there is little besides cram now. I speak from personal knowledge of students, both past and present, in at least three schools of pharmacy. The principals are not to blame. Many of them are men of considerable knowledge. They have not time to impart this knowledge under present conditions, so that their pupils can assimilate and retain it. The knowledge must be crammed in within a given time, no matter what the student's capacity may be. Add to this the fact that genuine students are strongly tempted to adopt this system of cram in order to pass, and I think we may consider the "disintegration and degradation" of the Major in a fair way to become an accomplished fact, if not already such. I have just received the last edition of Vine's 'Botany,' and will put my case in the form of a question to Mr. Dyson: Which man is the more likely to have a thorough groundwork in botany, the one who has spent six months in systematic and practical study of this book to the exclusion of other subjects, or the man who has devoted a year at one of our schools to the four subjects required for the Major? I agree with Mr. Dyson in deprecating a "modified Major." Along the lines suggested by "M.F.C.S." we are more likely to get an advanced Major or an "honours" division. What I deplore most of all is the killing of the student spirit in the majority of men by the present cram system. Time is required to rouse in men a real and lifelong interest in the subjects they have to study. What do we see everywhere but Major and Minor men losing all interest but that of £ a. d. as soon as they have passed! I could say much more, but I am afraid this letter is already too long.

**Another Associate in Business.**

**A Correction.**

Sir,—At the Executive meeting in Edinburgh on April 19 (Ph. J. [3], xxv., p. 948) I stated from memory, in reply to Mr. Sutherland, that a notice appeared in a recent Chemist and Druggist diary to the effect that the Inland Revenue authorities would not interfere when methylated spirit was supplied by medical orders on Sundays. I find the notice I had in mind appeared in the British Medical Journal, April 23, 1898, p. 886. It was in the following terms, in reply to an inquiry by Dr. Taylor, of Richmond:—

"Sir,—In reply to your letter dated the 23rd ultimo, I am directed by the Board of Inland Revenue to acquaint you that they have no power to allow the sale of methylated spirits on Sundays.

"I am, however, to add that, in so exceptional a case as that referred to by you, the Board would not be disposed to take any notice of an infraction of the law.—I am, Sir, your obedient servant,

"W. B. Herbert, Assistant-Secretary."

I shall be obliged by your inserting this correction.

Edinburgh.

JAMES L. EWING.

**The Council Election.**

Sir,—I am afraid members of the Society take but little interest in the annual election of the Council, for the reason that so little is known of the opinion of the gentlemen seeking election, or of their ability to make those opinions felt. Still, everyone must admit that it is desirable to place gentlemen on the Council who will not beegraded giving up their time in attending its deliberations, and who have the interests of the retail trade at heart. Among so many good names it is difficult to say which should be left out, but I would recommend to my fellow-electors that of those seeking election, who are not on the present Council, they should vote for the four gentlemen who reside within easy distance of town, or are actually resident there, and to erase from the list the names of existing members who have attended fewest meetings.

Reading.

CHAS. BRADLEY.

"* Our correspondent specified certain names in his letter, but for obvious reasons these names are suppressed. [Ph. J., Pharm. Journ.]"
Notes and News.

CONFLICTING EVIDENCE OF ANALYTICAL CHEMISTS. — During the hearing of a summons against Richard Towers for selling adulterated ginger, heard on May 2 at Lancaster, Dr. Estcourt, county analyst, certified that the sample contained 25 per cent. spent ginger. Drs. Campbell Brown and Williams, Liverpool, certified that the sample, which was supplied by Messrs. Wright, Crossley, and Co., of Liverpool, was absolutely free from adulteration, had no trace of spent ginger, and that anyone who knew ginger could not pretend the sample was other than high-class ginger. The magistrates adjourned the case for a Somerset House analysis.

SOCIETY OF CHEMICAL INDUSTRY. — The Liverpool section of this Society held its last meeting for the present session at University College, on May 2. Dr. C. A. Kohn gave a demonstration on the properties and laboratory of nickel carbonyl, the interesting compound of nickel with carbonic oxide which was described some time ago by Mr. Ludwig Mond. A paper was then read by Dr. Hurter on the “Efficiency of Electrolytic Apparatus,” and evoked considerable comment and a full discussion on the question of electrolysis. The sittings of the section are now suspended until November, when they will be resumed under the chairmanship of Dr. Gustaf Schack-Somer.

ORIGIN OF THE WORD "ARSENIC." — A later correspondent of the Academy, referring to the former communication on this subject (ante, p. 985), says that he was much struck by the writer’s opinion that “Dioscorides found in some Eastern language a word meaning arsenic (or rather orpiment), with some sort of resemblance to arsenic, and transmuted the word into this thoroughly Greek form”; and also that “ovdpden and ovdpned have both been taken from the same Oriental word.” He points out, in turn, that in Chinese the term liung hwang (literally “male yellow”) — red sulphur of arsenic or realgar; while t’ia hwang (literally “female yellow”) — yellow sulphur of arsenic or orpiment. These are the only instances, with which he is acquainted of minerals differentiated in Chinese by gender.

APPOINTMENT FOR PROFESSOR FREUND. — It is stated that Professor Freund, who is one of the chief authorities on the chemistry of alkaloids, and has for some time past acted as privat-dozent at Berlin University, has been asked to take charge of the chemical laboratory in connection with the Physical Institute at Frankfort-on-Maine.

GOLD IN THE SEA. — The Birmingham Gazette thinks it is some satisfaction to know that when the supply of gold ceases on land, it may be sought for in water. A chemist is alleged to have made the important discovery that in each ton of sea water a quantity of gold exists, and this suggests that there are great mines in the bed of the sea. An analyst who has “seriously investigated this matter” is also stated to be of opinion that about ten million tons of gold are distributed in the oceans, so that as we only get about two hundred tons every year from the mines on the dry land, “it is time that a company was formed to work the gigantic reefs beneath the sea.” This paragraph has duly gone the round of all similar sensational pseudo-news, but the question of the cost of recovery does not seem to have received the attention it merits.

OPENING OF THE SCHORLEMMER LABORATORY. — The Schorlemmer Memorial Laboratory at Owens College, Manchester, the first laboratory exclusively devoted to the study of organic chemistry in England, was formally opened by Dr. Ludwig Mond, on May 3 (see page 1020). The building provides much needed accommodation for the study of organic chemistry, and also includes a large laboratory for medical students, and a room for the preparation and storage of reagents. The total cost of the new building is stated to be £4800.

CHEMISTS’ CO-OPERATIVE SOCIETY. — The Saturday Review, commenting on the prospectus of this limited liability company, says this is a net skilfully woven on a great scale and cunningly provided with large and small meshes in order, if possible, to catch all sorts of fish. The small investor who timidly looks for good security is cheered with preference shares that are to pay a cumulative dividend of 7 per cent. per annum; the bold man who is not afraid to take a risk, is told of ordinary shares with a dividend of upwards of 16 per cent. per annum, a result which, the directors point out, “is, as regards the businesses purchased, founded on actual past trading experience.” The scheme is said to be difficult to characterise. To-Day points out the fallacy of the reasoning in the Financial Times article (ante, p. 988), and observes that the members of the Board are all very worthy gentlemen, but it has yet to learn that any one of them knows much about drugs, unless it be Dr. Clark, “who in distant days may have written prescriptions.”

THE SALE OF SECRET REMEDIES. — The Patent Medicine Journal thinks that the breaking up of the patent medicines trade would be a blow to thousands, besides the maker. How, it is asked, can ordinary people afford to buy the preparations of doctors and chemists? “If the latter are allowed to become monopolists matters will not be improved in that respect. There are many popular and wholesome remedies now obtainable at low prices, and if they should be swept into the monopolist net and inferior articles substituted for them, the many victims concerned may be trusted to kick — when it will be too late.” Perhaps, it is suggested, the new monopolists would better the articles and reduce prices to meet their susceptibilities! The argument of our contemporary is somewhat mixed, but in view of the increasing active opposition of the medical profession to the use of secret remedies, due allowance must be made for wounded feelings. At the same time the suggestions quoted are hardly quite fair.
REVISION OF THE B.P.—The Therapeutic Committee of the British Medical Association has drawn up a list of drugs of doubtful value, and is circulating the same amongst the members of the Association, with a view to ascertaining the relative frequency of the employment of certain drugs and preparations at present official in the British Pharmacopoeia.

THE SIZE OF DROPS.—At a meeting of the Royal Society of Edinburgh on Monday last, a communication was read “On Drops,” by Mr. J. B. Hanney, who appears to have obtained experimental verification of Tait’s conclusion arrived at some years ago. Thus, the size of the drop does not depend upon the weight of the liquid, but is proportional to the diameter of the delivery tube, whilst its separation is regulated by surface tension rather than by cohesion. In the experiments, the disturbing element of viscosity was got rid of by causing a given liquid to drop into another of different specific gravity. The separated particles of water, for example, were allowed to rise upwards in oil. It was further ascertained that when water was dropped in an atmosphere of benzene vapour the drops formed were much smaller than when the surrounding medium was ordinary air.

NUSSBAUM POISONING.—Cases of poisoning by nutmegs are somewhat rarely recorded in detail. An instance has occurred in America (Amer. Med. Surg. Bull.), Dr. Hodgson relating the case of a woman who was poisoned by eating two nutmegs at night and the same quantity next morning. When he saw the patient the following afternoon the pulse was 120, pupils dilated and non-contractile to light, patient drowsy and in pain in umbilical region. Strong tea and tablets of digitalis, strophanthus, belladonna, and nitro-glycerin were given, also 1 grain of caffeine citrate every hour or two. Next morning the pulse was 80, pupils contracted, temperature rose 1°, and urine loaded with phosphates. On the fourth day there was sweating, confined to the lower extremities, which, with the mydriasis, formed the most interesting feature in the case.

APOLOGIA PRO ELECTRICITATE SVA.—Under this heading Dr. W. S. Hedley contributes to the Lancet an interesting article on recent progress in electrotherapy, in which he combats the scepticism that prevails on the subject in certain quarters. After dealing with different methods of applying electricity as a remedial agent, the author states that the field of electro-therapeutics seems broadening when looked at from the standpoint of modern practice, and he concludes by saying that when the usual indications fail the medical man, as they often must, he should fall back upon an "enlightened empiricism," and gently feel his way. "He will 'not ask, but try.' He will not be afraid to acknowledge that after all is said there is no such thing as a large extent but rather a process of cautious experimentation."

Parliamentary News.

REMOVAL OF THE EXTRA DUTY ON SPIRITS.

In the House of Commons on Thursday, May 2, the Budget statement for the year was presented by the Chancellor of the Exchequer, Sir William Harcourt. The only alteration is the remission of the extra 6½d. duty on spirit, which has affected chemists somewhat unfairly. The duty had yielded less than half of what was anticipated during the past year.

There is no complexity in the Budget statement this year, which the Daily News briefly puts thus:

1894-5.
Revenue realised £94,684,000
Expenditure 93,916,000
Realised surplus £768,000

This surplus, of course, goes to the liquidation of debt.

1895-6.
Estimated expenditure (including two millions extra for the navy) £95,981,000
Estimated revenue without the extra 6½d. on spirits and beer 95,662,000
Deficit  £319,000
Renewal of additional 6½d. duty on beer from date of its expiration on 1st July, estimated to yield 500,000
Estimated final surplus or margin  £181,000

It is believed that a principal reason for the non-realisation of the estimated increase in the spirit duty arising out of the added impost of sixpence, to which the Chancellor of the Exchequer alluded, is that dealers have abstained as far as possible from clearing spirits out of bond in anticipation of the probable relief announced last night. It is expected that after July 1 there will be an immense clearance, by which the revenue will proportionally benefit.

THE HEMP DRUGS COMMISSION.

In the House of Commons on Friday, May 3, Mr. Cairns asked the Secretary of State for India if he was aware that the report of the Hemp Drugs Commission appointed by the Government of India in consequence of action taken in this House was, as long ago as August of last year, distributed to the Times of India, the Pioneer, and the Englishman.

Mr. Fowler said that his answer was in the negative.

LONDON UNIVERSITY.

In the House of Commons on Tuesday last, Mr. Acland informed Mr. D. Ambrose that a Bill in pursuance of the recommendations of the Royal Commission, relative to the London University, would be introduced in the House of Lords on Thursday.
Miscellaneous News.

[Readers are invited to send local information of pharmaceutical interest. When newspapers are sent the paragraphs to be noted should be plainly marked, whilst cuttings should be verified by the addition of source and date.]

ROYAL INSTITUTION.—The annual meeting of the members of the Royal Institution of Great Britain was held on May 1 at the house of the Institution in Albemarle Street, James Crichton-Browne, F.R.S., being present. The annual report of the Committee of Visitors for the year 1894, testifying to the continued prosperity and efficient management of the Institution, was read and adopted. The Real and Funded Property now amounts to above £102,000, entirely derived from the contributions and donations of the members, and of others appreciating the value of the work of the Institution. Sixty-two new members were elected in 1894, and sixty-three lectures and nineteen evening discourses were delivered in 1894. The books and pamphlets presented in 1894 amounted to about 242 volumes, making, with 576 volumes purchased by the managers, a total of 820 volumes added to the Library during the year. Thanks were voted to the President, Treasurer, and the Honorary Secretary, to the Committees of Managers and Visitors, and to the professors, for their valuable services to the Institution during the past year. The following gentlemen were unanimously elected as Officers for the ensuing year:—President: The Duke of Northumberland, F.G.; Treasurer: Sir James Crichton-Browne; Secretary: Sir Frederick Bramwell, Bart.; Managers: Sir Frederick Abel, Bart., K.C.B., Captain W. de W. Abney, C.B., the Right Hon. Lord Amherst, Mr. William Anderson, Sir Benjamin Baker, K.C.M.G., Messrs. John Birkett, William Crookes, Edward Franklin, Charles Hawkinsley, John Hopkinson, Alfred Bray Keane, George Matthey, the Right Hon. the Marquis of Salisbury, K.G., Messrs. Joseph William Swan, Basil Wood Smith; Visitors: Messrs. John Wolse Barry, C.B., Charles Edward Beevor, M.D., Arthur Carpsael, Carl Haag, Victor Horsley, Hugh Leonard, Sir Joseph Lister, Bart., M.D., Messrs. Laohlan Mackintosh Rate, Alfred Gordon Salamon, Felix Semon, M.D., Henry Virtue Tebb, Silvanus P. Thompson, John Westlake, Q.C., His Honour Judge Frederick Meadows White, Q.C., and Sir William H. White, K.C.B.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on the 6th inst., Sir James Crichton-Browne presiding. The following were elected members:—Mr. Henry Irving, Mr. Henry Perigal, Mrs. Slingsby Tanner, Mr. J. H. Fry, Mr. Thomas Muir, Mr. Harold Smith, and Mr. W. S. Smith. The special thanks of the members were returned to Mr. George Matthey for his donation of £50 to the fund for the promotion of experimental research at low temperatures.

CARBOLIC SMOKE BALLS AND MEDICINE STAMPS.—The Patent Medicines Journal remarks that the Carbolic Smoke Ball Company, Limited, of Oxford Street, W., seems to be a trifle mixed on the stamp question. The Company has been summoned for selling a box of carbolic smoke ball without a stamp. In 1890 the Inland Revenue people said that it was not necessary to stamp the article in question, but four years later they have discovered that a stamp ought to be used, and, after obtaining a sample unstamped, took out a summons, which resulted in a fine and costs on the defendant company. "Why, however, it was not deemed necessary to use stamps from 1890 to 1894, and then to suddenly come to a different conclusion, passes the wit of ordinary mortals, but of course the I.R. must maintain their character for eccentricity."

FIRE AT A BIRMINGHAM CHEMIST'S.—On Friday evening last a fire broke out in the basement of the premises over the warehouses and laboratories of Messrs. Southall Bros. and Barclay, pharmaceutical chemists, Upper Pridy, St. Peter's Square. The services of the fire brigade were requisitioned, and after twenty minutes' sharp work with the hand-pump the flames were sufficiently subdued to permit of three firemen being left in charge for the evening. Fortunately the fire was discovered before it had made much progress, or the consequences probably would have been very serious. The actual cause of the outbreak was not discovered, but the fire occurred amongst some litter and empty packing cases.

THREE TOWNS CHEMISTS' ASSOCIATION.—The junior section of the Plymouth, Stonehouse, and Devonport Chemists' Association held their monthly meeting on Thursday, May 2, at the Foresters' Hall, Octagon, Plymouth. Amongst those present were Messrs. E. T. Cocks (in the chair), T. Darke, W. Fairweather, R. H. Buckner, A. Musgrave, W. A. P. Turney, and H. Westcott (hon. secretary). On the motion of Mr. Fairweather, seconded by Mr. Westcott, it was resolved to appoint a chairman at each meeting, in lieu of electing one permanently. After the general business had been gone through, Mr. John D. Turney delivered the second of the most interesting and instructive lectures on materia medica. At the close of the meeting a hearty vote of thanks was accorded Mr. Turney, also to the chairman for presiding.

THE BAYLESE DRUG "COMPANY."—On Thursday, May 2, at the Castle of Exeter, before the Registrar (Mr. R. R. M. Daw), the examination in bankruptcy took place of William Dale Baylese, of 50, Union Street, Torquay, chemist and druggist, trading under the style, firm, or company of the "Bayles Drug Company, Limited." This is the case (mentioned in last week's Journal, p. 987) in which a question is raised as to whether certain proceeds of a sale belonged to the Bayles Drug Company, which, it is alleged, was a bogus affair, or to the debtor, Baylese, personally, and an action is pending as to an execution levied by the Sheriff against the Company. Mr. J. I. Carter, Torquay, represented the petitioning creditors; and Mr. Clode, Torquay, the debtor. Examined by the Official Receiver (Mr. T. Andrew), debtor stated that the gross liabilities amounted to £985, and the deficiency to £729. He started business at Torquay in December, 1893. Prior to that he was conducting, at Stoke-on-Trent, the business of a drug merchant, which he sold to his brother for £800, who paid him £500 and gave three bills for £100 each. He received no money from his brother until he started business at Torquay. He paid Mr. Naish £320 for the business at Torquay, the latter not being satisfied with the valuation of £309. The whole of the money he received from his brother he put into the business after paying Mr. Naish. His takings, per cash-book, for the period from December, 1893, to June, 1894, were £533. There had been no recent entries in the cash-books, and the leaves had been discarded owing to a misunderstanding at the outset as to the method of keeping the accounts. Two of the bills given by his brother had been met, and the money put into the business
OPENING OF THE SCHORLEMMER LABORATORY.—On May 3, at the Owens College, Manchester, Dr. Ludwig Mond formally opened the Schorlemmer Laboratory, which, the Manchester Guardian remarks, is the result of the general feeling that the memorial of the late Professor Schorlemmer would be the erection of a laboratory for organic chemistry, to be called after his name. A subscription list was accordingly opened, and the appeal, which was generously headed by Dr. Mond, was so well responded to, both in this country and in Germany, that in a short time a sum of £2500 was subscribed. In view of the steady increase in the number of students, the Council had meanwhile become convinced of the necessity of extending the chemical department. They accordingly accepted the fund raised under the Schorlemmer Memorial Fund Committee, and instructed Mr. Alfred Waterhouse to prepare plans for a Schorlemmer Organic Laboratory, and for a new laboratory for elementary students, on a plot of land adjoining the present laboratories acquired by the College for the purpose of their extension. The Schorlemmer Laboratory is at the end of the main corridor in the old chemical building, measures 60ft. by 30 ft., and has an arched roof 30 ft. high. It is designed to accommodate a professor, two demonstrators, and thirty-six students, and is fitted in the most complete manner, with every requisite for the important work to be carried on within it, some particulars being arranged after the plan of the Munich laboratories. The lower laboratory is designed for forty-five students. The fittings are similar to those in the old laboratories designed by Sir Henry Roscoe. The reagent-room, 20 ft. by 20 ft., communicates by a flight of steps with Burlington Street. The total cost of the new building is £4800.

Sir H. E. Roscoe, M.P., gave a brief sketch of Schorlemmer's life, and described how he came to him as assistant, and remained his faithful and intimate friend for thirty-four years. When Dittmar received the chair, he was placed in the position of sole assistant and demonstrator to a somewhat increased number of students. In that new position his powers as a laboratory teacher soon made them-selves manifest, and much of the subsequent success of their laboratory was due to his tact and knowledge, and to the genuine enthusiasm which he displayed in imparting that knowledge to others. He (Sir H. Roscoe) remembered as though it were only yesterday the first beginning of the original work which had made his name eminent amongst the chemists of the time, and, as he mentioned, who was then occupied with the manufacture of benzine by the distillation of cannel coal—for the supply from the gasworks was then not equal to the demand—sent him (Sir H. Roscoe) some of the light oils which he obtained in his process. They were of no commercial value, but of the greatest scientific value. He submitted these oils to Schorlemmer, knowing their investigation was a hard nut to crack, but knowing also that Schorlemmer was the man to crack it. The examination of these oils was the beginning of Schorlemmer's scientific fortunes. Schorlemmer's scientific work was written in every manual of organic chemistry throughout the world, and had been described fully in his own 'History of the Rise and Development of Organic Chemistry,' recently edited by his pupil, Professor Smithells, whilst his investigations on the constitution of the hydrocarbons marked an era in modern organic chemistry. That his work in this branch of knowledge was of great value, it, like much other work of a similar character, enabled other men to build up an industrial structure the value of which was measured by millions of pounds sterling, and gave now employment to thousands of men. For it was not too much to say that without Schorlemmer's discoveries the knowledge of the constitution of the carbon compounds which we now possess, as typified by Kekulé's theory, could not have arrived at. Schorlemmer's power of work was simply prodigious, and his knowledge of chemical literature deep as well as broad. He was an author and made use of their admirable medical library. He, of course, lived and died a poor man, though had he chosen he might have amassed a large fortune. His distinction was, however, none the less on that account, but, as some would think, all the more.

Dr. Ludwig Mond said the opening of the first laboratory solely devoted to the study of organic chemistry in the Manchester University was certainly to be welcomed. That university could boast of a professor of that subject, marked a distinct step forward in the development of science in this country. In dedicating that laboratory to the memory of Schorlemmer, to whom science and that University owed so much, they must all regret that he was not with them on this occasion to receive a special laboratory at his disposal. Nevertheless, the spirit which he infused into his work, his pupils, and his books would be the most valuable endowment which the new building inherited, and would manifest itself in the work of all those who had the good fortune to work there, if they approached their tasks with the same single-mindedness and love of truth that marked the late Professor Schorlemmer. His work had been singularly fruitful in clearing up and putting on a sound basis the modern theory of organic chemistry called by him so appropriately "the chemistry of the carbon compounds." For it was Schorlemmer who provided the fundamental proof of the equal value of the four valencies of carbon, the very corner-stone of the great edifice by which we had obtained an insight into the simple laws upon which the immense variety of organic compounds was built up. And the value of the work not only extended to the constitution of the molecule, for in many cases they succeeded in penetrating into the constitution of the more complex compounds or other elements, the more they were forced to apply the same laws which
they owed to the study of organic chemistry, to explain their constitution.

The liquefaction of gases.—Professor Dewar continued his historical retrospect of the subject of liquefying the so-called "permanent" gases at the Royal Institution last week, and from a scientific point of view, remarks the Daily Chronicle, the discourse was highly interesting, and many of the illuminative experiments were of great importance. The lecturer pointed out the work done by Faraday in the way of liquefying gases by means of the cooling properties of solid carbonic acid, further heightened by the process of boiling off the carbonic snow in a vacuum, thereby considerably lowering its boiling point. By this means the very low temperature of 110° below zero (Centigrade) was reached, and with adequate pressure nearly all the compound gases gave up the contest at this point and passed into the liquid state. But still oxygen, nitrogen, marsh gas, and hydrogen resisted. In 1845 Faraday thought to make a further step forward by using liquid nitrous oxide (N₂O) as a cooling agent, but to no avail. However, they got down to 120° below zero. Then followed elaborate experiments by the celebrated Regnault to determine the exact relationship of what are known as the "three constants"—namely, pressure, temperature, and volume.

Professor Dewar addressed the Institute a series of still more important experiments, which remodeled the results of Regnault, and later on Van der Vals, Thompson, and Armitage conducted researches which may be said to have fairly settled the modern theory of gaseous volume, temperature, and pressure. In the meantime two ingenious commercial men of chemical leanings, one M. Pictet, of Geneva, and the other M. Callietet, of Paris, applied the new theories on a large scale to the liquefaction of oxygen gas. They were working both unknown to the other. Callietet used two currents of liquid carbonic acid and liquid sulphuric acid, continuously circulating under exhaustion, and applied the intense cold produced to oxygen under a pressure of 300 atmospheres—a daring sort of proceeding—with the result that he obtained large quantities of liquid oxygen spray. He was the first who ever produced liquid oxygen, and both he and Pictet knew that a compound containing "permanent gases" could be liquefied under pressure if a sufficiently low temperature was only applied. Pictet opened very important ground in turning his attention to the hydrocarbon gas, ethylene, as a means of producing cold. It can be liquefied, and sold at 100 degrees below zero. When evaporated in a vacuum, very low temperatures can be obtained.

Professor Dewar showed how liquid ethylene freezes water when poured on the surface, and made several other experiments to illustrate its highly volatile nature. In his final lecture the Professor intends to show how ethylene was ultimately used to solve the problem of liquefying the atmosphere. He remarked, however, in concluding his lecture that a heated controversy had arisen out of the application of ethylene for this purpose. Pictet started by using as Faraday did solid carbonic acid—at the ordinary atmospheric boiling-point—but before he had gone far two other experimenters got ahead of him by using it at a vacuum boiling-point. They naturally succeeded in getting to the desired goal, but it was said that if they had not rushed in and anticipated the way, it was anticipated, Pictet would in due time have arrived at the same point, and that therefore the originality of that discovery was his right.

EDINBURGH PHARMACY ATHLETIC CLUB.—The annual general meeting of the Club was held in the Pharmaceutical Society's Hall, 38, York Place, Edinburgh, on Wednesday, May 1, at 9.15 p.m., Mr. W. D. Jamieson, President, in the chair.

The minutes of last meeting were read and approved.

The President said he had to congratulate the Club on having reached the end of another year in their history. They were now in a very flourishing condition, both in regard to membership and funds. The Club, he thought, had done a great deal for its members by encouraging a taste for athletics among those connected with the profession.

The Secretary then read the annual report, showing a total membership of 88. The most successful section during the year had been the golfing section, conducted by Mr. Welsh.

The Treasurer then read the financial statement, showing a balance of £2 2s. 9d. The income at the annual sports amounted to £58 10s. 11d., and they had expended, on prizes and rental, £45 10s. 3d.

The report and statement were unanimously adopted.

On the motion of Mr. Gibb, seconded by Mr. Birnie, it was agreed to reduce the annual subscription to 3s. 6d. for members, and 2s. for apprentice members.

It was resolved to add the following new rule:—

"Members of this Club entering under the name of the Edinburgh Pharmacy Athletic Club, and establishing Scottish records in open flat-race competitions, or gaining a Scottish flat-race championship, shall be awarded a gold medal."

The arrangements as to apprentice races at the proposed annual sports on May 23 were remitted to the Committee to decide, and the football regulations were adhered to.

The following office bearers were then elected for the ensuing year:—Honorary President, Mr. D. MacLaren; President, Mr. John Brown; Vice President, Mr. W. B. Cowie; Secretary, Mr. J. P. Gibb; Assistant-Secretary, Mr. G. F. Anderson; Treasurer, Mr. A. S. Birnie; and as members of Committee, Mr. Jameson, Kininmonth, Leitch, McBain, Paterson, Somerville, and Sutherland.

On the motion of Mr. Mathewson a hearty vote of thanks was awarded to Mr. Gibb and other office bearers, and a similar vote was cordially awarded to the retiring President, Mr. Jameson, on the motion of Mr. Birnie.

The meeting then closed.

Notes in Brief.

Emulsions are frequently made in America by plunging into the mixture of ingredients a vaginal syringe, and working it vigorously until the emulsion is perfected.

Liquid glue of great adhesiveness, that dries quickly and keeps well, can be made, according to the Pharmaceutische Centralblatte, by dissolving glue or gelatin in aqueous chloral hydrate solution.

Argon is readily shown to be present in the atmosphere, and isolated, according to M. Guntz (Comp. rend.), on absorbing the nitrogen by means of lithium heated to a temperature below a dull red heat.

Cholesterol of the skin are separated by Liebreich into those with a high melting point, resembling wax and containing acidic acid, and those with a low melting point.
Poisoning Cases and Inquests.

Sulphurous Acid.—Ellen Wilkes, the daughter of a tradesman living at Stonebridge Park, Willesden, died on Thursday, April 30, from the effects of drinking sulphurous acid. Verdict: "Accidental death."

Carbolic Acid.—Thomas Bailey, aged 65, died on Thursday, April 25, at Oldfield Farm, Dunham Massey, from the effects of carbolic acid, self-administered. Verdict: "Suicide whilst of unsound mind."

Carbolic Acid.—At the inquest held at the Rolle House, Endon, on Monday, April 30, on the body of Frank Michael Sanders, aged 31 (see ante, p. 988), a verdict of "Suicide whilst temporarily insane" was returned.

Prussic Acid.—Henry William Hall, aged 31, died on Monday, April 29, at 89, Holland Road, Britonry, from the effects of prussic acid, self-administered. Verdict: "Suicide whilst of unsound mind."

Prussic Acid.—James Dixon, described as a chemist, but not registered as a chemist and druggist, died on Friday, May 3, at Manby Street, Stratford, from the effects of prussic acid, self-administered. Verdict: "Suicide whilst insane."

Potassium Cyanide.—Evelyn Ward, aged 32, died on Sunday, May 5, at 37, St. Paul's Street, Huddersfield, from the effects of morphia, taken to induce sleep. Verdict: "Death from poisoning by phospine."

Bat Poison.—James Hale, aged 25, died on Tuesday, April 30, while on the way to the Golf Hospital, Dudley, from the effects of a rat poison, self-administered.

Potassium Cyanide.—At an inquest held on May 6, at Margate, on the body of Edward George Knott, who was found dead in his bed with an empty 1 oz. prussic acid bottle beside him; but no evidence was produced to prove who supplied it. The label was found on the floor of a bar in the locality almost obliterated; the pieces were carefully placed on paper, when the following letters appeared, A. C. D. R. Y. P. Verdict: "Deceased died from prussic acid, self-administered whilst temporarily insane."

Trade Marks Applied For.

[From the Trade Marks Journal.]
No. 185,998.—AN OINTMENT FOR HUMAN USE.—London, W. March 4, 1895. Device—An animal on a bough. No. 185,440.—A MEDICINAL POWDER enclosed in cachets of wafer paper, for the cure of headaches, neuralgia, and rheumatism; also a linament for the cure of neuralgia and rheumatism.—David Donaldson Buchanan, 8, Garslyne Street, Frockhock, Forfarshire. February 8, 1895. For cachet, words: "Evenia" and cachet, words: "Evenia," and liniment for neuralgia and rheumatism. The essential particular of each is the word "Evenia."

No. 188,382.—PERFUMERY (including toilet articles and preparations for the teeth and hair).—Blondon et Cie, Pont de l'Arche, London, W. 1896. Device—A cupid in chariot drawn by a butterfly.

No. 188,464.—CHEMICAL SUBSTANCES prepared for use in medicine and pharmacy.—Henry Daubeney Brandreth, 22, Hamilton Square, Birkenhead. March 20, 1895. Word, "Exarno."
done much to make that history, and in the records of the Board he has written it. He was the constant adviser, officially and voluntarily, of medical officers of health throughout the country, and was the last President of their association. Sir George was a past President of the American Institute of Physicians, Fellow of the Royal Society, a Fellow of the Royal College of Physicians, and Censor to that college from 1891 to 1894. For many years he was a member of the Council of University College. In that capacity, and in that of a member of the Senate of London University, he was instrumental in affording facilities for the education of women.

On May 6 Karl Vogt died at Geneva. (Aged 78.) The celebrated German biologist, according to the Times, was born at Geissen, and first came into prominence as the active collaborator of Agassiz and Deper. He was joint author of the famous work on fresh-water fishes. After a residence of two years in Paris and a visit to Italy, he returned to Germany to occupy a chair at the University of his native town, but his profeesional career was cut short by the revolution of 1848. He threw himself with ardour into the ranks of the Communists, and was, for a time, a member of the German National Assembly, where he distinguished himself as a brilliant orator and an untiring advocate of democratic progress. He followed the Parliament on its transfer to Stuttgart, and was one of the last supporters of Nationality. His services to the cause which he had espoused, however, cost him his Professorial Chair, and obliged him to leave Germany. He then retired to Berne, and afterwards to Nice, where he resumed his biological researches. In the following year he was appointed professor at Geneva, and from that time identified himself with the future life of the country of his adoption, becoming a member of both the Federal and National Councils. Of his voluminous works, perhaps the most celebrated was his book entitled 'Science and Superstition,' which was a fierce polemic against the intervention of religion in science, and at once made its author one of the leaders of scientific materialism in Germany. Another book which created considerable stir was Vogt's 'Investigations into Animal Communities,' which consisted of a scathing criticism of the vices and weaknesses of human societies.

ARNOLD.—On May 16, Alfred Arnold, chemist and druggist, of Pentyla Aberavon, Port Talbot (late of Carn-Avon, Glamorganshire, previously of Kingsland, London, N.E.), in his eightieth year. Registered as having been in business prior to August, 1868.

Patent Office Business.

APPLIcATIONS FOR PATENTS.
[From the Illustrated Official Journal (Patents).]
No. 7944.—Improvements in or relating to bottle-washing machinery. April 22, 1895.
No. 7963.—Improvements in bottle-filling machines for filling bottle containers with carbonated liquors, filled from fermenters or otherwise, and for closing bottles by new stoppers or corks worked by hand or power. April 22, 1895.
No. 7970.—A label clip. April 22, 1895.
No. 7988.—An improved product for use in the preparation of articles of food. April 22, 1895.
No. 8004.—Improvements in self-sealing bottles. April 23, 1895.
No. 8038.—Apparatus for racking liquids. April 23, 1895.
No. 8064.—Improvements in or substitutes for children's teething pads or soothers. April 23, 1895.

PATENTS PUBLISHED APRIL 27.
Nickel and Cobalt (Manhes, P.).—The invention is comprised under two patents numbered 6914 and 6894 of 1894, and refers to the preparation of commercially pure nickel and cobalt from the ores. According to the first patent, the sulphide of nickel or cobalt obtained as a matte in the ordinary smelting operations, is broken and mixed with a mixture of the oxide and chloride of calcium, barium, magnesium, potassium or sodium, or of one and the chloride of another of those metals. The invention prefers to use "a mixture of lime and chloride of calcium, or, better still, chloride of lime." On heating the mixture in a furnace, the matte loses its sulphur, part of which escapes as sulphur dioxide, while part remains in the form of sulphide. Patent No. 6914 provides for the elimination of iron. The ore is melted in an ordinary furnace, from which it runs into a converter furnace, where it is mixed with borax (natural calcium borate). It is then treated with an air blast, which drives off much of the sulphur and oxidises the iron so that it combines with the borax and passes into the slag. Finally, the slag is run off and the residual material is cast. Patent No. 6914, to remove the remainder of the sulphur. The boraxic ore may be replaced by the borax or other suitable salt of sodium, potassium or aluminium.
Labelling poison bottles, etc. (Maud, W. B.).—A suitably shaped metal label is provided by the invention, so as to indicate the contents, and somewhat larger than the bottle, is secured thereto so that no one can open the bottle without being warned of the contents by touching the disc. No. 9073 of 1894.
Turpentine and Potassium (Vautin, C. T. J.).—The chloride or other salt of sodium or potassium is fixed in a crucible or other vessel upon a surface of molten lead or tin, which forms the cathode of an electric circuit. The anode may be of carbon. The potassium or sodium alloy with the tin or lead, as fast as it is formed, the resultant alloy is transferred through a pipe in the bottom of the vessel into a retort in which it is distilled, preferably by the heat from carbon rods heated by electricity. The potassium or sodium condenses in the retort, and the lead or tin is used again. No. 10,197 of 1894.
Sulphur candles or incensators (Kingsett, O. T.). A stick of sulphur is wrapped in a casing of tin or other metal foil whose upper end is bent over to secure a piece of fabric soaked in sulphur, and serving as a lighter for starting combustion. The foil may be perforated or "serrated." The "candle" may be nearly submerged in water which evaporates as combustion proceeds, but does not danger fire. No. 10,445 of 1894.
Deodorising petroleum, etc. (Tempère, A. J.). Petroleum or other hydrocarbon is mixed with amyl-alcohol in the proportion of about 10 grammes per litre of oil. The odour of the amyl-alcohol overcomes that of the petroleum, but is said not to interfere with its use. No. 10,772 of 1894.
Inhaler (Quaglio, J.).—The invention comprises a cup-shaped mask having an absorbent interior surface and connected through a tap with an receptacle containing the chloroform, eau de Cologne, etc., to be inhaled. On opening the tap and squeezing a collapsible rubber ball, the liquid is driven into the mask and, having saturated the absorbent surface, the excess is allowed to return by permitting the ball to re-expand. The collapsible ball may itself constitute the reservoir. No. 10,950 of 1894.
Massage, etc. (Lake, H. H., communicated from Schaefer, E.).—For the purpose of massage or for rubbing-in ointments, etc., the inventor employs a metal or other ball rolling freely in every direction in a casing which serves as a handle and extends far enough over the ball to prevent it from falling out. The ball is removable, and means for supplying an electric current to it are fitted to the casing. No. 11,000 of 1894.
Filter (Chamberland, C. E.).—Refers to patent No. 5589 of 1894, and consists in filtering and sterilising water by passing through a porous paper or metal filter. The filtration is now effected by passing the liquid successively through two or more such filtering media, the area of the first and following surfaces being so adjusted that the practical constant outflow shall be obtained. Each section of the filter may be a single tube or a series of them. No. 11,090 of 1894.
NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally.]

**CALCICUM GLYCEROPHOSPHATE PREPARATIONS.**

[851.] Professor Gay, of Montpellier, prepares an aerated solution of calcium glycerophosphate, as follows (' Bull. de Pharm., Med.'):—Calcium glycerophosphate, 10 to 30 Gm., and citric acid, 5 to 7 Gm., are dissolved in sufficient distilled water to make 1 litre. Sodium bicarbonate, 4 Gm., is then introduced into the bottle, which is immediately closed. He also prepares a syrup by dissolving calcium glycerophosphate, 10 Gm., and citric acid, 1 Gm., in distilled water, 340 Gm., and then dissolves in the solution without heat sugar, 610 Gm. Simple or aromatic syrup is then added to make up to 1 kilo.

**CREOSOTE PILLS.**

[852.] On the grounds that albumin chemically fixes creosote, Schreiber has devised the following method for preparing pills of that substance, which, he claims, are accurate in dosage, and which keep well. Creosote, 6 grammes; dried egg albumin, 3 grammes; distilled water, 10 drops. Mix and add powdered licorice root and extract of licorice sufficient to mass. Divide into sixty pills. These pills are inapplicable in water, but are dissolved in the process of digestion.

**COPPER HEMOL.**

[853.] This compound of copper and hemoglobin, which is represented by the formidable formula—

\[
\text{Cu}_{2} \text{O}_{4} \text{Fe}_{2} \text{O}_{4} \text{S}_{4} \text{O}_{4}\cdot \text{H}_{2} \text{O}
\]

has been introduced by Merck. It is proposed that it should be administered as a powder thus:—Copper hemol, 0-1 gramme; chocolate powder, 0.5 gramme. One powder to be taken three times daily. In cases of debilitated digestion the powders should be taken with the meals. The dose should not exceed 0.5 grammes ('Apoth., Zeit., April 17, 1895').

**MASS FOR MEDICATED BOUGIES.**

[854.] Cacao butter, 4 parts; powdered gum acacia, 2 parts. Mix intimately and, with constant kneading, mix in glycerin, 1 part, and water, 2 parts. If required, the quantity of cacao butter may be slightly increased ('Prickler; Rev. Thérapeut.', Feb., 1895).

**TRAUMATISM.**

[855.] Traumaticin is a saturated solution of gutta-percha in chloroform; it is most advantageously prepared as follows:—The heaviest, coloured gutta-percha procurable is cut into small pieces and macerated with 12 or 15 times its weight of pure chloroform for twenty-four hours, with frequent agitation. The mixture is then transferred to a retort, and about one-third of the chloroform distilled off over a water bath. The traumaticin that is obtained is a thick homogeneous liquid, to which the requisite medicament may be added. For ichthyol traumaticin 3 parts of ichthyol are added to every 10 parts—similar proportions are used for salol, lysterol, and phenol. Corrosive sublimate is added in the proportion of 1 part of sublimate for 100 parts of simple traumaticin. If the simple traumaticin should be coloured, and a colourless medica-ment is to be added, it may be decolourised by means of animal charcoal. It is best applied with a brush of hog’s bristles, and forms a thin impermeable, pliable pellicle when the chloroform dries off. It gives rise to no discomfort, except a sensation of burning when first applied, due to the chloroform. Traumaticin of ichthyol is of special service in the case of erysipelas. ('Bull. Gen. de Thérap., Feb., 1895').

**NOTICES, LETTERS, AND ANSWERS TO CORRESPONDENTS.**

**COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD BE REACH THE OFFICE, 17, BLOOMSBURY SQUARE, LONDON, W.C., ADDRESSED "EDITOR," NOT LATER THAN THE FIRST POST OF WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING. TELEGRAPH ADDRESS:—"PHARMACEUTICAL JOURNAL, LONDON."**

See notes, letters and answers to correspondents.

**NAMES AND FORMULAE must be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.**

*" Queries will be replied to as early as possible after receipt, answers of sufficient general interest being given under the heading NOTES AND QUERIES."

**LETTER.**

**MAJOR EXAMINATION.—Mr. S. C. Frederick Mische of The Pharmacy, St. Austell, writes as follows:—"W: you allow me, through your Journal, to thank the gentlemen who have sent me their names and addresses to be added to the memorial to be placed before the Phamaceutical Council. I would suggest that the example of some be followed, who have not only sent their own names but canvassed others (in one instance twenty names), for if we so, we should soon have an imposing and influential list. The list will be open until the end of May."**

**ANSWERS.**

**J. W. BROWNE.**—Your letter has been sent to 5 Serle Street, where it should have been directed. **W. A. MANNING.**—Letter with enclosure received. **E. F. HARRISON.**—Received with thanks. Very satisfactory. **J. J. BROWN.**—See footnote on page 953. **C. S. THOMPSON.**—Please send on the illustrations as early as convenient. **STUDENT.**—No such compound has yet been obtained.

**COMMUNICATIONS, LETTERS, Etc., have been received from Messrs. Bayley, Bradley, Brathwaite, Brown, Cripps, Fitzgerald, Grove, Harrison, Harvey, Henry, Hewitt, Hill, Holloway, Howe, Kirkby, Macartney, Ma-shall, Michell, Millard, Moffatt, Phillips, Reynolds, Shapley, Talis, Thompson, Woolridge.**

**PUBLICATIONS RECEIVED.**

[Publishers are requested to state the price of books sent for review.]

**OFFICIAL GUIDE TO THE MUSEUMS OF ECONOMIC BOTANY AT THE ROYAL GARDENS, KEW. NO. 2—Monocotyledons and Cryptogams. Pp. 100. 4d. to the director.**

**ORGANIC CHEMISTRY, THEORETICAL AND PRACTICAL.**

RICHARD OWEN.

"THE GREATEST ANATOMIST OF HIS AGE."

So strong has become the scientific spirit, so strong the classificatory instinct, that unconsciously we take it for granted that some label denoting a characteristic must be placed over the niche in which will be deposited the deeds of the nineteenth century. It has been suggested that it will be known as the age of railways, or the age of electricity, or the age of steam, or the age of some mental or political attitude of the people, as the critical age or the democratic age. But it is vain to attempt an estimate of the value either of the literature, thought, or deeds of the age. They are so near as not to permit even an approximately true perspective being obtained of them. Of this, however, we may be sure that this century has witnessed the acquisition of such a store of scientific facts as no previous age has ever known—facts which are gradually forming a broad foundation for an adequate scientific philosophy. What was done for chemistry in the latter half of the eighteenth century by Scheele, Priestley, Cavendish, and Lavoisier, in the accumulation of the records of precise observations, has been done for comparative anatomy by numerous workers in this century, and the foremost amongst these was Richard Owen, whose biography has recently been published by Mr. Murray.

The story of Owen's cheerful life is told chiefly through the medium of his letters and of extracts from his wife's diary. The air of thankful satisfaction which pervades his correspondence, and is reflected by Mrs. Owen's daily records of their outings and comings, exerts a benign influence in these days of cold pessimism.

Richard Owen was born on July 20, 1804, at Lancaster, in a house which is still standing in Blackburn Street. At the age of six years he was sent to the old Lancaster Grammar School, where he was a contemporary with Whewell, a carpenter's son, who became the famous Master of Trinity. In 1820 he was apprenticed to a Lancaster surgeon and apothecary. His master dying in 1822, he was transferred to Mr. Seed, and in 1823 he had to find a third master, in consequence of Mr. Seed accepting a post in the Royal Navy. It was during his apprenticeship that the two episodes transpired of which in later years he gave an account in 'Hood's Magazine.' Although these the pretty familiar, the story of the n-gro's head is sufficiently unique to tempt quotation here. To use Professor Owen's own words: "My worthy preceptor was called out one evening to the case of a sailor who was brought home in an apoplectic fit after receiving a heavy fall in a drunken fray at a public house. The doctor found it a hopeless case, and the man passed from his stupor into death. After his death his widow and daughter retired to one of the little houses which face the steepest part of the hill leading to the castle gates. One evening they were talking about the slave trade, in which occupation it appeared the unfortunate husband and father had spent a large part of his active life. The two women had finished their meal and were sitting before the fire, by the light of which they were holding their conversation. The mother was feebly attempting to make a case in defence of the traffic, when on a sudden the attention of both was roused by a sound of footsteps rapidly approaching the door, which was immediately burst open by a heavy blow. A piercing shriek came from the mother, who rushed into the adjoining bedroom; the daughter started and turned towards the cause of the noise and her mother's fright, and saw what she afterwards described as the phantom of a negro slave lying on the floor, which turned its ghastly head and glared for a moment upon her with white protruding eyeballs. A figure in black entered as she fled screaming after her mother. When the two terrified women ventured at length to glance into the room from which they had been scared, all was quiet; the red glow from the fire showed everything to be as they left it. What could this be except an apparition of the captain with his negro slave, and the old gentleman himself in black pursuing them?" The true cause of the apparition was rather more substantial, but scarcely less shocking. Owen had begun to make a craniological collection, and having had one day to assist at the necropsy of a negro who had died in the castle, which is also the county gaol, he was seized with the desire to add the skull of the Ethiopian to his collection. Accordingly the same evening, a frosty one in January, he re-visited the castle, and, being on good terms with the turnkey, proceeded to the room in Hadrian's tower to possess himself of the coveted specimen. He had provided himself with a strong paper bag, and into this he placed the skull, covering the whole with his cloak. As soon as he was outside he began to hasten down the hill, but his foot slipped upon the ice-covered pavement, he fell forward and the skull jerked out of the bag, rolled down the declivity, and struck the cottage door of the widow and her daughter, finding a resting-place for an instant upon the floor of the room. Owen dashed desperately after his prize, and, gathering it into his cloak, ran off and never stopped until he reached the surgery.

Owen matriculated at Edinburgh in 1824, and in the following year came to London and became prosector to Dr. Abernethy, who in 1826 started him upon his distinguished and honourable career by procuring him the appointment of assistant to the Conservator (Mr. Clift) of the Museum of the Royal College of Surgeons. The appointment was made with a view to Owen undertaking the arrangement of the collections formed by John Hunter, which had recently been placed in the care of the college. In subsequent years Owen and Mr. Clift's daughter were married. The union must have been an almost ideal one. Throughout these volumes respectful love and care for his wife are exhibited in all Owen's letters and actions. And on her part a loving devotion to, and veneration for, her husband added all to her own fame.

From this point Owen's life was one long continuous succession of honours and pleasure. The proverbial ups-and-downs never came within his experience. He appears to have been spared all sorrows excepting those which make the fundamental bals of all the music of mortal life. But so far from spoiling his spirit, they unduly elevat-
RICHARD OWEN.

[May 16, 1856]

ing him, the honours which were literally showered upon him only seem to have increased the thankfulness of a disposition which was not envious in the least. He was justly the envy of all the men of science, and this was a consequence of his intense love for his work. It is apparent that he experienced the satisfaction born of well-earned reward, but there is no evidence that this feeling ever gave birth to arrogance; rather he was humbly grateful that his powers were competent to earn his rewards.

He writes in the year 1830:—"I made Cuvier's personal acquaintance at the Museum of the College of Surgeons, and was specially deputed to show and explain to him such specimens as he wished to examine. There were no special merit in my being thus deputed, the fact being that I was the only person available who could speak French, and who had at the same time some knowledge of the specimens. Cuvier kindly invited me to visit the Jardin des Plantes in the following year." To a man of Owen's tastes a meeting with the great anatomist must have been big with desires for ambitious work in the future. The acceptance of Cuvier's invitation in the succeeding year doubtless confirmed the desires as resolutions.

He was a friend with the Rev. Dr. Buckland seems to have begun when Owen was twenty-eight years of age, by his sending Dr. Buckland one of the proofs of his work on the Pearly Nautilus, together with a letter in which he says:—"Since the decease of the lamented Cuvier, there is no one whose opinion on this work I look for with more anxiety than your own." The friendship between these two leaders of scientific thought and research became very close and cordial. The year 1834 witnessed Owen's appointment to the professoriate of comparative anatomy at St. Bartholomew's, and his election as a Fellow of the Royal Society. In 1836 he was appointed Hunterian Professor at the Royal College of Surgeons. This latter appointment was a source of peculiar gratification to him, and the twenty-four annual lectures which he delivered from this chair were the result of his best thought and work. Up to 1837 Owen had to some extent cultivated a medical practice, but experiencing a pressure of scientific work, he decided to relinquish it altogether and devote himself entirely to research. He was an indefatigable dissector and his opportunities were many. The animals which died at the Zoological Gardens were at his disposal, and so rapidly had his fame as an anatomist spread that specimens were forwarded to him from every quarter of the globe. Everything that was new to him was subjected to his keen knife and keener observation. A note in Mrs. Owen's diary is as follows:—"The defunct rhinoceros (late of Wombwell's menagerie) arrived while R. was out. I told the men to take it right to the end of the long passage where it now lies. As yet, we feel indifferent, but when the pie is opened—". Six days later she writes:—"R. still at the rhinoceros."

The story of Owen's clever deduction as to the presence of the remains of a large terrestrial bird as large as an ostrich in New Zealand, is given in full by his biographer. It is an excellent example of the application of his powers of observation as well as of his method of ratiocination. From a fragment of bone only six inches in length he reconstructed the skeleton of the Dinornis which was afterwards to be found. No wonder the Committee of the Zoological Society refused to endorse this bold conclusion, and only with hesitation consented to publish his paper in the "Transactions," with the proviso that the responsibility of it rested exclusively with the author. The subsequent verification of his conclusions was so complete that when a perfect femur arrived, and was placed over the drawing of one made by him, when he was in possession of the small fragment only, they coincided perfectly.

The round of scientific work, followed with such zest, was, nevertheless, not allowed to become the round of life. Science never caused him to neglect for it harm so many others, into a bore. If Carlyle, whose keenness of scent for every species of cant was so pronounced, could speak of him as a man who "was neither a fool nor a humbug," there is every reason to believe that the negative praise was thoroughly deserved. Owen was a confirmed but discriminating novel-reader; a proficient chess-player, a cultured musician, being a good executant upon the 'cello, and a frequenter of the playhouse. Being thus a man of taste, and having secured an early introduction into the best society of London, he was in constant requisition at all the society functions of his day.

A considerable share of work in connection with the organisation of the Great Exhibition of 1851 fell to his lot. He was also a Juror of the Universal Exhibition of Paris in 1855. For his services in connection with this he was created a Knight of the Legion of Honour.

In 1856 Owen was appointed to the new office of Superintendent of the Natural History Department of the British Museum. This was done at the suggestion of Lord Macaulay, whose attention had been drawn to the possibility of this department being neglected unless placed under the control of a man of science. Macaulay was also actuated by a desire to make suitable provision for Owen, who, he wrote, "is an honour to our country. . . . A poet, a novelist, an historian, a painter, a sculptor, who stood in his own line as high as Owen stands among men of science could never be in want except by his own fault. But the greatest natural philosopher may starve while his countrymen are boasting of his discoveries, and while foreign academies are begging for the favour of being allowed to add his name to their lists."

Wiseiy, we think, has his biographer devoted a chapter to the account of Owen's scheme for a natural history museum which should be of adequate proportions and of suitable arrangement for such a display of the large collections of specimens which were stored away in Bloomsbury as should be at once interesting to the ordinary visitor, educational for the student, and easy of access to the scientific worker. After twenty-five years' advocacy of his scheme, and of fluctuating hopes and fears, begotten of our system of party politics, Owen was permitted to realise in large measure his desires in the form of the present Natural History Museum at South Kensington. A fitting memorial of a devoted scientist!

When the Prince and Princess of Wales visited Egypt in 1869 Owen was asked to join the party. The extracts taken from the letters he wrote upon this occasion consist largely of gossipy items of a very pleasing character. One of these tells how
M. de Lessepe endeavoured to play a trick upon him. Describing his visit to the Suez Canal, he writes: "The steamer had taken us up to sea so that we might view the piers of huge artificial blocks of stone intended to keep open the entry of the harbour. We then returned to inspect the artificial stonework. M. de Lessepe, with an innocent air, brought me a piece of stone with some shells embedded in it, and asked me what formation it belonged to. I said it was the most recent I had seen, and from the fossils evidently new to geology. On the whole, I should describe it as la formation Lessepienne, which pleased the old gentleman amazingly."

With the year 1888 Owen ended his official connection with the Natural History Museum, and retired to his home—Sheen Lodge, with its beautiful garden, to spend his declining years in peaceful enjoyment of such simple pleasures as are compatible with the burden of fourscore years. It was meet that nine quiet years should round off to completeness the otherwise arduous life of this truly great scientist.

Some notion of the magnitude of his labours may be gathered from the forty-nine pages chronicling the six hundred and thirty-eight articles contributed by him to general and scientific literature. Four pages are occupied with a list of the various distinctions conferred upon him.

Professor Huxley has contributed a lengthy chapter on "Owen's Position in the History of Anatomical Science," from which it appears that it is upon Owen's discoveries in anatomy and palaeontology rather than upon his philosophical speculations that his reputation will find its foundation. "His claims to high place among those who have made great and permanently valuable contributions to knowledge remain unassailable."

PHARMACOPEIA NORVEGICA.

(Concluded from page 1000.)

Lanolin melts when heated on a water bath and separates into two layers (water and wool-fat); heated till the weight is constant should not lose more than 30 per cent. If 10 grammes of lanolin are melted over a water bath with 50 grammes of water, the aqueous layer filtered and evaporated to dryness, should leave no residue.

Linctus Boracini.—Borax, 1; glycerin, 9.

Liq. Antispastici.—Liquor ammonii suci nici pyrocolis, 1; spiritus ethereus, 1.

Liq. Kalii Abscisici.—Arsenious acid, 1; carbonate of potassium, 1; water, 5; warm till dissolved, add tincture of gentian, 5; and water to 100.

Liq. Ophthalmicum (eye water).—Sulphate of zinc, 2; rose water, 1000; opium wine (containing saffron), 10.

Liq. Pectoralis (chest drops).—Extract of liquorice, 1; fennel water, 3; anisated ammonium, 1.

Mistixura Acida.—Dilute sulphuric acid (10 per cent. SO₃), 1; water, 40; raspberry syrup, 9.

Mistixura Acid. Hydrochlorici.—Dilute hydrochloric acid (10 per cent. HCl), 1; water, 40; raspberry syrup, 9.

Mistixura Alba (chalk mixture).—Precipitated carbonate of calcium, 3; powdered gum, 3; water, 88; white syrup, 3; spirituous cinnamon water, 3.

Mistixura Aperiens (aperient mixture).—Tartrate of potassium, 3; water, 7; rhubarb drops (inf. rhel. alk.) 10.

Olius Hyoscyami is prepared by using ammonia (Dietrich's method); henbane, 50 parts, are warmed with spirit 100, and ammonia 1 for twelve hours; 250 of olive oil are then added, and the whole heated on the water bath until the spirit is dissipated; press out the oil and filter.

All other "olea infusa" are prepared in the same way, but ammonia is used only for those that contain alkaloid.

Pilulæ Colocynthidis Compositæ.—Powdered colocynth, 6; aloes, 12; scammony resin, 12; oil of cloves, 2; tallow, 9; glycerin, 9; make into pills weighing 0-1 grammes each.

Pilulæ Blaadi.—Powdered crystallised sulphate of iron, 15; powdered carbonate of potassium, 15; powdered liquorice root, and glyciner q.s., are made into 100 pills (Pilulæ Blaadii majorres), or 160 pills (Pilulæ Blaadii minorres).

Pilulæ Ferri Compositæ.—Powdered crystallised sulphate of iron, 1; powdered carbonate of potassium, 1; powdered myrrh, 2; make into pills weighing 0-2 grammes each.

Pilulæ Ferri Iodati (Blancard).—Powdered iron, 2; water, 4; iodine, 4; powdered sugar, 4; rub in a mortar till the iodine is dissolved, and add powdered althes, 2; powdered liquorice root q.s., to form 100 pills (each containing 0-05 grammes ferrous iodide).

Pilulæ Tonicæ Nervi.—Powdered crystallised sulphate of iron, 5; powdered assafetida, 5; extract of gentian, 5; to form 100 pills.

Pulpis Ipecacuanhae Opiatus (pulpis cephaëidis opia; pulvis thebacinus).—Ipecacuanha, 1; opium, 1; sulphate of potassium, 8.

Pulpis Refrigrans (cooking powder).—Lemon oleo-saccharate, 12; powdered nitre, 12; powdered bitartrate of potassium, 76.

Saccharinum.—Heated in a glass tube, saccharin melts, darkens in colour, and gives off an odour of oil of bitter almonds. Heated with hydrate of calcium ammonium is evolved. If the residue, after igniting 0-1 grammes of saccharin with 0-5 grammes carbonate of sodium, is extracted with water, the filtrate acidified with nitric acid yields a white precipitate with nitrate of barium. A solution of saccharin in concentrated sulphuric acid assumes at most a pale yellow colour when heated in a water bath (test for sugar). Saccharin should not yield more than 1 per cent. of ash when ignited.

Syrupus Altheae.—Sliced marshmallow root, 1; cut liquorice root, 1; are washed with water and allowed to stand for two hours with 20 of water, and frequently stirred; press, strain, and boil with sugar 30.

Syropus Myrtilli.—Whortle berries are crushed, allowed to ferment, pressed and filtered; 2 parts of the juice are boiled with 3 of sugar.

Syropus Pectoralis (cough syrup).—Hyophos-
THE SOLUBILITY OF COAGULATED ALBUMIN IN
DILUTED HYDROCHLORIC ACID.

BY C. D. MOFFAT.

In a paper on the above subject, by Dr. Harding (Ph. J., II., 514) some statements were made which, being contrary to generally accepted notions, seemed to call for further investigation. The author—assuming as a fact that, when 200 grains of coagulated egg albumin is mixed with 2 fluid ounces of 0.2 per cent. hydrochloric acid and macerated at a temperature of 100° to 105° F. for five to six hours, 126 grains of the albumin is digested—comes to the conclusion that pepsin must play but a very small part in the digestion of albumin. In order to clear up this point a series of experiments was conducted on exactly similar lines. First, tests were carried out in which 25, 50, 100, and 125 grains respectively of coagulated egg albumin were mixed with 2 ccm. of acidulated water of the above strength and macerated on a water bath, the time being five hours and the temperature 100° to 104°. Further, the other conditions were most favourable for solution, the albumin having been twice passed through the sieve and triturated with the acidulated water. At the end of the time no apparent solution of albumin had taken place. The liquid decanted from the albumin was in each instance tested for syntonin by the customary reagents, such as ammonium sulphate, nitric acid, and the copper sulphate test, but no affirmative results were obtained.

Tests were then made with 200 grains and 1 grain respectively of albumin, mixed with the same quantity of acidulated water as before and macerated for six hours at a temperature of 100° to 104° F., a blank experiment being also carried out at the same time with 1 grain of albumin in distilled water. In the second and third case no solution of albumin was affected in either instance, but on filtering off the residue left from the 200 grains of albumin in the first instance, and evaporating the filtrate to dryness, a residue representing a solution of about 6 grains of albumin was obtained.

The only way in which it is possible to account for the extraordinary results mentioned in Dr. Harding’s paper is to suppose that his method of determining the solubility of the albumin was to weigh the residue of the maceration. This is obviously incorrect, owing to the variable amount of water contained in the coagulated egg albumin before and after maceration. If this plan be adopted the water must be determined in both cases, and allowance made for it.

As above mentioned, about 3 per cent. of albumin is dissolved when the acidulated water has a large quantity of albumin to work on, but when present only in small proportions solution is nil. It may be mentioned that the filtrate from the undissolved albumin gave all the reactions for syntonin when tested with the usual reagents.

METALS that are readily attacked by reagents are found by Dr. Meade Bolton (Inter. Med. Mag.) to exhibit a marked inhibitory action upon the growth of bacteria.
PHARMACOPEIA NORVEGICA.

At a moment when the issue of new pharmacoepias appears to be the order of the day, the publication of the third edition of the Norwegian Pharmacopoeia is not without interest. In one respect at least, viz., its size, the work offers an agreeable contrast to some of its bulky contemporaries, and suggests the vigorous application of the pruning knife in the revision of our own, which at present contains nearly double the number of preparations. The principal object of a pharmacopoeia may be assumed to be the definition of medicines, and the more accurately the medicines it contains are defined the more completely does the pharmacopoeia in this respect attain its object. But the definition of medicines should not be limited to tests of identity and purity; it should include a nomenclature of such a nature that both prescriber and dispenser may be protected from error, the former in the name by which he designates the preparation he wishes to administer, the latter in interpreting the intention of the prescriber.

Manufacturing processes for chemicals having been omitted from the Norwegian Pharmacopoeia, an increased stringency in the tests might reasonably be expected. Such, however, does not appear to be the case; only two drugs are required to yield when tested by specified methods minimum amounts of active principle, a limitation to be carefully distinguished from standardisation. Red cinchona bark should not yield less than 4 per cent. of total alkaloids, nor opium less than 10 per cent. of morphine. And for many highly active drugs the tests of identity and purity must be regarded as lamentably deficient. Several of the synthetic remedies have found a place in the work; amongst them may be noted acetanilide, antipyrin, phenacetin, saccharin, salol, sulphonal.

But the list of vegetable drugs appears somewhat meagre; of barks only seven are official; of roots and rhizomes, sixteen; of seeds and fruits, twenty. Much to be commended is the uniform strength and method of preparation of infusions and decoctions, by which useless repetition is avoided.

The nomenclature, however, can scarcely be regarded as satisfactory. Most dispensers will regard "cocaine hydrochlorae," "apomorphine hydrochlorae" as more satisfactory designations than "chloroetum oocacum," "chloroetum apomorphicum," in which the name of the more important constituent occupies the less conspicuous position. To the English pharmacist also the Norwegian Pharmacopoeia will probably appear generally behind the times. The definition of the medicines is lax; there is not a single attempt at standardisation, the nomenclature is an undesirable one, and although the book may contain here and there a feature worthy of consideration by those entrusted with the compilation of a pharmacopoeia, it has little claim to pose as a model of what a pharmacopoeia should be.

THE REDUCTION IN THE SPIRIT DUTY.

The announcement by the Chancellor of the Exchequer of the reduction in the spirit duty will be none the less welcome to chemists because it was expected. It was distinctly stated last year that the increase of sixpence per proof gallon was only intended to meet special exigencies, and that it would not be permanently enforced. This was also borne out by the Act under which it was imposed, and had it been intended to continue the increase it would have required re-enacting. Apart from the opposition which a continuance of the higher rate of duty would probably have provoked, there was no special inducement to lead Sir William Harcourt to alter his previously expressed determination. The extra sixpence was expected to yield a sum of nearly £750,000, whereas it only yielded some £200,000. In the opinion of the financial advisers there is every reason to believe that the increase of £200,000 in the revenue from the consumption of spirits would have been attained without the additional duty.

A similar instance occurred whilst Mr. Childers was Chancellor of the Exchequer. An increased duty on tobacco failed to yield the expected increase to the revenue, and the succeeding year when the duty was lowered again the consumption increased, and the Revenue returns were in consequence augmented to the desired extent. It is probable, therefore, that the conviction has forced itself upon the mind of the Chancellor of the Exchequer that 10s. 6d. per proof gallon is as much duty as spirits will conveniently bear, without a sensible decrease in the consumption. This
conclusion will be most satisfactory to those who feel that increase in the spirit duty falls unfairly on pharmacists.

It is not so generally known that the reduction in duty does not come into force until July, although the increased rate took effect from the evening of the 1884 Budget speech. The object of this was to enable the Revenue to collect the duty for twelve clear months. It was well known that large quantities of spirits were cleared out of bond just prior to last year's Budget in anticipation of an increase in the duty. It was hardly likely, however, that any dealer or manufacturer would clear as much as three months' consumption, so that the prolongation of the period of increased duty until July enables the Revenue to effect their object.

NATIVE PRODUCTS OF SIAM.

In the report of Mr. De Burgh to the Foreign Office, on the trade of Siam for the year 1893, it is pointed out that the greater part of the country being covered with dense jungle, the list of exports naturally includes an infinite variety of jungle products, such as the horns of buffalo and rhinoceros, benzoin, the hides, sinews, and horns of deer—all important items of the Chinese pharmacopoeia; stick-lac, edible birds' nests, cotton, mangrove bark, raw silk, armadillo skins, kingfishers' feathers, ivory, and gamboge. The most important and interesting are ivory, benzoin, stick-lac, and gamboge. The export of ivory was sixty-four piculs, or about four tons, valued at £17,772, or £2288. Of this sum seven-eighths went to Hong-Kong. Of benzoin, 319 piculs, or nearly 20 tons, figure in the export list, valued at £21,005, or £2,713. This valuable resin, it is pointed out, is also a product of the east bank of the Mekong, and is interesting as being confined to a narrow zone of forest-clad hill country to the east of Luang Prabang, lying between the 10th and 21st degrees of north latitude and longitude east 102 to 105. About three-fifths of the product reaches Bangkok by way of Nan, and the remainder by way of Nongkhai and Korat. The French occupation of Luang Prabang seems as yet to have caused no perceptible effect on the Bangkok export of benzoin beyond enhancing local prices, but with the completion of new roads already initiated by the French with a view to speedier communication between Luang Prabang and Tonquin, Bangkok exporters (chiefly British) are said to have well-founded fears lest the trade be diverted entirely from Bangkok to Hanoi. "The whole of the Bangkok export goes to the London market and then to France and Belgium to be manipulated into balsam. A small quantity is used locally for frankincense. Prices during 1893 were bad, first-class gum-benjamin fetching 125 ticals per picul (or about £1.16 per ton), and the second class, forty-five ticals per picul (about £1.40 per ton). The good quality known to buyers as 'bold blocky almonds' was scarce."

Gamboge is perhaps the most interesting of the Siamese native products. It is indigenous only in the islands and the sea coast of the Gulf of Siam lying between the 10th and 15th degrees of north latitude. The heavy rainfall of this coast appears to be necessary to the existence of the tree, which is known locally as "Ton Rong." It is found only in the islands of Koh Chang, Koh Kong, and Koh Rong, and on the mainland of the Indo-Chinese Peninsula opposite those islands. The trees grow to the height of some 50 feet, and are straight-stemmed with no lower branches, owing probably to the dense shade of the forest in which they grow. None of those seen by the Consul had a diameter of more than 12 inches. Ten years' growth is said to be required before the tree is ready for tapping. The Cambodian and Siamese islanders in the rainy months from June to October, when the sap is vigorous, cut a spiral line round the trunk from a height of some 10 feet downwards to the ground. The resin wells out of the bark and trickles down these grooves in a viscous stream, into a hollow bamboo placed at the base of the tree. From this it is decanted into smaller bamboo, where it is left for about a month to solidify. To effect removal, the bamboo is placed over a red-hot fire, and the husk cracking off. "Pipe" gamboge remains. The trees can be tapped two or three times during the season, and their trunks subsequently present a curious network of intersecting spirals. Care has to be taken to prevent the rain-water mixing with the resin in the grooves, as any mixture of water causes honey-combing and black discoloration, and a consequent depreciation of from 20 to 30 ticals (£3) per picul in value. "The most valuable gamboge is that which is the least honey-combed or discoloured, and is all the more difficult to obtain, considering the period of heavy rains during which the resin is extracted. The bamboo contain on an average rather less than 1 lb. of gamboge, or about 170 bamboo to the picul. The price asked by the pickers themselves is at the rate of 2 ticals (2a) for five bamboo full, and the local price is at the rate of 2 ticals (2a) for three, or 65 ticals (£4.18s.) per hundred, or about £8 7s. per picul. The whole output is sold to local Chinese traders and taken by sailing boat to Bangkok."

COMPLIMENTARY DINNER TO THE PRESIDENT OF THE NEW YORK COLLEGE OF PHARMACY.

The presence in London of Mr. S. W. Fairchild has been very agreeably made the opportunity for establishing a personal acquaintance between him and a number of British pharmacists, manufacturers, and others connected with the drug trade in London. With that object Mr. H. S. Willcox invited a large party to dinner on Tuesday evening at the Holborn Restaurant, the guests, including the President and Secretary of the Pharmaceutical Society, Mr. Ernest Hart, the Editor of the British Medical Journal, and several other medical men. Mr. Fairchild, who is a member of the firm of Fairchild Bros. & Foster, the manufacturing chemists of New York, is well known in connection with the production of digestive preparations, and has taken an active part in promoting pharmaceutical education at the College of which he is now the President. From the time that he and Mr. Willcox were pupils together at the Philadelphia College they have been more or less closely associated in business, and the compliment paid to Mr. Fairchild on this occasion by his old colleague must have been as gratifying to him as it was to those who had the pleasure of making his acquaintance and of sharing Mr. Willcox's hospitality.
EVENING MEETING IN EDINBURGH.

Friday, April 26, 1895.

MR. J. LAIDLAW SWING IN THE CHAIR.

(Concluded from page 975.)

The next communication read was on—

SMALLER-SIZED PHARMACOPOEIAL PILLS.

BY WILLIAM LYON.

At our February meeting, Dr. Stockman gave expression to the opinion that it would be an improvement, if, by leaving out some of the unimportant ingredients, the dose of the Pharmacopoeia pills could be reduced, as many people had great difficulty in swallowing one or two five-grain pills. Several other eminent authorities having expressed themselves similarly, it is our duty as pharmacists to consider how it can be done, and it was with the intention of initiating a discussion on the subject rather than of laying down definite formulae that experiments were made, the results of which are embodied in this paper.

In endeavouring to reduce the size of the pills several well-known and otherwise satisfactory exipients have to be set aside, as too large a bulk of them is required to give a satisfactory mass. Thus confection of roses, confection of hips, treacle, glycerin of tragacanth, and glucose are usually ineligible, and search has to be made for suitable substitutes. In the case of glycerin of tragacanth the objection is removed by increasing the quantity of glycerin 25 per cent. This modification of the B.P. formula gives a most useful exipient.

The disintegration test mentioned below was carried out as follows: One pill was put into a test tube along with two fluid drachms of water containing 32 per cent. of hydrochloric acid, the test tube placed in water (at 100°Fah.) and agitated at regular intervals. At the end of an hour, if the pill had not entirely disintegrated in that time, the residue was removed and examined. Whilst the foregoing cannot be said to afford any reliable criterion of what would take place in the stomach, still it is of some value as a comparative test.

For, Aloes Bark.—With nearly two and a half grains of aloes in each five-grain dose it is hardly to be expected that a small pill can be made. If, however, half a grain of aloin may be taken as therapeutically equal to two grains of aloes (the B.P. gives half a grain and two grains respectively as the minimum dose), a mass can be made every two grains of which are equal to five grains of B.P. mass.

The B.P. pill took twice as long as the others to disintegrate, it however had been kept for a somewhat longer time.

**Pill. Aloes et Asafetida.**—By reducing the quantity of soap and using liquid expipients the dose can be reduced to either four or three grains, and by using aloin in place of the aloe the dose is still further reduced to two grains.

III. was the only one completely disintegrated within an hour. The disintegration of the other three was only about half completed. Residues of these were fairly firm when pressed with the finger.

**Pill. Aloes et Ferri.**—Very likely objection will be made to the use of dried sulphate of iron owing to its reputed variable quality. That, however, is an objection easily dealt with. Dried sulphate of iron can be made to meet the Pharmacopoeia requirements, and pharmacist should insist upon it being made. By using the dried sulphate of iron and reducing the quantity of aromatic powder, the minimum dose can be reduced to three grains, or to two grains if the aromatic powder is still further reduced, and also used in place of aloes.

Mass gets somewhat crumbly on keeping, but when worked up in a mortar for a short time its plasticity returns, and it can be rolled out into pills without any difficulty. Pills keep the shape well.

Even more satisfactory.
III. Dried sulphate of iron .................. 10 .47 Like II., but it does not become so plastic
Aloin .................. 5 .25 25 when it is worked up in a mortar.
Compound powder of cinnamon.................. 15 .75 .75
Glycoerin of tragacanth (new) .................. 11
Or a sufficiency.
B.P., I and III. were almost completely disintegrated in an hour. II. only about half. The residues, however, very readily broke down when touched with the finger.

Pil. Aloe et Myrrh.—In order to retain the full quantities of the aloe and the myrrh, it is necessary to omit a portion of the saffron, but if aloin is used instead of aloes the full quantity of the saffron can be put in.

B.P.

\[
\begin{array}{lcl}
\text{Parts.} & \text{Approximate quantity in a pill} \\
\hline
\text{B.P.} & \\
\text{Soocotrine aloes in powder} & 3 & 1.6 \\
\text{Myrrh aloes in powder} & 1 & .8 \\
\text{Saffron, dried} & 5 & .4 \\
\text{Trecskle} & 1 & .5 \\
\text{Glycoerin (about)} & 1.5 & \\
\text{Total} & & 4.1 \\
\text{Dose, 5 to 10 grains.} & & \\
\end{array}
\]

I. Soocotrine aloes in powder .................. 12 .1.6 Good mass, though it gets rather hard when kept for some time.
Myrrh aloes in powder .................. 6 .3 \\
Saffron, dried .................. 1.5 .21 \\
Glycoerin .................. 3 \\
Syripur .................. 1 \\
Or a sufficiency.

II. Soocotrine aloes in powder .................. 12 .1.6 Mass very hard and flinty, can be reduced to fine powder with out difficulty. Pill looks beautiful.
Myrrh aloes in powder .................. 6 .3 \\
Hard soap .................. 1.5 \\
Glycoerin .................. 1 \\
Compound decoction of aloes .................. 1.5 \\
Or a sufficiency.

III. Aloin .................. 5 .25 .40 Pills and mass both brown and soft.
Myrrh in powder .................. 6 .3 \\
Saffron dried .................. 6 .5 .43 good. Keep nice and soft.
Glycoerin of tragacanth (new) .................. 3 \\
Or a sufficiency.

Neither of them completely disintegrated within an hour.

The residues of the B.P. I and II. were rather hard, III. quite soft.

Pil. Aloe Sooctr.—It is necessary to give formulæ here, for although the ingredients are present in the official pill in the same proportions as in pil. aloe Barb., owing to the oil of nutmeg being of a less adhesive nature than oil of caraway a larger quantity of a liquid excipient is required, and consequently the quantities of some of the other ingredients are altered.

B.P. Soocotrine aloes in powder .................. 16 2.4 \\
Hard soap in powder .................. 8 \\
Volatile oil of nutmeg .................. 1 .15 \\
Confection of roses .................. 8 \\
Dose, 5 to 10 grains.

I. Soocotrine aloes in powder .................. 8 2.4 \\
Hard soap in powder .................. 13 \\
Volatile oil of nutmeg .................. 3.5 1.6 \\
Compound decoction of aloes .................. 9 \\
Or a sufficiency.

II. Soocotrine aloes in powder .................. 14.5 2.4 \\
Hard soap in powder .................. 8.25 \\
Volatile oil of nutmeg .................. 1 .16 \\
Glycoerin of tragacanth (new) .................. 3 \\
Or a sufficiency.

III. Aloin .................. 5 .01 \\
Hard soap in powder .................. 7 \\
Volatile oil of nutmeg .................. 1 .15 \\
Compound decoction of aloes .................. 8 \\
Or a sufficiency.

Pil. Asafoetidae Co.—This pill is a difficult one to deal with. If the myrrh could be considered as non-essential, it would be somewhat easier reducing the size of the pill, but as it is present in the same proportion as the asafoetida and the galbanum, apparently it is a principal ingredient. The process detailed below gives a fairly good mass, and the dose would be two or four grains. Whilst it is very probable that pills made by this modification of the official formula would be as active as the official, that would have to be determined before the two could be compared.

B.P. Asafoetida .................. 2 1.4 \\
Galbanum .................. 2 1.4 \\
Myrrh .................. 2 1.4 \\
Trecskle .................. 1 \\
Dose, 5 to 10 grains.

I. Asafoetida .................. 30 \\
Galbanum .................. 30 \\
Myrrh .................. 30
Rub them in a mortar with successive portions of rectified spirit until all the soluble matter is removed. Strain the solution through flannel, evaporate on a water bath to a pilular consistence, add 30 per cent. of its weight of hard soap in powder, and mix thoroughly.

Glycerin was tried in place of the soap, but was not nearly so satisfactory.

Pill, Gamboge Co.—By reducing the quantities of soap and aromatic powder, the minimum dose can be reduced to three grains, and to two grains if aloin is used in place of aloe.

I. Gamboge in powder 10:75
Barbadoes aloe in
powder 10:75
Compound powder of
cinnamon 8
Hard soap in powder 6
Compound decoction of
aloe 2:5
Or a sufficiency

II. Gamboge in powder 11:75
Barbadoes aloe in
powder 11:75
Compound powder of
cinnamon 6:5
Hard soap in powder 6
Syrip 6
Or a sufficiency

III. Gamboge in powder 10:25
Aloin 3:75
Compound powder of
cinnamon 8
Hard soap in powder 6
Trece 10
Or a sufficiency

IV. Gamboge in powder 12:25
Aloin 3:25
Compound powder of
cinnamon 5:5
Hard soap in powder 6
Compound decoction of
aloe 2
Or a sufficiency

The residue of the latter was firm, the two former quite soft.

Pill, Colocyth Co.—If we have to keep to official galei-
cals it is impossible to reduce the dose of this pill below four grains. Allowed a free hand, however, a three-grain pill can be made by using a powdered extract of colocyth, prepared by macerating powdered colocyth in proof spirit for three days and then per-
oculating until exhausted, recovering the spirit by distil-
litation, and evaporating to dryness. One sample of colocyth thus treated yielded 22 per cent. of dry extractive. The activity of the extract has not yet been determined. That point, as well as the best method of preparing the extract, will be attended to later on when time permits.

I. Colocyth pulp in powder 3:75
Barbadoes aloe in
powder 8
Scammony resin in
powder 8
Sulphate of potas-
assium in powder 1
Oil of cloves 1
Water (about) 2
Or a sufficiency

II. Extract of colocyth in powder 8:25
Aloin 18:75
Resin of scammony in
powder 7:25
Curd soap in powder 21:75
Oil of cloves 8
Water 4
Or a sufficiency

Little or no disintegration had taken place at the end of an hour. The residues, however, were quite soft, especially II.

Pill, Colocyth et Aloe.—The percentage of extract of hanbore would be diminished, unless a powdered extract were made official.
PHARMACEUTICAL SOCIETY.

PHARMACUTICAL JOURNAL 1035

I. Compound pill of

B.P. Compound pill of colocynthis... 2
Extract of hembeae... 1

I 8 parts of Pil. colo. co. II minus water are equivalent to 3 parts pill. colo. co. B.P.

Good mass, but extracts vary so much that it is impossible to say that the same proportions would always make a good mass.

I. Extract of colocynthis in powder 0'25
Aloin... 0'1975
Resin from myrrh in powder... 0'75
Curd soap in powder... 0'2175
Oil of cloves... 0'3
Extract of hembeae 0'75

Pil. Hypoerg. —Dose can be reduced to two grains by using either confection of roses or manna, but there is no apparent advantage in using the latter.

B.P. Mercury... 3
Confection of roses... 3
Liquorice root in powder... 1

Dose, 3 to 8 grains.

I. Mercury... 103
Confection of roses... 63
Liquorice root in powder... 34

II. Mercury... 108
Manna... 96
Liquorice root in powder... 3

Pil. Ipecac. c. Scillae.—By using equivalent quantities of powdered opium and powdered ipecacuanha the dose can be reduced to two grains. The absence of the sulphate of potassium is not likely to make any difference in the action of the pill.

B.P. Compound powder of ipecacuanha... 3 2'1
Squill in powder... 1 '7
Ammonium in powder... 1 1
Treacle (abont)... 2
Dose, 6 to 10 grains.

I. Ipecacuanha in powder... 9 '80 good, and though
Opium in powder... 9 90 slightly harder than Sulphur in powder... 30 98 II., are nearer the correct strength.

Ammonium in powder... 30 98
Liquid Extract of liquorice... 10
Or a sufficiency.

II. Ipecacuanha in powder... 9 '19 good, but inclined to
Opium in powder... 9 9 19 be sticky.
Squill in powder... 30 94
Ammonium in powder... 30 94
Syrup... 15
Or a sufficiency.

The B.P. pill disintegrates quicker than either I. or II., but both of the latter were almost completely disinte- grated at the end of an hour. The residues were quite soft.

Pil. Plumbi c. Opia.—It is neither possible nor necessary to reduce the dose of this pill. A better exception, however, might be found in syrup, only it makes the pill slightly stronger.

B.P. Acetate of lead in powder... 6 3
Opium in powder... 1 37
Confection of roses... 1
Dose, 8 to 10 grains.

I. Acetate of lead in powder... 6 3
Opium in powder... 1 39
Syrup... 4
Or a sufficiency.

I. Disintegrates sooner than the B.P. pill.

Pil. Rhei C.—There are several methods of reducing the size of this pill, and not much difference in the results. That which necessitates the least possible change from the official formula is likely to be the most acceptable.

B.P. Rhubarb root in powder... 6 12
Sooctrine aloe in powder... 4 5
Myrrh in powder... 3
Hard soap in powder... 3
Oil of peppermint... 3 6
Glycerin... 2
Treacle... 6
Dose, 6 to 10 grains.

I. Rhubarb root in powder... 34 1 8 Mass and pills both
Sooctrine aloe in powder... 18 9 good.
Hard soap in powder... 8 6
Oil of peppermint... 1 05
Glycerin... 3
Syrup... 3
Or a sufficiency.

II. Extract of rhubarb... 8 9 Mass and pills both
Sooctrine aloe in powder... 18 9 good, but not better than 1.
Myrrh in powder... 9
Hard soap in powder... 1 05
Oil of peppermint... 1
Glycerin... 2
Syrup... 3
Or a sufficiency.

* Good rhubarb root is said to yield about 35 per cent. of B.P. extract, or 90 per cent. of dry extract.
### Pil. Scammon. Co.—Cannot very readily be made into less than 4-grain pills. Jalapin and scammonin would scarcely be admitted as eligible substitutes.

<table>
<thead>
<tr>
<th>Parta.</th>
<th>Approximate in a 4-grain pill.</th>

PHARMACEUTICAL SOCIETY.

Of the remaining pills, pil. phosphori may be passed over, as the dose is small enough already, pil. conti co., pil. ferri carb., pil. hyd. subchlor. co. do not lend themselves readily to reduction, and pil. ferri iodid, and pil. ferri are being investigated and will be reported on next session.

The next communication was a

NOTE ON COMMERCIAL LINSEEDS.

BY A. J. DEXT and W. R. COWIE.

One of the results of the communication read by one of us at the last evening meeting (ante, p. 899) has been the donation to the Museum of specimens of the various commercial linseeds as found in the market at the present time. These have been handed to us by Mr. Hill in the belief that a report upon them would be a useful and interesting communication to this meeting.

The comparative size and weight of the different varieties of seed is readily seen by the following figures, obtained by weighing 50 grains of each sample and counting the number of seeds in each. The largest seeds are placed first in order and the smallest last.

South American...... 466 seeds weigh 50 grains.
Bombay .............. 485      "  "      "
Turkish .............. 542      "  "      "
Canadian ............. 484      "  "      "
Dutch .............. 692      "  "      "
Russian ............. 754      "  "      "
English ............. 823      "  "      "

The Russian sample contained about 1-5 per cent. of foreign seeds, including a considerable proportion of cruciferous seeds; the Canadian sample contained about 0-7 per cent. of foreign seeds, including a few apparently grass seeds; and a few cruciferous seeds were seen in the Turkish sample. The South American sample contained a quantity of whitish quartz-like fairly large-sized fragments of stone; the Turkish sample contained some reddish coloured sandy matter; and the Bombay sample contained small fragments of blackish, friable earthy matter. None of the samples gave a perceptible pungent odour indicative of cruciferous seeds, and as these were undoubtedly present in at least two samples, it would appear that the test is not sufficiently delicate for the detection of so small a percentage. Probably, however, it is sufficient to detect such a percentage as would unfit the meal for medicinal use. Greenish mentions that it may sometimes reach 30 per cent. The cooled decoction of the English and Turkish samples formed a very thick mucilaginous geyee mass, indicating a relatively high percentage of gum. The samples were examined for starch and the percentage of oil and of ash. The results are shown by the following table. Sicilian linseed is not at present met with in the market, its excess of husk is said to be against its use.

The above shows an average of 36-87 per cent. of oil and 2-87 per cent. of ash. In view of this percentage of ash we suggest that the standard maximum ash to be permitted for linseed meal should be 5 per cent. instead of 6 per cent., as suggested by one of us at last meeting. Mr. Greenish in 1871 (‘Year-Book,’ 1871, p. 596) states that linseed contains 25 to 30 per cent. of oil, and in a subsequent paper (‘Year-Book,’ 1884, p. 470) he gives it as 30 to 33 per cent. Our results indicate that 34 to 40 per cent. is nearer the actual figures. The sample of English linseed consisted of much smaller seeds than any of the others, and it will be observed that its percentage of oil, 29-6, excludes it from our suggested standard, 30 per cent., as an official source of linseed meal. Greenish mentions that it is not employed by linseed crushers. The seeds looked immature, and though the cooled decoction did not give a blue starch reaction, a faint purple colour was produced on the addition of the iodine, indicating, probably, the presence of some partially altered starch in some immature seeds. The starch reaction in the Canadian sample was distinct though slight, and very distinct in the Russian sample. These contained 0-7 and 1-5 per cent. of foreign seeds respectively, which seem to have been the source of the starch. The ash of the South American sample was very white; that of the Turkish reddish; and that of the Bombay black, due no doubt to the quartz-like fragments, reddish sandy matter, and blackish, friable earthy matter already noted as being found in these samples respectively.

With the exception of the stone and earthy matters already noted, the South American and Bombay seeds were large-sized, of excellent quality, very free from foreign seeds, highly farinaeous, and yielding a high percentage of oil.

The last communication was on—

THE LEGALISATION OF THE METRIC WEIGHTS AND MEASURES.

BY GEORGE LUNAN.

The question of the legalisation of metric weights and measures becomes more urgent in view of suggestions to increase present use of system, or adopt in toto in new B.P.

Mr. Umney, on behalf of the London Chamber of Commerce and Drug Club, wrote the Pharmaceutical Council in January, pointing out that a grievance existed from it being unlawful to weigh or measure by this system when wholesale druggists received orders from foreign countries where latter only is used; and the Council agreed to recommend the amendment of Weights and Measures Acts, 1878, and 1889, so as to legalise the metric weights and measures for export trade purposes only (Act to amend the Weights and Measures Acts, 1878 and 1895, see page 588, Ph. J., No. 1281). The Weights and
Measures Act, 1878, gives a table of equivalents (Third Schedule, Part I.), and clause 18 states that "such table may be lawfully used for computing and expressing, in weights and measures, weights and measures of the metric system." From that, it need not be doubted that it is illegal to use metric weights and measures for purposes of commerce. The question of legalising the system is surrounded with difficulties, even though we are agreed that its principle is scientific, its use simple, and its increasing recognition compels us to believe that it must ultimately be adopted. It will be difficult to obtain legal power, specially for weights and measures for the purposes of dispensing, without at the same time legalising for general use, and this will call forth strong opposition. Without legal authority for actual weights not equivalents in grains, etc., we cannot put processes for quantitative estimations in B.P.—a very desirable improvement—in metric weights and measures. The maximum dose in metric equivalent could be stated if it were legal to use the weights and measures, were it not that an alternative dose would involve at least three or four figures to fairly express present equivalents.

It would be an advance, and would lead to greater familiarity with metric weights and measures if the system could be legalised for the purposes of the quantitative estimations, and that at present is as much as we can expect to be done by the compilers of the new Pharmacopoeia.

The discussion on the three preceding papers was taken together.

Mr. Dorr said he did not think aloin could be quite easily taken as a substitute for aloes, as the equivalent of the one to the other had not yet been clearly established. He thought also that in many cases a smaller dose of aloes would be sufficient, and if anyone wished to take a larger dose it was a simple matter to take two pills.

Mr. Mackenzie said he thought this paper was a step in the right direction. Those engaged in dispensing knew that the use of aloes was an effectual means of removing the objection to aloes, namely, its offensive taste and smell. He was not sure that he agreed with all that had been said, but he thought there was a decided tendency nowadays to greatly reduce the size of all pills.

Mr. Henry said, considering what had recently been said about polypharmacy, it was a question whether aloin would be accepted. This paper was a very useful one indeed, and should receive the careful attention of those who were to deal with this matter. He was not in favour of the formula for pill. asafetida co., for it could not be conducted in an ordinary pharmacy without a fumes chamber. He had also found that the use of syrup as an excipient had a tendency to cause pitting of the pills.

Mr. Lunan said there were some objections to the use of very small pills, and related the case of a lady who professed to obtain great benefit from a small liver pill, which was found next day in her false teeth. No doubt the tendency now was to elegance in pharmacy, but they should not forget that there were objections to very small-sized pills. They might get lost, and sometimes contained very potent medicines such as strychnine.

Mr. Rutherford Hill said he had gone carefully over this paper on pills, and the work had all been very carefully done, and well deserved attention.

Mr. Coull said he thought one objection to the proposed formula for pil. asafetidae co. was the evaporation of the alcoholic solution, which would cause loss of the active constituent, volatile oil.

Mr. Henry said, with reference to the note on linseeds, he had that day examined his own stock, and found that 288 seeds weighed 50 grains. Evidently they were much larger than any of the samples reported on, but he did not know the source of them.

Mr. MacLaren said Mr. Lunan had raised the question about weights and measures, but he did not gather that he had any proposal of his own to make. He noticed that in price-lists certain goods were frequently quoted in metric weights, and if that was not legal the attention of the parties doing so should be drawn to it.

Mr. Forret said he had been unable to follow Mr. Lunan. At present they could use metric weights in volumetric analysis, and he did not see why he spoke of legalising their use.

Mr. Mackenzie said he thought they were not yet by any means ready for a general adoption of these French weights and measures in ordinary commerce in this country.

Mr. Dorr said there were two distinct questions raised, namely, the compulsory use of these weights and measures, and the legalising of their use in the manner suggested by Umney and others. They could not, for instance, weigh out for sale a kilogramme of any article, but they could use the equivalent of a kilogramme in imperial weights. With regard to the difficulty of giving the equivalent of doses in the metric system, it was not necessary to have the exact equivalent, as suggested by Mr. Lunan, and it was not necessary to have two or three decimal figures.

Mr. Hill said it was proposed by Mr. Umney and others that the use of metric weights and measures should be made legal for export trade, so as to enable exporters to execute certain orders from foreign countries. Just now no one could legally sell by retail a gramme of sulphate of quinine or a litre of, say, turpentine. He understood Mr. Lunan’s suggestion in this direction to be the general legalisation of these weights for all trade purposes, and not merely for export. It was not a compulsory use, but merely a permissive power, that was asked, and he saw no objection to that being granted.

Mr. Lyon, in reply, said if the quantity of aloin he suggested was too large, it could easily be altered. The question as to the equivalence of aloin and aloes was for the medicals to settle; as to the formula for pil. asafetidae co., he would point out that the present formula was open to the same objection as the ingredients were ordered to be treated with treacle till liquefied. He had not found that pills made with syrup pitted.
Mr. Lunan, in reply, said he wished the new Pharmacopoeia to contain the metric system for the making of official tests, and he did not think that could be done till it was legalised. He did not see why the grain system should have the premier place in the Pharmacopoeia. It was quite true that at present we cannot sell anything by retail by using the metric weights. The difficulty about equivalents would be seen if the dose ran up to, say, one ounce, which would be equal to 28-287 grammes.

On the motion of the Chairman, a cordial vote of thanks was awarded to the authors of papers.

The Assistant-Secretary said, by the kindness of Mr. W. W. Ainslie, 68, George Street, he was enabled to show to the meeting the original parchment Burgess and Guild Ticket of James Gardner, apothecary, dated October 5, 1786, and also the original parchment Burgess Ticket of his son, James Gardner, also designated apothecary, dated May 27, 1825. He also directed attention to some donations to the Museum, and a vote of thanks having been awarded to the donors, the meeting closed.

Proceedings of Societies in London.

CHEMISTS’ ASSISTANTS’ ASSOCIATION.

At the meeting of this Association on April 25, the following paper was communicated:—

ESSENTIAL OILS IN THEIR RELATION TO THE BRITISH PHARMACOPEIA AND TRADE.

BY JOHN G. UMNEY.

(Concluded from page 981.)

Nutmeg Oil.—The results of a comparison of foreign and English oils of nutmeg have recently been published in the Ph. J. [3], xxiv., 985, and a sample adulterated with a hydrocarbon oil reported on. The principal pharmaceutical use of this oil being for the production of sal volatile, it is highly important that the oil should be readily soluble in spirit. The English and pure foreign oils examined were found to be soluble in their own volume of alcohol of 94 per cent., and to show but slight variation in specific gravity, and the percentages boiling below 180° C., which were about 60 per cent. It seems desirable to call attention to one feature of the English oil there reported on which has also been observed in other unrectified samples, namely, the presence of a considerable proportion of fixed oil which doubtless passes over in distillation and is not removed by rectification. This concrete oil may be readily identified by separation and purification of the residue of fractional distillation of the oil, or by evaporation on a water bath; myristic acid, of which it principally consists, being recognised by the m.p. (64° C.). The presence of this body appears to cause, moreover, an unpleasant preponderance of the nutmeg over the lemon flavour in sal volatile, and hence should be carefully avoided. The optical rotations vary within narrow limits, the lowest being +16°-25 in the case of an English oil, and the highest +23°-25 in the case of a foreign oil, which was pure and answered all the required tests.

It is suggested that in the new pharmacopoeia the words “distilled in Britain” be omitted and the following characters and tests be included:—

Specific gravity.—870 to 910 at 15° C.

Optical rotation from +15 to +25 in a tube of 100 Mm.

Soluble in an equal volume of a mixture of equal parts rectified spirits and absolute alcohol.

Absence of fixed oil.—The oil should not leave a crystalline residue when evaporated on a water bath.

Orange Oils.—The United States Pharmacopoeia (1890) has made official, under the name of oil auranti in fortis, the oils of both sweet (Citrus aurantium) and bitter orange (Citrus vulgaris). The British Pharmacopoeia Conference formulary has also included for some years the oil of bitter orange for the preparation of elixir simplex. As it is by no means improbable that this preparation and others of the same type may be made official in the new British Pharmacopoeia, it seems desirable to define as precisely as possible which variety of oil shall be employed, since the odours of the two oils when unmixed are sufficiently different as to make distinction possible between an elixir prepared with the oils of the sweet and bitter variety respectively.

The specific gravities of the oils show but slight variation from the statement of the United States Pharmacopoeia, viz., about 860 at 15° C., being from 848 to 856, but the optical rotation of a genuine oil of bitter orange, according to Schimmel and Co., may fall below +90°, the lowest limit fixed by the U.S.P. for the two oils, though this requirement is easily complied with as regards the sweet orange oil, which varies between 95° and 99° in 100 Mm. tube.

Should it be thought desirable to include one of the oils in the new British Pharmacopoeia it would be preferable that it should be that of the bitter orange, which has been used during the past few years in this country in the pharmaceutical preparations already referred to.

A sample of pure oil, which has been examined, was found to have a specific gravity of 8551 at 15° C., to have a rotation of +97°-79° in a tube of 100 Mm.

Its comparison with a sample of adulterated oil, which had a specific gravity 8568, a rotation of +74° is shown in the following table, but it is extremely difficult to frame characters and tests that will exclude for certainty the oil of the sweet variety.

Bitter Orange Oils.

The following are suggested as the most desirable requirements for oil aurantii amarae, obtained by expression from the fresh peel of Citrus vulgaris. Specific gravity.—848 to 856 at 15° C.

Rotation.—Not less than +92 in a tube of 100 Mm.

Peppermint Oil.—Although the “English distilled” oil of peppermint is the only kind recognised by the British Pharmacopoeia for pharmaceutical purposes, yet several other varieties play an important part in the commerce of this article, and have in consequence definite and considerable value.

The English, German and American distillates are the produce of Mentha piperita, whilst the Japanese

American Peppermint Oils.—These oils vary in price, which is gauged according to their aroma, freedom from contamination with the oils of other Labiates, viz., spearmint, etc., being specially sought after.

The determination of the menthol percentage of these oils is not of great value, although in some of the Inferior American oils it has been as low as 24 per cent., probably through partial demethylation.

The following samples, selected from very many examined, indicate average commercial samples of the Wayne county oil, from which district large imports reach England annually, and last year particularly so, as the crop was unusually large.

The English oils, the greater part of which are distilled in the districts of Mitcham, Surrey, in Cambridgeshire, Lincolnshire, and Hertfordshire, show only the slightest variations, and possess, when not rectified, a specific gravity of from 900—910 at 15° C.

The superior aroma of these oils, notwithstanding their power and pungency are directly due to the proportions of menthol they contain, appears to depend upon esters and aldehydes present in varying proportion in the oil, the actual menthol percentage one of secondary value. The proportion of free menthol present in these oils varies from 55 to 65 per cent.

It may be that the menthol present in the English oils is an isomeric modification of that found in Japanese and American oils, as experiment shows that the menthol crystallises far less readily from a sample of English than from these oils, although the percentages of free menthol indicated by the acetylation and saponification process already mentioned be identical.*

* This observation is noted by Schimmel and Co. in their report (April, 1895) issued since this paper was written. They go further and suggest, however, that the superior aroma of English oil may be dependent on this modification of menthol, rather than to a variation in the relative proportions of the various esters present.

* This observation is noted by Schimmel and Co. in their report (April, 1895) issued since this paper was written. They go further and suggest, however, that the superior aroma of English oil may be dependent on this modification of menthol, rather than to a variation in the relative proportions of the various esters present.
As it is doubtful whether the determination of menthol alone throws any direct light on the aroma value of the English oils, it is suggested that in the case of this oil (as well as that of lavender) the words " distilled in Britain " be retained in the new edition of the British Pharmacopoeia, the characters and tests being amplified somewhat as under:

Specific gravity at 15° C. -900 -910.
Optical rotation. -25 to -32 in a tube of 100 Mm. Not less than 50 per cent. should distill between 210°-260° C.

Pimento Oil. - This oil is official in the United States Pharmacopoeia, as well as the British Pharmacopoeia of 1885, notwithstanding its close relationship to oil of cloves, which also finds a place in both those works. The oil is imported into this country from Jamaica in fairly large quantity, and not withstanding the official requirement that it should be " distilled in Britain," is largely used for flavouring purposes. Examination of many samples of this imported oil have led to the belief that it is of excellent quality, and a recent comparison of a sample with a sample of English distillation is in favour of the foreign oil. The specific gravities of all the samples stand between 1.040 and 1.050 at 15° C., with the exception of one sample of German distillation, which possessed a specific gravity of only 0.985, and differed so much in other respects as to make its character worth recording. The United States Pharmacopoeia in requiring a specific gravity of from 1.045 to 1.055, places the lower limit somewhat too high, as the eugenol-content of several English oils of lower specific gravity is highly satisfactory, the characters of a typical one of which are detailed below.

The amount of eugenol present in this oil has been variously stated at from 33 per cent. (Oswar), to 70 per cent. (Stohmann). Estimations of this body by Thom's benzoyl-chloride process, already mentioned (see oil of cloves), indicate 65 to 70 per cent. of eugenol, but even this proportion is lower than the specific gravity would appear to indicate.

The proportion of eugenol found by the alkali process does not agree so closely with the calculated amounts as in the case of oil of cloves, due apparently to the presence of resin and possibly small quantities of other bodies present in the oil.

The following are the percentages of eugenol determined by this process, together with those obtained by the benzoyl-chloride process.

Pinus sylvestris Oil. - This oil, which is not official in either the United States or German Pharmacopoeias, is one employed in fair quantity, although principally for inhalation and external use in this country, and finds a place in one medicinal Pharmacopoeia, a minimum specific gravity of 0.870 at 15° C. being required.

This single character is one which is not easily complied with, the greatest diversity existing in the oils met with in trade, which appear to be the products of various species of Pinus and Abies, frequently, moreover, more or less mixed with oil of turpentine.

The characters of the oils distilled from the principal species of Pinus and Abies have been made the subject of a careful investigation in the laboratory of Schimmel and Co., the oil distilled by this firm from true Pinus sylvestris having a specific gravity of 0.886 at 15° C., and a rotation of +10°.

I have been unsuccessful in obtaining an oil to answer these characters, the nearest approach to it being the oil sold under the registered title " fir-wool " oil. A sample of this recently examined had a specific gravity of 0.886 at 15° C., and

| Sp. gr. Eugenol by Eugenol by |

The optical rotations of all the samples examined vary from -1 to -3 in 100 Mm., with the exception of the light German oil already noticed, which had a rotation of -3.75. The following appear, therefore, to be the principal characters of pure oil, and might be thus incorporated in a new S. F. I. if its retention in that work be decided upon:

Specific gravity. - Not below 1.040 at 15° C.
Optical rotation. - Not more than -4.

When treated with solution of caustic potash (as described under clove oil) not more than 5 per cent. should remain combined, equal to about 75 per cent. eugenol. Not more than 40 per cent. should distill below 247° C.
a rotation of +13.26° in a 100 Mm. tube. All the oils I have obtained from the Tyrol and Switzerland, where they are almost entirely distilled, are levorotatory and of much lower specific gravity. Their rotations vary between -60 and -70 in 100 Mm. tubes; the gravities of some were as low as 0.85 at 15°C. These characters agree with those ascribed to the oil of the young cones of Abies saccata, their probable identity being corroborated by their high percentage of limonene, as shown by fractionation. The odour of the fine oils is stated to be due to borneyl acetate, the percentage of this varying from 8 to 18 per cent. in the oil of Pinus pseudotsuga, down to about 1 to 2 per cent. in the oils already described as being those usually met with in commerce. This ester may be readily estimated by the saponification process described under bergamot and lavender oils, and is a useful factor for the determination of the value of the oil apart from its physical characters.

Fractionation indicates that the commercial oils contain large proportions of limonene, the "furfur" oil being no exception, although it differs from the others in containing a preponderance of dextro-limonene.

The pure oil distilled by Schimmel and Co., from true rose oil, contained only 6.5 per cent. of borneyl acetate, pinene and borneyl acetate, a sesquiterpene in the highest fractions, which is absent in these other oils. Two grossly adulterated samples are included in the appended table, one consisting of turpentine with a small percentage of acetate ether, the other consisting almost exclusively of turpentine.

It is imperative, therefore, that if this oil be retained in a new B.P., its characters shall be so strictly defined as to necessitate an oil of constant composition being employed in pharmacy, of which the medicinal value, if any, may be determined. An investigation of the relative quantities of the oils of Pinus pseudotsuga and Pinus sylvestris would be interesting and would probably result in the inclusion of the former oil only in a new British Pharmacopoeia. The samples of Pinus sylvestris that I have examined have been fairly constant in characters, two being included in a table appended. Such attention is called to the percentage of boreyl acetate, vis., 5.6 and 6.3 respectively contained in them.

Rose Oil.—The variations in essential oils, due to differences in climate and soil (which have been already referred to in the case of lavender and particular species of lavender), are marked in the case of rose oil than in any other instance. The difference in the fusing points of oils distilled in different districts, as well as the proportions of stearopten contained in them, formed part of an interesting paper (Ph. Jap., xviii, 504) by D. Hambury in 1865. The paper was published in the 16th to 18th C. in the case of Turkish rose oil, to 36°C to 43°C in the case of English distilled oils (obtained, it should be noted, however, in the distillation of rose water). The percentage of stearopten obtained under precisely identical conditions varied from 6 and 7 per cent. in the case of Turkish rose oil, to 68 per cent. obtained from the English oil prepared under the conditions already referred to. Filkinger subsequently ('Y. B.', 1885, p. 210) recorded 92 and 28 as the proportions of stearopten in samples of Turkish and German oil respectively. The observation on the nature of the stearopten from rose oil by Schimmel and Co., who state that they have separated two hydrocarbons melting at 41° and 22° respectively, suggested to me that varying proportions of these two and possibly other homologous hydrocarbons might cause variation in the melting point of the oils, apart from the actual percentage of stearopten present.

The difference in the fusing points of the samples of German and Turkish oils was so great as to

make this matter worthy of experiment. 5 grammes of No. 2 (Turkish), No. 4 (German) were treated under precisely similar conditions with 32 C.C. of rectified spirit at 15°C in successive portions, and yielded 43 and 69 per cent. of stearopten respectively. The stearopten were carefully dried at 100°C, and were found to melt at the same temperature, viz., about 33°C. The strength of the odour of the oil is diminished in proportion to the stearopten present, and it is imperative therefore that in those districts where the conditions of climate and soil or manufacture cause such increase that the oil should be freed from objectionable feature.

I have tabulated the melting point of these samples, together with those of other well-known brands of Turkish oil of rose. It will be noted in that table that the specific gravities at 20°C of the four samples of Turkish oil differ but slightly, whilst that of the German sample is lower and below that admitted by the United States Pharmacopoeia, viz., from -865 to -880 at 20°C.

The specific gravity of geraniol is between -881 and -883 at 15°C, whilst the specific gravity of the stearopten separated from the above oils was found to be between -860 and -864 at 15°C. It may be noted that French, Algerian and Turkish geranium oils are levorotatory, samples of each kind examined giving the following results in a 100 Mm. tube:

<table>

</tbody>
</table>

The chemistry of oil of rose must of necessity be considered undecided until the composition of the alcohol, which is its principal constituent, is determined. It is stated by Markownikoff and Reformatsky to be roselo (C19H20O), in opposition to Bertram and Gildeimann, who hold the view that it is geranial (C19H20O). It is identical with that as obtained from melargoum and andropogon oils.

The latter view was adopted as the result of a chemical examination of Turkish and German rose oils, but Markownikoff and Reformatsky, whose experiments were made on samples submitted by the Bulgarian Government, now state that roselo does not exist in pure Turkish otto of rose, the presence of it in the oil examined by the German chemists indicating geranium-adulterated oil. The fact that geraniol forms a stable compound with chloride of calcium, easily decomposed by water, renders the separation of that body comparatively easy, and the difference between the formula ascribed to rosol and geraniol is so small as to make it difficult by combustion alone to decide which is the more appropriate. The physical characters will, therefore, need careful comparison to ascertain whether any difference exists.

These results are quite sufficient to indicate that at present no conclusive chemical test for the presence of geranium oil in oil of roses can exist, and the result of a comparison by the United States Pharmacopoeia test for that oil on three well-known brands of Turkish oil of rose, one of German distillation, and samples of commercial artificial otios are included

* Certain slight differences are recorded and commented on in the half-yearly report of Schimmel and Co., just to hand (April, 1886), in the boiling points of geranyl and so-called rosol, as well as in the melting point of their acetates.
in the table. The test consists in adding five drops of concentrated sulphuric acid to five drops of the oil, and then shaking with 2 C.c. of alcohol, when the liquid should not at once assume a red or reddish-brown colour.

In view of the desirability of fixing standards of purity for the oils most largely employed in pharmacy, though of no medicinal value, it is suggested that this oil be included in a new British Pharmacopoeia, although tests for its purity and freedom from oils of geranium, etc., cannot be framed at present. The following two characters appear to be those of the purest oils of Turkish distillation met with in trade:—

Specific gravity at 20° C. — 860 to 870.  
Melting point. — From 19 to 22° C.

### Rosemary Oil.

The purity of oil of rosemary is a subject which has led to considerable controversy, and the passage of arms between Cripps and Schimmel and Co. will doubtless be fresh in the memory of those who follow closely the history of essential oils. The reason of that divergence of opinion appears to have arisen, in part, at any rate, through the fact that the former examined and commented on samples of English rosemary oils with one exception, whilst those reported on by the latter were either Italian or French or distilled by themselves from flowers and leaves from those countries.

The English oils examined by Cripps had a specific gravity of 0901 to 0924 at 15° C., whilst the genuine French and Italian examined by Schimmel varied between 0901 and 0907 at 15° C. The oil distilled by Schimmel and Co. from dried French flowers, had a specific gravity of 0920 at 15° C., although they add, in reporting thereon, “if fresh material could be obtained for use, as would probably be the case with the oils of commerce, the specific gravity of the oil would come out somewhat lower. The specific gravity of the United States Pharmacopoeia is 0985 to 0915 at 15° C., and the German Pharmacopoeia 0989 to 0991.

The solubility of the oil in rectified spirits is a reliable test for the absence of turpentine, a pure oil dissolving in less than twice its volume of alcohol of that strength.

The pure oils examined were slightly dextrorotatory, whilst the impure oils in which the adulterant was French oil of turpentine, were levorotatory in proportion to the extent of their sophistication.

The percentage of borneol in this oil, which boils at 203 to 204° C., may be approximately determined by fractionation, but the saponification process, to which reference have been made under bermamot, admits of the exact estimation of the body, and affords indirects of the purity or otherwise of the oil. The finest oils contain from 11 to 15 per cent. whilst the adulterated samples examined contained only from 7 to 8 per cent.*

The results of the comparison of an English (Lincolnshire) distilled sample with foreign oils of various degrees of purity appear in the following table:

During fractionation of the English sample the borneol crystallised in the condenser, but this was not observed either in the Spanish or any of the French oils.

The characters of pure rosemary oil appear, therefore, to be as under:—

Specific gravity. — 0900 to 0920 at 15° C.

* The examination of the Spanish oil showed the presence of 25-6 per cent. of borneol, whilst by fractionation important differences were found between it and pure rosemary oils of truer than 23 per cent. borneol. A sample of Spanish oil of sage obtained from the same distiller examined was found to have a specific gravity of 0924 at 15° C., and to yield 59-13 per cent. of an alcohol, probably “salvollar,” by the saponification process, its admixture with that oil seems highly probable.

* Probable mixed with “sage” oil.
to be the produce of one of the Rutaceae stated to have been imported from Venezuela. A sample of Fiji oil distilled in my firm's laboratory was subsequently reported on by McEwan (Ph. J., xvii., 681), who found it to have a specific gravity of 0.9788 at 16° C., and a rotation of -25° in a tube of 100 Mm.

The high specific gravity of a sample of Indian oil, viz., 0.9866, is also commented on, prolonged heating in the process of manufacture being the reason assigned for such peculiarity. The lowering of specific gravity by the addition of cedar wood oil is also referred to by Holmes (ibid.), and Cryppes has also called attention to other features, viz., solubility in alcohol and colour reactions for the detection of cedar wood oil in sandal oil.

In order to ascertain how far the oils met with in trade agree with these characters I have made a careful comparison of the chief commercial varieties both of English and foreign distillation. The specific gravities of the oils distilled from East Indian and Macassar wood vary between 0.975 to 0.980 at 15° C., and do not indicate the presence of cedar wood oil; the samples of this oil examined varying between 0.937 to 0.950 at 15° C. I have included in a comparative table appended the principal characters of a sample of this oil, which had a specific gravity of 0.9866.

I have also examined samples of Australian and West Indian sandal oil, which possessed specific gravity of 0.9655 and 0.9623 respectively, and have included them in a comparative table. The optical rotation of the East Indian and Macassar oils, both of English and German distillation, varies between -17° and -20°, whilst the cedar oils examined, one was levo, rotary to the extent of -38° 25', though that appears to be somewhat abnormal. The West Indian and Australian varieties are both dextrorotatory, this character being noted in the United States Pharmacopoeia to preclude their use. The sample of West Indian had a rotation of +25° 75', and the Australian +35° 25' in a 100 Mm. tube. The fractionation of the oils is attended with some difficulty at ordinary atmospheric pressure, but the results obtained are interesting as showing the range of boiling of the various varieties of oil as compared also with that of a sample of cedar wood oil.

The solubility of the oil in alcohol of various strengths has been proposed as an additional test for the purity of this oil, Holmes having suggested soluble in equal volume alcohol, specific gravity 0.920, and Crippes stating that it should be soluble in 3 times volume alcohol (about 75 per cent. by volume) at 15°-5° C.

Schimmel and Co. suggest a solubility in 5 volumes alcohol, 70 per cent. at 20° C.
The U.S. Pharmacopeia, that one part of the oil shall form a clear solution with 10 volumes of alcohol of 70 per cent. (volume) at 20° C.

Most all the pure oils examined dissolve in 5 to 6 volumes of alcohol of 70 per cent. (volume) strength at 20° C., and it seems that that requirement is not too stringent.

The following may be summarised as the principal characters and tests of a pure East Indian (or Macassar) oil. (The quantity of West Indian, Australian, and other oils imported is so small as to be of little importance, although there is no reason for supposing that their therapeutic action differs to any great extent from that of the first-named.)

Specific gravity.—Not below 0.975 at 15° C.

Optical rotation.—Not less than 16°, and not more than 20°.

The greater portion distills between 275° C. and 295° C. One part of the oil should dissolve in 6 parts of alcohol of 70 per cent. by volume at 20° C.

**Savin Oil.**—This oil, which, like that of rue, is so little used as to warrant its exclusion from a future pharmacopeia, contains the sesquiterpene cadinenes in common with oil of juniper berries, as well as pinene and other undetermined bodies to which the powerful action of the oil is probably due.

An oil distilled in Britain, which is alone official in the B.P., 1885, recently examined, had a special gravity of 0.934 at 15° C.

The rotation of this oil was +43.5° in a tube of 100 Mm., which agrees fairly well with that obtained by Flückiger on a sample distilled from fresh plant cultivated at Mitcham.

It yielded on fractionation the following percentages:

<table>
<thead>

</tbody>
</table>

A considerable quantity of a polyterpene, boiling at 229° C., separated from this oil.

This oil is readily soluble in all proportions of alcohol of 90 per cent., and differs in this respect from juniper oil, which is only soluble in four times its volume.

The oil of savin largely imported from the South of France, and distilled in the neighbourhood of Nimes, differs markedly from the above, the specific gravity, optical rotation, and percentages obtained on fractionation indicating the presence of turboptene to the extent of not less than 70 per cent., one part of the oil, moreover, requiring for solution six parts of alcohol of 90 per cent.

**Thyme Oil.**—Under the maimon of ol. origanii pharmacists are in the habit of employing, principally for veterinary purposes, the oils of *Thymus vulgaris* and other species imported from the Continent, principally from the South of France. Although it is possible to obtain oils from this district that are the product of *Thymus vulgaris*, the majority of the commercial oils are the products of that species more or less contaminated with *Thymus serpyllum*, as is shown by examination of their principal characters.

The two varieties of the oil known commercially are "red" and "white," the colour of the former being due to the reaction between the phenols present with iron, with which, during distillation, the oil comes in contact. I have received from Mona A. Merle (of Messrs. Bruno Court) of essential oils, Grasses that the intensity of the colour of the red oil is increased by the imperfect cooling of the condenser used in distillation. This is readily understood when it is explained that the herb is distilled on the mountain sides in rough stiles in convenient proximity to the growing herb, where it is often difficult to obtain water for the purpose of condensation. The red colour is entirely removed by redistillation, producing the white or yellowish oils already referred to.

The chief constituents of the oil are thymol and carvacrol, the boiling points of which are about 225° C. and 230° C. respectively. It is therefore by fractionation possible to ascertain approximately the proportion of these bodies present, although the actual percentage may be determined by treatment of the oil with caustic alkali.
The specific gravity of the samples examined varies considerably, being from 0.890-0.920 at 16°C., those having a specific gravity less than 0.905 of poor quality and yielding only small percentages boiling above 2200°. Typical commercial oils, both of the "white" and "red" varieties, are included in the appended table, one of the latter variety being greatly adulterated.

The pure oils are only slightly levorotatory, whilst the poor grades of oils show greater rotation, according to their admixture with the oil of Thymus serpyllum, which is more strongly levorotatory, the turpentine-adulterated oils reaching -20.

Pure oil should answer the following requirements.:
- Specific gravity. Not below 0.905 at 15°C.
- Rotation. Not more than -6.
- At least 25 per cent. should boil above 220°C.

**Winter-green Oil.**—It has been thought fitting to mention this oil, notwithstanding that it is not yet official in the British Pharmacopoeia, as it is being largely and increasingly used in this country.

The United States Pharmacopoeia, 1890, includes the following:

- Oleum betulae albæ (oil of sweet birch).
- Gautheris (oil of winter-green).

The oils of sweet birch and winter-green consist almost entirely of methyl-saliclylate, the first-named, on account of the far lower cost of the material from which it is distilled, constituting at the present time the natural oil of trade. Objection has been raised by Behringer to the introduction into the U.S. P. of synthetically prepared methyl-saliclylate, on the ground of its possible contamination with other esters. This may be avoided by the careful purification of the salicylic acid used in its production, and the absence of such impurities may be proved by checking the melting point of the salicylic acid liberated from the compound.

The specific gravity of the "natural" oils examined varied from 1.180 to 1.185. They were without exception optically inactive, confirming their production from Betula alba (the oil of gautheris being slightly levorotatory), and dissolved in an equal volume of 90 per cent. The whole of the oils distilled between 217° and 222°C. The specific gravity of a German sample of "artificial" oil examined was 1.085 at 15°C; it was found also to be optically inactive, dissolved in an equal volume of alcohol of 50 per cent., and to distil entirely between 218° and 222°C.

The salicylic acids obtained from these samples of both natural and synthetic oils, by saponification and liberation with hydrochloric acid, was found after one recrystallisation to melt at exactly the same point, 158°-75°C., indicating their identity and freedom in the case of the synthetic oil from para- and other cresotic methyl esters.

If, therefore, it is thought fitting to include in a new B.P. one of these oils, there seems no valid objection to the introduction of the "synthetic" oil, provided that compliance with the above-detailed characters be required.

---

**Provincial Transactions.**

**BRISTOL PHARMACEUTICAL ASSOCIATION.**

On May 10, a meeting of the Council of the above Association was held, Mr. Allen, President, in the chair. After the routine business, the Hon. Sec., Mr. Keen, reported the result of the class on the pharmacy of the organic portion of the Pharmacopoeia which he had held during the winter months.

The class consisted of thirteen students—apprentices, and assistants of pharmacists—who met weekly during twenty weeks. From the attendance book it was seen that the attendance was highly satisfactory, and it was clear the young men were well interested in the subject. The whole of the organic materia medica of the Pharmacopoeia was discussed and the specimens duly examined and explained.

A resolution moved by the President, and seconded by Mr. Schacht, was carried—thanking Mr. Keen for his able and patriotic services—and the hope was expressed that corresponding efforts might be made during the coming season so as to include the study of the inorganic preparations of the Pharmacopoeia, as well as those derived from organic sources.

---

**Reviews and Notices of Books.**

As usual this volume like its predecessors is full of important information concerning the transactions of the great City hospital during the year 1894. Among the many valuable papers it contains, the following are particularly worthy of attentive study:
- "Notes on Chloroform Anaesthesia," by Richard Gill;
- "The Dietetic Values of Food-stuffs Prepared by Plants," this is a lecture delivered before the Abernethian Society, by Rev. George Henslow;
- "Notes on Hydroxylamine Hydrochlorate as a Substitute for Nitrite of Amyl or Nitro-glycerin," by Dr. Lauder Brunton. There are three papers on diphtheria. Dr. Macan discusses the history of diphtheritic paralysis. Dr. J. A. Hayward deals with the diagnosis of diphtheria, and Dr. James Adams considers the question of the immunity of puerperal women from its infection.

Mr. Horder’s paper, "On the Life and Work of Percivall Pott," is sure to be earnestly read by
St. Bartholomew's men; it is a particularly interesting and able literary effort. There are several papers of purely surgical interest on important subjects, and the last third of the volume is occupied by the usual official reports of the Curator, and the Medical and Surgical Registrars. A mere glance at these tables shows what an enormous amount of medical and surgical work is accomplished within the walls of this great institution.

In this treatise on pharmacy, the author professes to supply to the student of pharmacy a compendious yet sufficiently detailed text-book for systematic study, and to those exercising the art, a trustworthy guide to be consulted in daily practice. In accordance with this plan, particular care has been bestowed upon the explanation of all operations and methods usually occurring in dispensing establishments and laboratories designed on a small scale. The work, therefore, appears to be intended particularly for the student of pharmacy and for the retail pharmacist. Bearing in mind the keenness of competition, it must appear exceedingly desirable that both should be intimately acquainted with improvements in every department of pharmacy—the former that he may be spared the loss of time in studying the theory and learning the practice of methods that are already antiquated; the latter that he may acquire an advantage over his competitors in producing by new methods preparations that by their superiority commend themselves to his clients, both medical and non-medical.

American pharmaceutical educational establishments and American pharmaceutical literature convey the impression that in the United States special attention is paid to the practice as distinguished from the theory of pharmacy. Certainly from America have proceeded most of the recent compendious works on pharmacy. The student of Coblenz's Handbook may reasonably expect therefore that from a practical point of view the work will be of especial value: in this he will not be disappointed. The matter is divided into four parts, theoretical pharmacy, galenical pharmacy, the art of dispensing and volumetric analysis, an arrangement which will commend itself to most pharmacists.

In Part I, the various weights and measures, the determination of specific gravity and the numerous operations practised in pharmacy, distillation, etc., are discussed. The compilation has been very completely made, and every pharmacist who takes an intelligent interest in his work will derive advantage and pleasure from the descriptions of the numerous balances, stills, percolators, and presses, most of which are accompanied by good illustrations. In the otherwise excellent chapter on specific gravity, the description of the operation of taking the specific gravity of a solid is followed by the statement that the "specific gravity is then found by the rule (1):

Divide the weight of the body in air by its loss of weight in water, the quotient will be the specific gravity." Surely a few words of explanation would be of great service in rendering the reasons of the steps taken intelligible to the student, and remove the impression that a rule to be learnt is being substituted for a principle to be understood, an impression confirmed by the frequent occurrence throughout the chapter of the words "then apply the rule."

In Part II., treating of galenical pharmacy, a general discussion of each class of preparations precedes the discussion of each particular member of the class. To such as are official in the U.S. Pharmacopoeia, methods of assay are as far as possible appended. The chapter on percolation, though short, is to the point, and includes the combined processes of percolation and expression, and of maceration and expression. Capsules and capsule-fillers are discussed at some length, as are also tablet and suppository machines, the most recent of the latter being described and figured; these machines appear to supersede the old-fashioned melting-method, although English pharmacists are by no means familiar with them. The 'Art of Dispensing' is dismissed in thirty-six pages, and calls for as little remark as the chapter on Volumetric Analysis. The paper and printing are excellent, and the work (which is not overloaded with too much ballast direct from the Pharmacopoeia) commends itself to both pharmacist and student as a volume of great utility.

Dr. Parkes' work is intended as an introduction to the study of hygiene, his main idea being "to give some simple yet practical information and instruction on the preservation of individual or personal health in the ordinary routine of domestic life." Accordingly, the first chapter is devoted to domestic water supplies, house cisterns, filters, and the purification of this prime essential of life. Next, under the heading of domestic refuse, the question of drainage is considered. Following this, ventilation, warming, lighting, and house construction in its sanitary aspect, receive attention. Chapter VIII., on Foods, is the longest in the book, as its importance deserves. The classification and composition of foods are briefly given, animal and vegetable diets are contrasted, digestibility, cooking, variety and admixture, etc., of foods receive attention, and then a mass of useful information on special points is condensed into some thirty pages. The concluding chapters treat of physical exercise, clothing, and the care of the skin, teeth, and bowels. The book is a thoroughly practical one, well written and free from fads, and seems to fulfil the author's ideal of embodying in a small compass "just that amount of practical knowledge of Hygiene which it is desirable that every individual should be in possession of."
Correspondence.

[Letters should be written as concisely as possible, on one side of the paper only, and preferably with name and address for publication.]

EXPERIMENTAL CLOUD FORMATION.

Sir,—Mr. Shaw's experiment, shown at the Royal Society's Soirée, can be easily repeated by anyone having at hand an ordinary glass retort of, say, one quart capacity, and filling this with water, then turning it on its back and allowing it to empty itself by gurgitation. It will be observed that when the pressure in the vacant part of the bulb is reduced, a mist is produced which lasts for a moment only, until the normal pressure is restored by admission of air. This phenomenon I have often observed, but I don't think it is generally known.

Yours,

THO. B. GROVES.

THE PRELIMINARY EXAMINATION.

Sir,—The publication of the report of the Council affords an appropriate opportunity to redress the vulnerable subject of the Preliminary examination. My apology for again referring to the matter is the impression on my mind that need for reform has not been sufficiently urged upon the Council, and I am sure that it is not generally realised how urgent that need is. After mature reflection, I believe it to be by far the most important and pressing matter before us, and one which would work a more beneficial revolution in English Pharmacy than any measure yet adopted.

When the educational history of these times comes to be written, the historian will be furnished by the Council of the Pharmaceutical Society with a beautiful instance of what may be called "Inverse educational architecture." Year by year it has raised its technical examinations, widening their scope and raising their character, yet the foundation of the structure, on the solidity of which the soundness of the whole fabric depends, has been left precisely as it has always been. What can be more absurd, for example, than to attempt to teach exact sciences like modern chemistry and physics to students who have never been taught geometry and algebra, and who are characterised by 50 per cent. of failures in very elementary arithmetic? My own experience (not a small one) of pharmaceutical students is that by far the most important cause of failure at the examination is not want of proper technical training, but lack of primary education; the men's minds have never been sufficiently developed to properly grasp the ideas presented to them. Many of them, indeed, are unable to understand the ordinary language of the text-books. And amongst the more intelligent it is deploring, to say the least of it, to see men engaged in research work wasting hours over laborious arithmetic to ascertain something which the application of a simple algebraical formula, intelligible to most modern school boys, would solve in a few minutes. It is futile to urge that amongst the senior students a few possess real educational attainments. They are abnormally specimens, and nine-tenths of them treat pharmacy merely as a stepping-stone to some other calling. But there is another side of the question which should appeal more directly to the bulk of pharmacists. Reform of the Preliminary examination would exclude a great many individuals who become the worst enemies of the calling they enter. It is not, as a rule, the educated man who lends himself to companies to evade the Poisons Act, nor is it the educated man who insists that grocers and chemists are to be placed in exactly the same category and acts accordingly. Apart from all this, does any reasonable man think that the Preliminary examination represents that amount of education which, in these days, may be reasonably expected in a first-class tradesman or mechanic and I suppose a pharmacist is the equal of these at least?

It has been stated that the inertia of the Council is due to opposition from parts of England where it is the custom to draw pupils or apprentices from the ranks of errand boys. I cannot think that the Council of the Pharmaceutical Society of Great Britain can attach real importance to opposition based on such a fact. That Council is not merely a representative of its constituents, it is also the guardian of the best interests of English pharmacy, and I do not believe that it will let the fancied interests of a few errand boys and others, who will not take the trouble to properly educate themselves, stand in the way of an important and necessary reform. The power to act has been for years in the hands of the Council, I feel sure that a majority advocate reform, and the reason for the delay seems to me inexplicable.

The reform I have always advocated is to adopt the same list of preliminary examinations as that accepted by the Medical Council for registration as a medical student. If this be thought too severe I would propose the incorporation of algebra (up to and including quadratics), Euclid (book 1), elementary mechanics, and a modern language, with the present examination. The foolish essay writing, which is indicative neither of reasoning power nor knowledge, might be excluded. Finally, I would call upon all those who are interested in the matter to urge upon the Council of the Society the immediate necessity of reforming an absurd and injurious anomaly.

198, Victoria Street, S.W.

A. CAMPBELL STARK.

THE COUNCIL ELECTION.

Sir,—I differ from your correspondent, Mr. Bradley, and would certainly not advise electors to vote for candidates to live nearest to the "Square," merely on the assumption that those who live farther away are remiss in their attendances. Two new members are bound to be placed on the Council at this election, and I hope the best two will be chosen; but, repeating my warning of last year, I do hope that voters will not allow each of the old councillors as have done yeomen service for us in the past to be left out in the cold in their anxiety to put new men in. Let us first stick to all that is worth keeping, and for the rest let us think twice before acting once amiss, and if I might presume to advise I would say vote rather for those who are in the trade, getting their daily bread by it, even though they may have occasionally to leave their business and make a journey of 200 miles or more to attend Council meetings.

Manchester.

HARRY KEMP.

Sir,—In your issue of May 11, I notice a correspondent advises members to vote for those gentlemen residing in your near to town. Why? Does it necessarily follow that those gentlemen are best suited to the work? Granting that very little interest is taken in the elections, would this tend to increase it? Again, your correspondent advises voters to erase the names of those who have attended fewest meetings. Can we do this when we are not aware of the circumstances which may have prevented attendance? Again I ask, does it necessarily follow that those who attend most meetings work hardest? Is it not possible that unscrupulous men might attend meetings simply for the chance of getting to London every month free of expense? I am glad names are suppressed, to publish them would at least, I think, be a mistake.

NEMO.
Notes and News.

Annual Dinner of British Pharmacists.—The members of the Pharmaceutical Society and their friends will assemble at the Whitehall Rooms, Hôtel Métropole, on the occasion of the Annual Dinner, on Tuesday next, May 21, at 6.45 p.m., and the President, Mr. Michael Carteigh, will take the chair at 7 precisely. Those who have not already obtained tickets (one guinea each), should apply at once to Mr. Richard Bremridge, 17, Bloomsbury Square, London, W.C.

Annual Meeting and Election of Council.—The fifty-fourth annual meeting of the Pharmaceutical Society will be held at 17, Bloomsbury Square, W.C., on Wednesday next, May 22, when the chair will be taken by the President, Mr. Michael Carteigh, at 12 o'clock noon precisely. The business will be to receive the Report of the Council and to elect the Council and Auditors for the ensuing year. Members and Associates in Business of the Society are reminded that their voting papers must be in the Secretary's hands on Monday at latest; otherwise the votes will not count unless the papers are handed in at the meeting by the voters personally.

Chemists' Assistants' Association.—The officers of this Association for the next twelve months are as follows:—President, Mr. E. W. Hill; Vice-President, Messrs. C. Morley and G. Roe; Treasurer, Mr. C. J. Strother; Literary Secretary, Mr. R. G. Guyer; Financial Secretary, Mr. R. Melsbourn.

Failures at Pharmaceutical Examinations.—The New England Druggist confirms the accuracy of the statistics recently quoted (ante, p. 881) from a Boston newspaper, with regard to the proportion of failures (88.4 per cent.) in the examination for registration as pharmacists in Massachusetts.

American Pharmaceutical Association.—The next meeting of this Association is to be held at Denver, Colorado, commencing August 14. Papers on commercial and allied subjects, and other communications, should be addressed to Mr. George J. Seabury, Chairman of the Commercial Section, 59-61, Minden Lane, New York, U.S.A.

Re-Registration of Pharmacists in New York.—The Legislature of New York State has referred two Bills providing for the annual re-registration of pharmacists to committees, but they are not expected to prosper.

Pharmaceutical Ethics in Austria.—As illustrating the strictness with which the dealings of the Austrian pharmacist are supervised by the authorities, the Vienna correspondent of the Medical Press narrates that, in a large provincial town, a local chemist has been punished by the Minister of the Interior for compounding the prescription of an innocent nature which was written and sent to him by a popular charlatan.

The Early Closing Bill.—The chemists and druggists of Dundee and Leochie have unanimously petitioned Parliament in favour of Sir John Lubbock's Early Closing Bill, believing that it will confer a great boon on a large section of the community.

Ceylon Botanic Gardens.—Dr. Trimen, F.R.S., in his report for 1894, states that the export of tea has remained stationary for the year (84,591,714 lb., as against 84,406,064 lb. in 1893); coffee continues to be neglected (32,205 cwt. exported); whilst of cacao, which fluctuates continually, 21,110 cwt. was sent away in 1894. The cultivation of trees yielding Sarsa indiarubber is again referred to, one tree experimented on having yielded as much as 3 lb. 3 oz. of dry rubber during last year. Amongst other economic plants briefly alluded to are those yielding gutta-percha, gambir, camphor, and cubebes.

'Science Progress.'—In the May number of this periodical, Professor Oliver J. Lodge rehearses a summary of most of the more prominent and interesting facts bearing on the connection between light and electrification. He proposes to collate these facts, and consider their bearing in a future article. Dr. A. D. Waller deals with two fundamental 'laws' of nerve-action in relation to the modern nerve-cell—the law of tropic action and the law of forward direction; Dr. G. A. Buckmaster prefaces an instructive article on the antitoxins of diphtheria by commenting on the nature and value of the connection between the biological sciences and applied medicine; and other articles are on 'Methods of Petrographical Research,' by Alfred Hacker; 'Progress in Physical Chemistry during 1894,' by J. W. Podger; 'Notes on the Reproductive Organs of Olive-brown Seaweeds,' by George Murray; and 'Budding in Tunicata,' by W. Garstang.

Pharmacy in Victoria.—The report of the Pharmacy Board of Victoria for 1894 shows that 126 candidates presented themselves for the Preliminary Examination during the year; forty for Chemistry and Practical Chemistry; thirty-eight for Materia Medica and Botany; thirty for the Final Qualifying Examination, and one for the Modified. They included students from New South Wales, New Zealand, Queensland, and Tasmania. Sixty candidates passed the Preliminary, twenty-two the Final, and one the Modified Examination. The number of Pharmaceutical Chemists registered under the Pharmacy Act, 1876, was thirty-four, bringing up the total number to 814, whilst forty-nine apprentices were registered, and 126 certificates granted to dealers in poisons distant four miles from a registered pharmaceutical chemist.

Plymouth, Devonport, Stonehouse and District Chemists' Association.—An elementary examination in practical chemistry will be held at the Technical Schools, Plymouth, on Tuesday, the 28th inst., at 7 p.m. Unqualified members of the Junior Section only are eligible. All those wishing to compete must communicate with the hon. sec., Mr. James Cocks, Edgecumbe Street, Stonehouse, by the 23rd inst.
Parliamentary News.

IMPORTED MILK.

In the House of Commons on Thursday, May 9, Mr. Lambert asked the President of the Local Government Board if he had any evidence to show whether milk obtained from cows suffering from foot-and-mouth disease was injurious to health, or whether milk which had been imported from Holland, which was scheduled under The Contagious Diseases (Animals) Act, 1878, as containing cattle infected with foot-and-mouth disease; if so, would he take proper precautions to prevent such milk from being utilised for human consumption in this country.

Mr. Shaw Lefevre replied that there was no evidence that disease had been spread in this country by imported milk. With insignificant exceptions imported milk was in a condensed form, and the processes of heat to which it was subjected, he was advised, destroyed its powers to convey infection, whether of foot-and-mouth disease or tuberculosis. The Local Government Board had no power to prohibit the importation of foreign milk.

UNIVERSITY OF LONDON.

In the House of Lords on Thursday, May 9, Lord Playfair, in introducing a Bill for the reconstitution of the University of London, said that a Royal Commission was appointed two years ago by the late Government for the purpose of considering whether London University should be merged in a teaching university, or whether a new university should be formed for London. The Royal Commission, convened in the decision of a former Royal Commission on the same subject, thought that the London University, from its reputation and convenience of examination, should be retained rather than that a new university should be established. Accordingly they issued a scheme which was very favourably received by all the interests concerned and adopted by the Senate and Convocation of London University, and resolutions in its favour were passed by all the colleges and bodies interested. The Royal Commission pointed out that it would be exceedingly difficult to carry out the scheme by charter, and recommended it should be carried out by Act of Parliament—by statutory commission. The object of the Bill was to carry out the views of the Royal Commission. Of course, an elaborate scheme such as that would be explained on the second reading, when the Government would be prepared to name the statutory commissioners. There was no intention in the Bill to interfere with the Imperial character of the university, which at present examined students external to London, and this particular characteristic of the university was specially preserved. The Bill was a very simple and fully contained Bill, and it would be better for him to reserve an explanation until a further day. He now moved the first reading. The measure was read a first time.

Miscellaneous News.

POISONING OF CATTLE BY NITRATE OF SODA.—At the time of year when nitrate of soda is being used as top dressing, a word of warning as to its effects upon live stock may not be out of place. Two years ago a number of cattle died rather suddenly on a farm in South Lincolnshire, and an inquiry into the circumstances of the case left no room for doubt that death arose from the eating of nitrate of soda which the animals obtained from bags which had been used in conveying this fertiliser into the field, and had afterwards been left lying about. More recently a case has occurred on a farm in Massachusetts, in which eleven cows out of a herd of fifteen died as a result of having had given to them nitrate of soda, in mistake for common salt (sodium chloride). The fifteen cows had been out a grass all day, and were driven to the stales in the evening, when an attendant gave to all except two what he supposed to be common salt, thoroughly mixed with a small quantity of wheat bran. Apparently, all the animals ate heartily. Two hours later the cows attracted notice by the noise they were making, and when examined they were found to be uneasy and evidently in pain, and several died within an hour or two. The only skilled advice obtainable was that of a medical practitioner, who, thinking the case was one of arsenic poisoning, prescribed accordingly, but before morning eleven of the cows were dead. An examination of samples of material collected from the mangers, from a pail containing a mixture of bran and salt that had been taken from the mangers, and from various other places revealed the presence of large quantities of nitrate of soda, but no common salt. An analysis of the contents of the stomach failed to reveal any trace of arsenic, lead, or other mineral poison.

Nearly twenty years ago somewhat similar cases were recorded in the Archits Vegetaires. A horse had drunk freely of a solution of nitrate of soda, and exhibited many of the symptoms that were consequently noticed in the Massachusetts cattle; the administration of strong infusions of coffee and alcohol and irritant catarrh relieved the animal, which, in a few days completely recovered. In another case four bags of nitrate of soda had been placed at a distance on a grass field and allowed to remain some five hours before being applied. Meanwhile, some of the nitrate had become washed from the bags upon the ground by a fall of rain. Three days later the cows were turned into the pasture and obtained the salt by licking it from the herbage in the vicinity of which the bags had stood. They showed symptoms of poisoning, but ultimately recovered. One other cause worth noticing is that in which two hundred bags which had contained nitrate of soda were washed in large tubs of water close to which the cattle passed on their way to the pasture. A few hours afterwards many of the cows were seen to lie ill, and within eight hours two of them had died. The bags turned out to be the first two that had left the stales, and consequently had time to drink more of the solution than the others. These cases all serve to show that care should be exercised upon stock farms in the handling of nitrate of soda, and there is no better period of the year than the present for enforcing the lesson. — Times.
MISCELLANEOUS NEWS.

BRISTOL NATURALISTS' SOCIETY.—At a meeting of this Society, held on Thursday, May 2, at University College, Bristol, Dr. Young gave the presidential address on the "Liquefaction of Gases." Very little, he said, was known by chemists about gases till the investigations of Priestley, but even in his time gum and honey were obtained from them, but he made no attempt to liquefy them. In 1806 the first success was obtained with chlorine. The great pioneer, however, in this direction was Faraday, who not only succeeded in liquefying many gases (among them ammonia, hydrochloric acid, sulphur dioxide, and carbonic acid), but even when he did not succeed pointed out the lines on which success was to be finally achieved. The gas must be subjected either to compression, cooling, or a combination of these two agencies. Dr. Young showed Faraday's method of obtaining liquid ammonia by warming some chloride of silver, to which ammonia had been attached, in one end of a sealed tube, dipping the other end into a freezing mixture, where the ammonia given off is condensed into a liquid. Another very pretty experiment was the condensation of the red fumes of nitrogen trisulphide into a dark blue liquid. Oxygen, nitrogen, hydrogen, carbon monoxide, and hydrochloric acid gas readily liquefied after a long time, and were called "permanent gases." Dr. Andrews was the first to show, by some remarkable and exact experiments with carbonic acid, that above a certain temperature, which he called "critical temperature," no amount of compression produces liquefaction. In the case of carbonic acid this temperature is 31°, but in that of some of the so-called permanent gases the critical temperature is so low (in the case of hydrogen, for instance —233°) that experimenters have failed from having applied compression at too high temperatures, thus foreshadowing their results. Some twenty years ago two foreign observers—Pilet and Calletet—succeeded in liquefying oxygen and nitrogen (whose critical temperatures are —119° and —166° respectively), but it was only early this year that Messrs. Wrobleski and Olaszewski succeeded in reducing hydrogen to a liquid state. The principle of the method employed is the case of these refractories the gas is to pass the gas under pressure into a tube which is immersed in a liquid whose boiling point is naturally very low, and is still further and artificially lowered by being subjected to a much reduced pressure. The ethylene under reduced pressure can be made to boil, and when the gas liquefied it can be used to boil at a much lower temperature still, and in this way probably hydrogen has been liquefied. The lecture was freely illustrated by experiments and diagrams.

UNIVERSITY OF LONDON.—The Daily Telegraph remarks that for all practical purposes Convocation of the University of London has decided to separate itself from the scheme to found a real university in the metropolis. Mr. Bompas, Q.C. moved to rescind the resolution passed in January, "That there shall be a separate scheme for a new University of London," and two and a half to declare "that if a local teaching body for London be able it ought to be constituted apart from the existing University of London." This was seconded by Dr. Hart, and supported by several speakers, including some outside representatives; while, on the other side, Dr. Pitch, Mr. Cozens-Hardy, Principal of the great teaching institution, "to promote scholarship and research," and to make the greatest capital in the world, as Dr. Pitch observed, also "a great seat of learning." On a division, the motion was rejected by 226 votes to 117. This was the decision of London on the subject. It represented the desire of all the colleges, medical schools, and the whole teaching profession of the metropolis, and it affirmed the principle of what is known as the Gresham scheme, now before Parliament, which is the outcome of much discussion and inquiry by two Royal Commissions. But another vote had to be taken to elect to the Senate a Fellow in place of the late Sir William Savory. Not ostensibly, but really, this election was a test of the opinion of Convocation on the Gresham scheme. Dr. Bateman Napier was the nominee of the committee opposed to it, and Mr. Cozens-Hardy represented those in favour. In this contest the country members sent up their voting papers, and the final result was—Dr. Napier, 1231; Mr. Cozens-Hardy, 733. In other words, London will certainly have a teaching university, and that is long; but, in order to preserve the privileges of non-collegiate provincial students, the country members of the existing University of London decide by a majority of nearly 500 that it shall remain as it is, merely an examining board.

THE BEE PRODUCTS OF EUROPE.—The yearly production of beeswax and honey attains very considerable dimensions in the countries of Continental Europe. According to the latest reliable data, the annual output of wax is about 15,000 tons, with a value approaching £1,350,000. Of honey the annual production is estimated at 80,000 tons, and its value at £2,000,000. The following are the figures for the most important countries, the small balance of 5000 tons belonging to other countries which are not named below:

In the United States of America there are about 2,500,000 stocks of bees, producing annually some 30,000 tons of honey. No statistics relating to this industry are collected in Great Britain, but it is otherwise in Ireland. —Times.

THE SANITARY CONFERENCE.—A three days' conference on "Sanitary Progress and Reform" commenced in Manchester on April 24 in connection with the annual meeting of the Manchester and Salford Sanitary Association. A meeting introductory to the conference was held in the Museum of Owens College, at which Professor Boyd Dawkins delivered an interesting address on "The Pre-Historic Traces of Sanitation." In the Paleolithic Age dry areas were chosen for habitation, and Neolithic man chose spots with natural drainage. Towards the close of the Bronze Age the most elaborate system of refuse heaps was found, but there was no evidence of any artificial water supply. In the period of the Iron Age, however, were recorded early interments of children, and in that particular they could look back as far as those times for the example of a reform which was necessary in some part of this country. In the
Bronze Age evidence that cremation was the rule was to be found in the limestone ranges of Derbyshire and on the chalk downs of Wilt. The excavations at Silchester showed an elaborate and perfect system of arterial drainage. It was resolved at the Sanitary Association meeting that a smoke abatement league should be formed for the purpose of suppressing the smoke nuisance, the nucleus of the league to consist of organisations at present existing in Manchester, Rochdale, Middleton, Oldham, and Bolton, and that the Committee of the Manchester and Salford Non-Smokers Association should be requested to take immediate steps for the formation of a Committee of Management of the League. The Bishop of Manchester said the Association would do a very useful work if it would print and circulate in large numbers a cheap edition of such papers as that which Lady Priestly had recently written upon "The Penalties of Ignorance."—Sir H. Roscoe, M.P., afterwards took the chair at the Conference Session, and in introducing the question of Smoke Abatement, said he agreed with a remark of the Lord Mayor, that whilst they paid attention almost entirely to the smoke from factory chimneys and from manufacturing operations, they paid little attention with the larger question, namely, that of the smoke from ordinary household fires.—Mr. A. E. Fletcher, Chief Inspector of Alkali Works, delivered an address, in which he urged that the compulsory powers as to vapours from chemical factories should be given in relation to coal smoke. Until that had been remedied, the Act would hardly be cracked.—Dr. Cohen, of Yorkshire College, spoke of the work which had been done in Leeds in the way of interesting manufacturers and working people, and of taking observations of the extent of the nuisance.

DR. LUDWIG MOND ON THE STUDY OF CHEMISTRY.—In his speech at the opening of the Schorlemmer Laboratory, Dr. Ludwig Mond said he agreed that it was desirable to cultivate physical chemistry and inorganic chemistry much more than had been done, and he was very glad that the great supremacy which organic chemistry had enjoyed—more particularly in Germany, the home of chemistry—was now being contested by other and equally important branches of our science. But great, and very grave, was the danger that inorganic chemistry had greater and more important problems still to solve; and in this country, which had given birth to so many of the most important steps in advance of that science, it had not received that amount of general attention which it had deserved in the past, and which it still deserved in the future. Schorlemmer had shown that, if to-day we could not make morphone, quinine, and similar bodies artificially, the time was near at hand. If we could not make quinine, we had already found a partial substitute in antipyrin, and its introduction into therapeutics had lowered the price of quinine considerably. Another important problem was the synthesis of the ingredients of our daily food, such as sugar, gum, and starch. Those bodies were nearly related to each other, for we could convert the two latter into different kinds of sugar, and sugar into starch. Then the synthesis of sugar was imminent had already been stated. But all attempts hitherto made for the purpose of producing living matter artificially had failed, and the enigma of life could only be solved by the synthesis of an albuminous compound. Professor Fischer, in a lecture delivered some time ago in Berlin, expressed himself full of confidence that the time would arrive when we might attack successfully even the problem of the constitution and synthesis of the albuminoide, and might thus approach the problem of the origin of life. Surely with such a prospect as the ultimate result of the pursuit of organic chemistry no amount of work, no amount of thought, no amount of time and trouble devoted to that study would be too much if it is well employed in leading successfully to the great end in view, although the goal might not be reached for generations to come.

EDINBURGH DISTRICT CHEMISTS' TRADE ASSOCIATION.—The third annual meeting of the Association was held in the Pharmaceutical Society's House, 36, York Place, on Tuesday, the 14th inst., at 9 p.m., Mr. Peter Boa, President, in the chair. The minutes of last meeting were read and approved. The Honorary Secretary (Mr. C. F. Henry) read the annual report and financial statement, from which it appeared that the Association had had a very successful session, and the year closed with an increased membership. During the year the Association had considered the practical difficulty arising from the prescribing of proprietary or stamped medicines, and 600 circulars had been issued to medical practitioners in the Edinburgh district, drawing their attention to the difficulties arising in this way and suggesting a means whereby they might be obviated. The Association had also secured from the Inland Revenue authorities a formal sanction of the extension of the concession as to labelling of Bland's pills to other similar preparations. The financial statement showed a balance in favour of the Association of £12 10s. 10$. Mr. D. Wyllie moved adoption of the financial statement, Mr. R. J. Macdougall seconded, and unanimously adopted. On the motion of D. MacKenzie, seconded by W. Burley, the report was adopted. Membership 62.

The Committee recommended that the Association plan to visit this year at Kincross, going by train to Perth and driving to Kincross by way of Bridge of Earn and Glen Farg. This was unanimously agreed to, and the picnic was fixed to take place on June 12. Tickets, 12s. 6d. single, 23s. double.

The following office bearers were elected for next year:—Peter Boa, President; John Bowman, Vice-President; Claude F. Henry, Secretary and Treasurer; and Messrs. Aitken, Forrest, Glass, R. L. Hendry, McGlashan, Wyllie, Leask, Smith, MacLaren, Maclean, McDougall, and Lunan, as members of Committee.

On the motion of Mr. D. MacLaren, a hearty vote of thanks was awarded to the Chairman, and the meeting closed.

THE EXHIBITORS' ASSOCIATION.—At a meeting of intending exhibitors at the forthcoming British Medical Association Museum, held at the Queen's Head, Strand, on Thursday, May 2—

Mr. F. J. Robman briefly stated that since the Museum Committee had sent out their circular bearing on the next museum, he had, as the chairman of the last exhibitors' meeting (held in November, 1891), received a great many intimations from various firms that large reasons regretted it advisable to call together another meeting for the purpose of discussing certain points of interest to the exhibitors. He had complied with these requests, and now took occasion to thank those present for having so promptly and universally responded to the call.

Mr. Robman was then unanimously elected in the chair, Mr. E. W. Lane (Armour and Co.), acting as permanent secretary.

The Chairman drew attention to the great success achieved by last year's Committee in securing for the museum the first floor of the Examination Hall of the Royal College of Physicians and Surgeons, situated on the
Poisoning Cases and Inquests.

Chlorodyne.—Edward Rowles, a retired farmer, died on Monday, April 29, at Mistley, from the effects of chlorodyne, self-administered. Verdict: "Suicide during temporary insanity."

Poisonous Lotion.—A young man, named Rose Richards, an accountant, died at Pontycymmer, on Wednesday, May 8, through drinking a small portion of a lotion supplied to him for the purpose of treating a bee-sting.

Oxalic Acid.—A woman named Hardwick died on Wednesday, May 8, at 341, Caerleon Road, Newport, from the effects of oxalic acid, contained in some baking powder.

 Laudanum.—John Henry Hartley, aged 39, died on Sunday, May 5, at 42, Fitzwilliam Street, Sheffield, from the effects of laudanum, self-administered. Verdict: "Death from an overdose of laudanum administered by himself, probably to induce sleep."

Prussic Acid.—John Shipp, aged 41, died on Saturday, April 27, at High Street, Billericay, from the effects of prussic acid, self-administered. Verdict: "Suicide while of unsound mind."

Laudanum.—Matthew Wood, a middle-aged man, died on Friday, May 10, at Bolton, from the effects of laudanum, self-administered.

Strychnine.—At the inquest held on the body of James Hale (see ante, p. 1022), evidence was given to show that death was due to strychnine contained in a packet of Battle's vermin-killer, and the jury returned a verdict to the effect that deceased took his life while in a state of temporary insanity.

Prussic Acid.—Edward G. Knott, aged 55, died on Friday, May 3, at Margate, from the effects of prussic acid, self-administered. Verdict: "Suicide whilst temporarily insane."

Spirit of Salt.—An inquest was held on Thursday, May 9, at Bishop Stortford, on the body of Thomas Searles, who died from the effects of spirit of salt, having been taken in mistake for whiskey. Verdict: "Accidental Death."

Corrosive Sublimate.—George Denning, a small farmer and dealer, died on Saturday, May 11, at Forton, near Chard, from the effects of corrosive sublimate, self-administered.

Obituary.

Arnold.—On May 6, Alfred Arnold, Chemist and Druggist, Cwm Avon. (Aged 79.)

Appleby.—On May 12, Calvert Appleby, Pharmaceutical Chemist, of East Retford. (Aged 47.)

Wheeler.—On May 2, John Wheeler, Pharmaceutical Chemist, Chipping Sodbury. (Aged 72.) Mr. Wheeler had been a member of the Pharmaceutical Society since 1847.

May 13, 1893.]

POISONING CASES.

The New Disease "Prittacose" from Newly Imported Parrots.—Professor Nocard (Revue Intern. de Med.) has isolated a specific organism from the marrow of the humerus of a parrot, which is probably the infective cause of the well-marked feline disease terminating in pneumonia, which has been traced to infection from newly-imported parrots; numerous cases of which have occurred in Paris since 1892. It is suggested that the sale of parrots by itinerant vendors should be restricted.

Myrcene is a new hydrocarbon, obtained by Power and Kieber during the fractionation of oil of bay. It is a limpid liquid, having the formula C_10H_16, s. G. 0.7023 at 15°C., and index of refraction [n] = 1.4673.
Notes and Queries.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally.]

OPTICAL ROTATION OF AN OIL.

[856.] By "the optical rotation of an oil" is meant the power of the oil to rotate the plane of polarisation of a ray of light passed through it; rotation in the direction in which the hands of a watch move, or in the opposite direction, indicated by right-rotatory (+) or left-rotatory (−) respectively. The instrument employed for determining the extent of the rotation is called a polarimeter, and substances capable of rotating the plane of rotation of a ray of polarised light passed through them are described as optically active. Since the angle of rotation depends upon the temperature, the nature of the substance examined, the thickness of the layer through which the polarised ray passes, and the wave-length of the light used, which should be mono-chromatic, it is usual to speak of the "specific rotatory power" of a substance. This is found by means of the following formula:

\[ [\alpha] = \frac{\alpha}{l} \times d \]

in which \([\alpha]\) = specific rotatory power; \(\alpha\) = angle of rotation of the plane of polarisation of light of stated wave-length; \(l\) = length of column of liquid in decimetres; and \(d\) = specific gravity of liquid referred to water. Observations are made at a common temperature, and the wave-length of the light employed is expressed by a letter below the bracket, thus \([\alpha]_d\) means specific rotatory power for light of wave-length D.

TRAUMATISM.

[857.] A correspondent remarks that this preparation appears almost identical with liquid gutta-percha B.P., except that purification is employed to remove a part of the solvent. A better way, he considers, is to employ gutta-percha tissue, and to add 1 part by weight — torn into small pieces — to 12 parts by measure of chloroform, contained in a glass-stoppered bottle with frequent agitation. A solution of this consistency is thus quickly obtained.

ORIGIN OF CHEMICAL TERMINATIONS.

[888.] The terminations in the words "sulphate" and "sulphite" are of French origin. In 1787 the method of chemical nomenclature proposed by M. de Fourcy was published; this still forms the basis of the present system. Lavoisier's ideas were most prominent in the scheme which was practically an embodiment of his antiphlogistic doctrines. The compounds of oxydine were divided into oxides and acids, and the names of the latter were distinguished by the terminations -eux or -eux, or -aque (Aug. -te), respectively, according as the acids contained more or less oxygen. The important rule was also introduced, and is still maintained with its original force, that the names of salts formed from acids distinguished by names ending in -eux (-eux) should terminate in -ite, and those from acids in -aque (-te) should terminate in -ate.

SYRUP OF FERROUS IODIDE.

[859.] A solution from which this syrup can readily be prepared, has been devised by M. Tripels, of Brussels as follows:—Resublimed iodine, 45 Gm., and iron filings, 20 Gm., with distilled water, g:z-, are allowed to react to form ferrous iodide. The solution is then filtered and aged.其余等7 Gm. with water, after which glycerin, 15 Gm., simple syrup, 15 Gm., and solution of citric acid (10 p.c.), 3 Gm., are added, the whole making 50 Gm. This solution is kept in colourless bottles exposed to the light and when it is required to prepare the syrup, 5 Gm. of it is mixed with syrup of orange flowers, 20 Gm., and simple syrup, 75 Gm. (Ann. de Pharm.).

NOTICES, LETTERS, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENl WEEK'S JOURNAL SHOULD BE ADDRESSED TO THE EDITOR, NOT LATER THAN THE FIRST POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED BY THURSDAY MORNING. ADDRESS: "PHARMACEUTICAL JOURNAL, LONDON."

ADVERTISEMENTS (except for the 'Exchange' column) orders for insertion, and communications respecting transmission of same, should not be addressed to the Editor, or delay will be caused. See directions on Editorial page.

Correspondents who wish notice to be taken of their communications must write in ink on one side of the paper only, and should authenticate the matter sent with their names—of course not necessarily for publication. No notice can be taken of anonymous communications.

Drawings for illustrations should be done with pen and ink (Chinese) and consist of clear, sharp lines, without shading. They should also be sent twice the desired size, so as to allow for reduction.

Names and formulas should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

* * * Queries will be replied to as early as possible after receipt, answers of sufficient general interest being given under the heading Notes and Queries.

LETTER.

BOTANICAL CURiosITIES.—Mr. F. P. Balkwill, of Evesham, sends some specimens of Viola odorata, with cleistogamous flowers, found in a copse shaded by trees on a spur of the Cotswold Hills. They do not seem to have developed normal flowers with the blue petals. He has also found a primrose with stamens and pistils of the same height, half the length of the corolla tube.

ANSWERS.

T. H. Muir.—We have no report of the matter you mention.

P. Dawson.—See "Notes and Queries" column.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Aird, Barker, Basley, Bennett, Butler, Bywater, Clarke, Cocke, Cripps, Dawson, Dobie, Fitzgerald, Franks, Guyer, Gill, Green, Harrison, Hill, Hogg, Holloway, Hooper, Howorth, Kemp, Kirkby, Macartney, Marshall, Morley, Muir, Naylor, Payne, Perry, Rideal, Robinson, Schacht, Spottiswood, Stark, Sutton, Thompson, Williams, Wright.

Publications Received.

[Publishers are requested to state the price of books sent for review.]

REPORT OF THE ROYAL BOTANIC GARDENS, CROYDON, By the Director, Mr. H. TRIMEN, M.K., F.R.S. From the Director.
THE ANNUAL DINNER OF THE SOCIETY.

The annual dinner of the members and friends of the Pharmaceutical Society was held on Tuesday, May 21, at the Whitehall Rooms, London, Mr. Michael Carteigne (President) in the chair. Amongst the guests were Sir F. Abel, Bart., F.R.S. (Director and Secretary, Imperial Institute), Dr. A. G. Bateman, the R. Hon. J. Bryce, M.P. (President, Board of Trade), Dr. F. H. Champneys (President, Obstetrical Society), H. J. Chanevy, Esq. (Standards Department), Sir Dyce Duckworth (Treasurer, Royal College of Physicians), J. Laidlaw Ewing, Esq. (Chairman of Executive, North British Branch), Dr. R. Farquharson, M.P., Professor Michael Foster, F.R.S. (Secretary, Royal Society), Sir Walter Foster, M.P. (Parliamentary Secretary, Local Government Board), A. Vernon Harcourt, Esq., F.R.S. (President, Chemical Society), Christopher Heath, Esq. (President, Royal College of Surgeons), A. Braxton Hicks, Esq. (Coroner for S.W. London), C. R. Hodgson, Esq. (Secretary, College of Preceptors), Professor Victor Horley, F.R.S., Dr. Padman, W. P. Paterson, Esq., F.R.C.S., Major C. Probyn, L.C.C., Sir Richard Quain, F.R.S. (President, General Medical Council), Dr. W. J. Russell (President, Institute of Chemistry), Professor J. Burdon Sanderson, F.R.S., (Regius Professor of Medicine, Oxford), Dr. T. Stevenson (President, Society Public Analyst), G. Thatcher, Esq. (Royal College Veterinary Surgeons), Dr. Thorne Thorne, C.B. (Principal Medical Adviser Local Government Board), Professor Thorpe, F.R.S. (President, Society Chemical Industry), Professor W. A. Tilden, F.R.S., C. S. Tames, Esq., F.R.S., E. Trimmer, Esq. (Secretary, Royal College of Surgeons), Dr. Dawson Williams (British Medical Journal), Sir H. Trueman Wood (Secretary, Society of Arts).

The health of the Queen having been duly honoured, The President proposed "The Houses of Parliament." He said there were many Houses of Parliament in different countries, but he did not know of any form of Parliamentary Government which was so well adapted to a thoroughly constitutional and free people as that which prevailed in this country, or which had formed the model on which so many others had been framed. After referring to the difficulties in connection with imposing an income tax in the United States, he said he did not believe the statement which was sometimes made that Great Britain was no longer the leader of Parliamentary Government. Both in the House of Commons and the House of Lords there were men with as great ability as any who ever occupied a place there, and in the former men of mark alone had any chance of attaining a position. He concluded by a tribute to the merits of Mr. Bryce, President of the Board of Trade, whose name he begged to couple with the toast.

The Right Hon. James Bryce, M.P., in respond-
large on the intimate relations between pharmacy and medicine, and he would simply couple with the toast the names of Sir Richard Quain, President of the Medical Council, as representing in his official capacity the whole of the medical profession, and Mr. Christopher Heath, President of the Royal College of Surgeons.

Sir Richard Quain said the Medical Council was originally constituted for the benefit of the medical profession and the public, and though it had been constituted of rather incongruous elements, he could not doubt, seeing the names of those who were associated with it, that it would have, sooner or later, most important results. It included representatives of all the medical authorities in the kingdom, each of which had its own special vocation and authority, and was jealous of all the others; but that period of jealousy had passed away, and he was happy to think that the Council was now doing exceedingly useful work. It had succeeded in extending the period of medical education from two and a half or three years to five years, which would ensure better educated men entering the profession, and it possessed a power greater than that of any court of law, for it could declare the conduct of any member infamous, and remove him from the roll, and from its decision there was no appeal. He trusted therefore in time every one who brought disgrace on the profession or injury to the public would be weeded out. The pharmacist supplied the materials with which the physician and surgeon had to combat disease, and he hoped this supply would be continued, and that they would not have medicines forced upon them from Germany or elsewhere. He protested against the idea of a medical man going about carrying his pharmacy in his waistcoat pocket. Ready-made physic, like ready-made clothes, was never a good fit, and he was not particularly in favour of new remedies with names so long that nobody could spell them. The Council was now engaged on a new Pharmacopoeia, in which it had the assistance of many eminent pharmacists, and he hoped the result would be satisfactory, and that the medical profession and the chemists would long be associated in friendly intercourse.

Mr. Christopher Heath (President of the Royal College of Surgeons), said he had the honour of representing a Corporation infinitely older than the body represented by Sir R. Quain. That body was only brought into existence in 1858 by Act of Parliament, but the Surgeons' came into existence in the time of Homer. Afterwards there was a corporation of barbers and surgeons, and later on the surgeons separated from the barbers for obvious reasons. Since then they had been a corporation by themselves, and they had to thank the Pharmaceutical Society for the work it undertook on their behalf. Professor Attfield informed him that they had 7000 answers to circulars with regard to the new Pharmacopoeia, but not one from any member of the Council of the College of Surgeons. He could only say he was not surprised at it. Surgeons were very glad to use drugs when necessary, but they used very few, and he did not think as a rule they employed those with the long names to which Sir R. Quain had referred. As he told Professor Attfield, he hoped they would not make any change in the strength of laudanum, and that the old and well-tried remedies would not be discarded.

The President next proposed the toast of "Science," and in connection with it he wished especially to refer to the teaching of science. When he was young it was very hard for science to get a hearing, but things had changed since then, and there was now a great outcry about technical education, which, as he understood it, meant that those who had to do with any particular branch of art or manufacture should know the conditions precedent upon which their practice depended. Elementary science was the condition precedent to all technical education. Many years ago, when text books of science were few and far between, the Hon. Robert Boyle was once asked what should be done with a sum of £10,000 lying to his credit at the bank, and it was suggested that it should be re-invested. His reply was—Do not trouble me with these matters of detail. Perhaps men of science nowadays were not so indifferent to matters of business, and at any rate there was great competition amongst them for distinction and priority of discovery. A great deal had been done for the teaching of science by the University Colleges, and now the County Council were also joining in the work by establishing technical schools. He coupled with the toast the names of Professor Michael Foster and Mr. Vernon Harcourt (President of the Chemical Society).

Professor Michael Foster said he was taken quite by surprise, and he could not make a speech, but he would tell them a tale. The other day, feeling indisposed in Bond Street, he entered a chemist's shop at hand, and asked the urbain gentleman behind the counter for a soothing draught, which was furnished to him, and his indisposition disappeared; whether the compound given to him contained some phenyl in it or not he did not know, but there seemed to be a change in his mind. There was an old saying that it was good to see ourselves as others see us, and under the influence of that draught he obtained an outside view of men of science. He remembered a friend telling him once men of science are the most cock-sure people he ever met, and under the influence of that draught he saw it. He saw that men of science were Pharisees of the worst description, who always had written on their phylacteries, "We are the salt of the earth, we are always sitting upon a hill with the kingdoms of the world spread before us." He could assure them he was dreadfully affected at that view; he said to himself, there are a set of men who, if ever power fell into their hands, would prove a tyranny in comparison with which that of the Church of Rome in the palm days of the Inquisition would be mild, and he said to himself the whole remainder of your life must obviously be devoted to counteracting this terrible and dangerous power. But then the effect of
the draught began to pass off, and he saw there was something to be said for men of science, amongst other things that the very spirit which gave them such power that if their brother’s neck were placed beneath their heel so that they could crush it at once, at the same time took away the desire to injure; for the very spirit which gave them that power immediately set them on wings to obtain other results, starting from those which they had already obtained so that they never stooped to make a practical use of the powers which they had gained. He saw also that they were happily divided amongst themselves, that the very spirit of a scientific man was to believe that his brother was a liar, and that his one duty was to prove it, and he said to himself that tyranny so divided amongst itself could do no harm to mankind. Then he turned from the men of science to the work of science itself, and was not this a work which had turned the world upside down? Was it not, as Mr. Bryce had said, a work which was felt everywhere, a great flowing tide, covering the plains and surging up into every nook and corner, and was there any place where this influence was more felt than in the Pharmaceutical Society! The work which science was doing was a work of many kinds, and like everything in this world, the good brought more or less evil with it. There was a time when the life of a chemist and druggist was a simple matter, when a green and red bottle, a courteous manner, and a certain skill in capping a one-and-a-half ounce phial brought in his income. Those days had gone by, and the success of each one now, wherever he might be, in London, in a country town, or in a village, depended on the ability with which he could apply the results of science. It was no use saying they had too much science, or too much of scientific men, they must have them, and they had better make peace with them at once, and take such help as they were prepared to offer.

Mr. Vernon Harcourt said he had no doubt that his name was coupled with the toast in consequence of his connection with a science on which pharmacy was so greatly based, having at present the honour of occupying the position of President of the Chemical Society. There was only one point in the remarks made by his friend Professor Michael Foster, on which he felt a little inclined to differ from him, and that was when he represented that scientific men were unduly critical one of another. Seriously that was not his view of the present attitude of science. He thought if scientific men had a failing it was rather the too ready acceptance of anything put forward by anyone in authority, and the too great readiness to model all they had to say and the theories on which their facts were to be hung according to that which was fashionable at the time. He thought it extremely probable that the many theories now accepted and considered necessary for the student, and even for the teacher, would in time to come be regarded by those who followed them in the same way as they now looked back upon the theory of “phlogiston,” something extremely difficult for a scientific man even to picture to himself as having entertained. He thought Mr. Foster would agree with him in saying that there was a danger on both sides, that whereas in particular cases they might be too critical, there was also a danger, and perhaps a greater danger, of their being too much inclined to follow in the steps of one another. He quite understood how the science of chemistry must be concerned in the practical services which pharmacists were rendering to their fellow-countrymen, and knew that the earlier part of the education of those present had taken place in the chemical laboratory. As the President had said he would particularly connect science with the teaching of science; he might add that that was the part of science in the pursuit of which the great part of his life had been spent. It was one of great interest, and a life might be spent not only in a pleasant but in a useful way in teaching the elements of chemistry to the rising generation.

Dr. Thorne Thorne, F.R.S., next proposed the toast of the evening, “Prosperity to the Pharmaceutical Society of Great Britain.” He said his branch of medicine was preventive rather than curative, and he had, so to speak, discarded drugs, but he must at once admit that he had not succeeded, and that the value of drugs and of therapeutics stood as high as ever it did. He would also point out that when he came to think this matter over the work of the Pharmaceutical Society seemed to form a link between those two branches of the profession, because whatever they could do with preventative medicine they were still obliged to come to the chemist for prevention as well as cure. At this time they had approached an era in medicine when they, perhaps, needed more than ever a scientific chemist and pharmacist. They were face to face, even in his branch of the profession, with the fact that there were certain micro-organisms of disease which attacked the human body, where they formed chemical poisons or toxins, which travelled, as it were, from one part of the body to another, and in remote parts and organs created mischief which was fraught with disease and death. They wanted, if possible, to trap these organisms and treat these toxins with what were called anti-toxins, and they were at the present moment seeing how they could in the first place prevent the multiplication of these organisms, and what to employ by way of anti-toxin, which should check the operation of these poisons, follow them, or even go before them, and so prevent mischiefful reactions, so that after all they came back to the chemical aspect on their side of the profession. When he looked at the Charter of their Society he found there were three things set forth: there was the protection of a honourable business, conducted by honourable men, a highly desirable object, but the founders did not place that first. Then there were philanthropic and charitable objects, but those again were not placed foremost, and the one thing which the founders of the Society placed in the foreground was the advancement of chemistry and pharmacy. At the present stage when they found the
enormous value of chemistry in connection with toxins and anti-toxins they might feel proud that their predecessors had such marvellous foresight, and looked forward to the day when chemistry in relation to bacteriology was likely to take so prominent a place, so that now in 1895 they were realising one of the primary objects which the founders had in view. He begged to couple with the toast the name of the President, Mr. Michael Carteighe, to whom might be applied the motto by which the ancients referred to the dead—nil nisi bonum.

The President, in responding, said Dr. Thorne-Thorne succeeded a man of very great eminence in Governmental affairs in relation to scientific pharmacy; he was probably a baby when Sir John Simon was ruling the Privy Council on all matters connected with public health. He was followed by Sir Geo. Buchanan, a man who in all his works showed that manly sentiment which all must respect. In fact, he was not sure that he was not too little too incisive in some respects; but, on the other hand, he did not see why a principal Medical Officer of the Government or any other person in a responsible position should be ashamed of insisting on certain views which he held to be for the welfare of the community.

The President again rose and proposed "The Guests," coupling with the toast the names of Dr. Burdon Sanderson (Regius Professor of Medicine, Oxford), Sir Dyce Duckworth, and Dr. Russell (President of the Institute of Chemistry).

Dr. Burdon Sanderson, in reply, said he had been engaged in teaching physiology for many years, and was now engaged in teaching what might be called elementary science. Their endeavour was to promote that science, and the University of Oxford had taken great part in the movement that was now going on for what was called university extension, which was nothing more than the teaching all over the country of elementary science. He entirely sympathised with the feeling that in that way only could education be really promoted. As to the special subjects of pharmacy and therapeutics he felt the immense importance of introducing more and more into medical education the study of pharmacology, or the thorough scientific knowledge of the modes of action of drugs, and in this line he thought they were doing the same work as the Pharmaceutical Society.

Sir Dyce Duckworth also returned thanks. He said he was interested in pharmacy as a member of the Pharmacopoeia Committee of the General Medical Council. With reference to that work thousands of recommendations were coming in on all hands from all sorts of persons who were qualified more or less to advise on the subject. As a somewhat old-fashioned person he ventured to put in a plea for the old-fashioned remedies. The best edition of the Pharmacopoeia in his opinion was that of 1851, for with every subsequent edition his sorrows had increased. He was old-fashioned enough to hope that they would not lose sight of many of those drugs which doctors had been accustomed to use, which experience showed had been of use, and he believed they would continue to be of use so long as medicine was an art.

Whilst they must not stagnate, but endeavour to keep progress with the advance of knowledge, at the same time they must not neglect those preparations for which they were indebted to the wisdom of their forefathers, which he believed would be useful for all time. Dr. Russell also briefly responded, and the proceedings then terminated.

BOTANICAL NOTES.

SENSITIVE MOVEMENTS OF PLANTS.—Dr. J. M. Macfarlane publishes the results of a series of experiments on the effect of coloured screens on the sensitive movements of leaves (Oxalis stricta, and several species of Cuscuta). He finds the exciting agents of the movements to be certain of the light-rays. When sensitive plants are placed behind coloured screens, the leaves fold up as in the nyctitropic state, most strongly under red, less so under yellow, only feebly or not at all under green light; while under blue screens the leaves remain open as in ordinary daylight. In all cases nyctitropic movements are accelerated behind a red screen, not quite so strongly behind a yellow screen, while behind a green screen the movements practically coincide in time with those of exposed plants, and are beautifully regular in sequence; under blue light there is a distinct retardation of the normal nyctitropic period. Up to 38° C., or even 43° in some species, heat-rays appear to fail in stimulating the tissues. The general result of these experiments is that the heat-rays, the less refrangible rays, and the more refrangible rays, are all efficient up to a certain point in inciting nyctitropic movements. Orange, yellow, and green screens to the protoplasm, whether in the form of pigmented walls, pigmented cell-sap, or chlorophyll, are of a protective character, and permit the normal functions to be carried on unimpeded by the injurious action of the more intense blue-violet rays (Botanisches Centralblatt, vol. lxxi., 1895).

AMOUNT OF LIGHT WHICH IS FAVOURABLE TO THE GROWTH OF PLANTS.—Hein. J. Wissner has come to the following conclusions on this subject:—Those plants which, like Lemna, receive an unlimited amount of light on all sides, do not produce a maximum of organic substances. In by far the greater number of plants the amount of light absorbed is diminished by the form and position of the organs. In trees this amount is reduced, in the peripheral portion of the foliage, to one-half or one-third, in the central portion to as little as one-eighth of the possible amount of light. All luxuriant vegetation is produced under conditions of comparatively feeble, and especially of diffused, daylight. Intense light is of no advantage to a plant growing in unfavourable conditions, especially in poor dry soil. Although the actual amount of light enjoyed by trees and shrubs is greater in tropical than in temperate regions, yet in the latter the leaves of deciduous woody plants receive a more intense light than those of the former at one particular period of the year, namely, at the commencement of the period of vegetation (Ber. Deutsch. Bot. Gesellschaft, vol. xii., 1894; General- Versammlungs-Hälf, p. 78).
The Pharmaceutical Journal
FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, MAY 25, 1895.

Editorial Department.

Communications for the Editorial Department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

Advertisement Department.

Advertisements and remittances must be sent to the Publishers, 6, Soho Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased. Cheques and money orders should be made payable to "Street Brothers."

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be addressed to the Secretary—Mr. Richard Bromidge, 17, Bloomsbury Square, London, W.C.

THE SOCIETY'S ANNIVERSARY.

The reports published in this week's Journal of the meetings connected with the annual celebration of this event are so full that it is unnecessary in this place to do more than refer to some of the more salient points of the proceedings of the past week. Among these it is especially satisfactory to note the continued and increasing interest taken in the Pharmaceutical Society and its work outside the ranks of those actually engaged in the practice of pharmacy. This is evidenced not only by the presence at the annual dinner of distinguished guests representing Government departments, Parliament, science, and the learned professions, but also by the appreciative remarks made by them in responding to various toasts. No better proof could be furnished as to the utility of the Society's work and of the fact that its beneficial influence in regard to the interests of the public has been very generally recognised. This circumstance should serve as a satisfactory answer to the somewhat disheartening questions sometimes heard within the pharmaceutical body as to the usefulness of the Society and the need for supporting it as a representative organisation. In this connection it was matter for congratulation to hear a prominent official connected with an important State department speak with emphatic approval of the constitution and objects of the Society, and it was no less satisfactory to find the head of another great State department—impressed with the intimate relation existing between it and every kind of industrial occupation—interesting himself as to the particular nature of that relation which obtains in the case of those engaged in the practice of pharmacy, and seeking for information on that point. The sympathetic expres-

sions of eminent representatives of science and of the medical profession in regard to the Society's educational work, and its participation in the task of pharmacopoeia revision, were also proof that the advance towards improvement effected through the medium of the Society, in the qualification and position of the pharmaceutical body, has been recognised and appreciated in such a manner as to be of practical value.

The subjects discussed at the Annual Meeting were less varied than on some previous occasions, though the Council report referred to several of great immediate importance. In the President's résumé of the report attention was prominently directed, retrospectively, to the legal decisions as to the construction of the Pharmacy Act, and prospectively to the impending revision of the British Pharmacopoeia, as well as the possibility of amended legislation in regard to weights and measures. Subsequently, in reply to the remarks of Mr. Campkin and Mr. Mackenzie on further pharmaceutical legislation, the President stated that the subject has been under consideration, and will, no doubt, be reported upon when the new Council meets. The question to be settled relates mainly to the scope of a Pharmacy Bill, and whether any attempt to deal with the evil of company trading should or should not be made at the same time as provision for consolidation of the Society. While a demand is being made for legislative protection, the fact is lost sight of by many that only a very partial advance has been made towards a professional position which would justify that demand. Even in the case of the medical and legal professions efficient power to protect the interests of their members is rather the result of internal organisation that of legal enactments, such as the Apothecaries Act, which are at best difficult to enforce, and, to a great extent, little more than theore
tically restrictive. The existing necessity for registration from the point of view of public interests, affords a valuable basis for protective organisation of chemists and druggists; but for carrying out any scheme that would secure greater protection of their trade interests it would be essential to adopt various self-denying ordinances to which many of those engaged in the business are not disposed to agree, or could not at present bear.

ELECTION OF COUNCIL.

The counting of the votes recorded in connection with the election of the Pharmaceutical Council was proceeded with on Thursday last, and the result announced at the adjourned general meeting on the afternoon of that day. Particulars are published at page 1075, and it will be seen that all the retiring members who had accepted nomination have been returned, together with Meers. Corder and Savory.
NEW SERIES OF THE JOURNAL.

In a few weeks the Pharmaceutical Journal and Transactions will have existed for fifty-four years, and will celebrate its twenty-fifth anniversary as a weekly record of the progress of pharmacy in general and of the proceedings of the Pharmaceutical Society of Great Britain in particular. Originally a private venture, it was edited during the first eighteen years of its existence by its founder—Jacob Bell, under whose fostering care it gradually became “a vehicle for the publication of all the progressive improvements and discoveries in pharmacy and the sciences connected with it, in addition to such elementary and practical information as is likely to be useful to the student” (vide Preface to the Third Volume). The Transactions of the Pharmaceutical Society formed a distinct portion of each monthly number, but the greater portion of the space available was occupied with matter which was dealt with from a perfectly independent point of view, in this first series of the Journal. At Bell’s death in 1859, the Journal became the property of the Pharmaceutical Society, and naturally assumed a more pronounced official character, certain changes being found desirable as a matter of expediency. The intervals of publication were not altered, however, and the Journal was conducted on much the same lines as formerly, until the conclusion of the second series in 1870. In July of that year commenced the publication of the Journal in a new form and as a weekly periodical. It was enlarged to its present size, and has ever since continued to deal with a greater quantity and variety of matter.

Concerning what has been accomplished in the last quarter of a century it is needless to say anything at the present time, but it is interesting to recall the words (vide Introductory Article, July 2, 1870) in which it was imagined that Jacob Bell might fitly have apostrophised British pharmacists at the time the third series commenced. “Love of science has increased immeasurably in the minds of chemists and druggists, let the special sciences of our trade have due space accorded to them; but fail not also to remember that we have still a trade to care for, and let not the questions concerning that trade be overlooked.” With regard to this point it has been felt for some time past that the lines on which the Journal was being conducted did not sufficiently meet the requirements of pharmacy as a trade. This was not the result of any change in the principles on which the subject matter had been selected during so many years, but rather on account of a development in the ideas of readers with regard to what they considered necessary; whilst, therefore, endeavouring to fully maintain the character of the Journal as a faithful record of progress in pharmacy and the sciences of which a knowledge is essential to a proper acquaintance with pharmacy, an attempt has been made during the past few months to ascertain in what respects change or alteration might be desirable.

As a result of this experiment, it has been decided to continue much of what has so far been tentative only, and it is thought that this affords a favourable opportunity for beginning a new series in which important changes may be effected. Accordingly, the Journal, of which the title will henceforth be abbreviated to the Pharmaceutical Journal only, will appear on July 6 next with pages of larger size than at present and new type. Two volumes will be completed during each year instead of one, as at present, thus obviating the tendency to excessive bulkiness when bound. This alteration will have another effect of greater importance, viz., that of reducing the time during which an index is not available for the current volume by half. As regards contents, they can only be referred to in general terms. Whilst scientific matters will continue to be regarded of as great importance as heretofore, professional and trade interests will also receive the fullest possible attention. Pharmaceutical students will continue to receive as much consideration as at any time during past years, and subsidiary matters of interest to pharmacists will be dealt with from time to time. The news element, so important a factor since the advent of the newer journalism, will not be neglected, for securing the success of this depart the Editor hopes to obtain assistance from members and associates of the Society throughout the country by the forwarding of any items of interest with which they may become conversant. This suggestion is made with the idea that the members and associates should recognise in the Journal a co-operative undertaking, in which they are virtually shareholders, and as such especially interested in its success. In conclusion it may be stated that, with a view to making the proposed changes known as widely as possible, the first issue of the new series will be sent to every chemist in business in the United Kingdom, as well as to a large number in the Colonies, India, the United States, etc., the total circulation on this particular occasion being expected to exceed 16,000 copies.

CHEMICAL WORKS INSPECTION.

In his annual report for 1894, Mr. C. E. FLETCHER, chief inspector of alkali works, says the number of works now registered in England, Ireland, and Wales under the Act is 1056, of which 102 only are alkali works proper, while 954 come under the schedule of other works which have more recently come under its provisions. These numbers show an increase of one alkali work and of nine other works since 1893. The number of visits paid by the inspectors to the works is irregular, and depends on the pressure there carried on, and the usual condition of the work. When there is no apparent need for repeated visits they are made about once a month. The kind of examination varies in the different works. In the case of the alkali works there is a limit laid down of the amount of muriatic acid gas which may escape without contravening the provisions of the Act. The amount may be stated either in relation to that being produced at the time, or absolutely in grains per cubic foot of the escaping gases. In sulphuric acid works also a definite limit is fixed. In other cases the provisions of Act are complied with if the best practical means have been employed to prevent the escape of noxious gas.

LIST II.

ADDITIONS.

Articles and preparations the Addition of which to the British Pharmacopoeia is recommended by the Pharmacopoeia Committee of the Pharmaceutical Society of Great Britain.

Acidum Hydrobromicum, sp. gr. 1.498

Adulterated Hyposphosphate

Ammonii Iodidum

Benzonaphthal

Brominated Balsam

Caffeinae Otras Effervescentes

Hydrobromat

Carbasi Hydr. et Zici

The President moved that the report and recommendations of the Pharmacopoeia Committee be received, and that the result of the Committee's work be communicated to the Pharmacopoeia Committee of the General Medical Council, in accordance with the terms of Sir Richard Quain's letter of December 12, 1894.

The Vice-President seconded the motion, which was carried unanimously.

RESTORATIONS TO THE REGISTER.

Certain members who had neglected to pay their subscriptions within the prescribed time, but had since done so, were restored to the register.

The Council then arranged the order of business for the annual meeting, and then adjourned to the annual meeting.

FIFTY-FOURTH ANNUAL MEETING.

The fifty-fourth annual meeting was held on Wednesday last at 17, Bloomsbury Square, W.C., Mr. Michael Carteige (President) in the chair.

The notice convening the meeting having been read, the annual report (ante, p. 993) was taken as read.

The President said: "Ladies and Gentlemen, it is my duty as well as my privilege—to after so many years I do not know that one can consider it a pleasure—to present the annual report to the members. The paragraphs in that report do not require very much expanding on my part, as I think they speak very largely for themselves. In the first place I may refer to the fact that we have been spending some money, as you observe, in Scotland, but we feel that all those who are associated with us in the Society will approve of that expenditure, insomuch as the premises, on which a comparatively large sum has been spent, and some more is to be spent, are now admirably equipped for the special part of the Society's work in Scotland. We exist, as you know, for two purposes. First, we are a voluntary Society, and have to do various matters in that capacity; secondly, we are practically a department of the State endowed with duties with regard to examinations, and it is our duty in the latter capacity to see that the examinations under which our examinations take place should be such as should commend the report to the public and the approval of the Privy Council. Therefore, in adding to the Society's rooms in Edinburgh, in giving them facilities for practical work and a large Board room for the meetings of the Board, we have done something which I conceive to be our duty for the proper conduct of the examinations. Anything additional we have done, or may do, will be for making that house in Edinburgh as well fitted for the general purposes of pharmaceutical business as possible. I take it that no member of this Society would approve of an expenditure which would tend to show to everyone in Edinburgh and London that the Pharmaceutical Society of Great Britain is a living concern, that it has a house to keep, and that the house, whether in Edinburgh or London, is kept in good order.

EXAMINATIONS.

I have nothing to say on the subject of examinations at the present moment. The conditions under which the examinations have been conducted during the last two or three years have been somewhat different from what they were formerly, and I am in hope that when once the candidates get to understand the nature of the examinations—some of you may smile when I tell you that they have not yet altogether got to understand it; in time they will get to understand it, sometimes by failing, amongst other things, but when they do understand the nature of the examinations and the necessity there is for spending a proper amount of time and money before presenting themselves—the whole system will work well, and will fail in fewer failures. It certainly is not a pleasant thing for anyone occupying my position to have to call attention to the number of failures.

REVISION OF THE B.P.

With reference to the Pharmacopoeia Committee, it is known to most of you that the Medical Council has to take the necessary steps for producing a new Pharmacopoeia, that application has been made to the Council of our Society for assistance in the matter, and that a committee has been formed for the purpose of gathering the necessary statistics, and so on. The precise form in which the Society will eventually be asked to give its assistance we, of course, do not yet know; the matter, I believe, will be discussed at the meeting of the General Medical Council, which takes place next week, and probably some propositions may be sent to us, and something practicable may be put before us to do, or some investigation may be sent to us eventually to be made with the view to producing the necessary material for a new volume. You will remember also that it is proposed to add another volume to the Pharmacopoeia one which shall be national in its widest lines—imperial in fact, covering Canada and the whole of the British Empire. It may turn out that the sanguine expectations of some members of the Medical Council, and notably those of
Professor Attfield, may not be quite borne out by the facts; there may be more to do than they suspect and that may involve that may involve that which is ever more to do on our behalf that what ever help is required in the production of this volume, whatever may have been from time to time our criticisms on that volume, the Council of this Society, through the solicitor of the Council in its duty to do, everything to assist the Medical Council in producing a satisfactory Pharmacopoeia!

LEGAL BUSINESS.

Now, gentlemen, the paragraph in regard to law proceedings is one that I think is my duty specially to speak to you about at this meeting. It refers very specially to two particular cases. The case of Amronson, in which there was an appeal against the decision of the Court of Appeal as to what is a statutory poison, viz., how much poison comprises within the meaning of the word "poison" in law. At present I think I may say it seems to me to be about one eighth of a grain of morphine per os.; that is what it comes to. Amronson sold a proprietary preparation which I must not refer to because it might be libellous. His case was fought out, as most of you may know, with an interest in the matter, and carried to the Court of Appeal, which not only carried to the Queen's Bench, but on to the Lords of Appeal, and those of you who have not read the judgment given by those Lords of Appeal I think would do well to turn it up and read it. I think you will see in the judgment of the Master of the Rolls and of the Lords justices a number of useful opinions which point strongly to the fact that the Society is doing its work well, and that we are justified in seeing that the law is obeyed with regard to the sale of articles containing comparatively minute quantities of poison. One thing which that judgment shows more clearly than another is that in law our term "preparation" does not seem to mean much. If you sell a poison mixed with water or anything else you sell the poison. Therefore, I think we may dismiss the word "preparation" in fact. It has been a stumbling-block not only to lawyers but also to the President, and I am very much more used to the Lords justices personally as representing the Council, because they have facilitated our work very materially. They have practically laid down the dictum which seems to be borne out every time one comes in contact with lawyers, that whether you sell morphine mixed with treacle or dissolved in water, or in any other way, you are not selling in law a preparation of morphine, but you are selling morphine. From the point of view of this Council it is a dictum which is extremely convenient. Of course it has other consequences; it has this important consequence that in the schedule where the word "preparation" does not now appear all those of us who are registered must bear in mind that we are within the meshes of the Act if we do not attach a proper label to a mixture of particular substance (which has not the word preparation after it) with other ingredients. I know there are some of my friends who think that that the word "preparation" does not appear after a poison named in the schedule that they are not selling a poison when they are selling a mixture. I am bound to tell them that from a lawyer's point of view that seems to be wrong, and that when we sell a mixture of a substance which has not the word preparation after it in the schedule we must be prepared to regard it as a poison. To take an illustration, I am not sure—I am speaking from memory—but with regard to the word "corrosive sublimate" I do not think the word preparation follows. But wherever the word preparation does not appear in the schedule it nevertheless is the fact that if we sell what we as druggists call a preparation of that poison we are selling poison, and therefore we are liable to the law. I do not refer to the matter now to say that I am sure you will allow me to state on your behalf that whatever help is required in the production of this volume, whatever may have been from time to time our criticisms on that volume, the Council of this Society, through the solicitor of the Council in its duty to do, everything to assist the Medical Council in producing a satisfactory Pharmacopoeia!

Weights and Measures.

Now with regard to weights and measures. There is a paragraph in the report on this subject, which I only refer to now because it so happens that I was summoned yesterday to give evidence before the Committee, and the reports that are given of such evidence are, of course, generally very brief, and it is very right and proper I should say substantially what took place yesterday. The Committee appears disposed to con-
Losses of the Society by Death.

Then, gentlemen, we have to note the loss of one or two distinguished men, Flickiger, Bommer, and Ferrein, of Moscow, who were honored members and corresponding members respectively. Flickiger, as you know, was the companion and fellow-worker of Hans-Burchard, and thus made the Correspondence of the Journal and of members of the Society. Perhaps one of the most pleasant things that has occurred recently in connection with the death of one of our corresponding members is the fact that the widow of Mr. Ferrein, of Moscow (who was only made a corresponding member last year), was able to receive on her behalf, and send to the society, the funeral expenses which she had paid for. It is a great loss to Moscow, but this particular pharmacy is a historic house, and one of considerable importance and dignity. Then we have lost, as you know, a number of founders--Edwd. Horner, J. Beech, Wm. Hooper, and Wm. Darling. We have also lost our old friend, Mr. Savage, formerly a member of Council. I need not consider him as an elderly man; I first knew him about thirty years ago, and it is most remarkable to find that he lived until so recently. We have also lost a certain number of local and divisional secretaries. The number of founders, of course, is diminishing, but it must naturally be, but I am glad to know that there is one more at all events than the number I referred to the other day at the Council, for I understand that there are a certain number of associate founders who became members in after years whose pedigree, if one may use the expression, was not always kept in the archives of the Society. I say that just as a sort of apology if there happens to be a number of founders living than I referred to the other day. I know of one, and probably that gentleman is present, and may refer to it. There may be other members in the Society who joined as associates and became members many years afterwards, the fact of which is not always known to us. If any of those associate founders will communicate with the Secretary we shall be glad to place their names on the list, which I venture to think will become more and more honourable the smaller it becomes. The resolution I have to propose is, "That the report of the Council be received and adopted." Vice- President has dealt with the items in the report so fully that it would be foolish on my part to attempt to enlarge further upon them. I will content myself by simply seconding the motion.

Mr. Butt: Mr. President and gentlemen, we have lived together in a great deal of pleasure to the manners in which the President has amplified the report which has been put before us. No man is more capable of dealing with matters pharmaceutical than our worthy President; as he just reminded us it was some thirty years ago since he first came upon the scene. In the early days when I was a member of the Council, in those stern times which existed about the time of the passing of the Pharmacy Act, Mr. Carteigh got initiated into the world of Society under that admirable past president our late friend Mr. Geo. Webb Sandford. On the passing of the Act Mr. Carteigh retired from his position as a member of Council, and instead of office, and it fell to a great extent on his shoulders to organise the system of examination which has been carried on by this Society ever since the passing of the Act. After some ten or twelve years as an examiner he retired from the Board of Examiners, and was elected a member of the Council,
and for the last thirteen or fourteen years he has been President of the Society. During those thirty years there is no man who has done more to advance pharmacy than the President. No man has given up more of his own time to the interests of others; there is no man who has ever been connected with the Pharmaceutical Society who has been more intimately connected with pharmaceutical politics than Mr. Carteigh. Even our founder, the late Jacob Bell, has not done half so much for pharmacy as Mr. Carteigh, and I am quite certain that all of you gentlemen will give your best thanks to Mr. Carteigh, our President, for the services he has rendered to this Society.

I now propose to proceed to another subject, and with your permission will refer to one of Asop's fables, called "The Mountain in Labour." The gist of this fable is in its application. Persons of all kinds who raise the expectations of mankind, and then by their mean performances betray and disappoint them, have the same name as is bestowed upon the authors of this fable. I now propose to deal with some facts in connection with the Research Laboratory, to which the preceding fable seems to me a fitting prelude, and I propose in my remarks to divide the subject into two parts.

First, I propose to point out the object with which the Research Laboratory was established, and next to show you how much of the work that laboratory was established for has been done. In doing that I cannot do better than read several extracts from the Council meetings as reported in the Pharmaceutical Journal, principally from speeches made by our worthy President. At the Council meeting which took place ten years ago, two subjects of systematic pharmaceutical research were introduced to the Council by the President, and in the course of the remarks he made he said: "The Society had for a number of years promoted education, and had indirectly promoted systematic research." There was a large field of research in connection with the effects of medicinal drugs. "The effect of different substances on the commonest drugs had been very little investigated." Again, "the best way of dealing pharmaceutically with a new remedy was an important question." Again, "it had often been held that to keep a Pharmacopoeia abreast of the day it was essential that the work not be done continuously. The moment a new Pharmacopoeia appeared it should be the duty of a permanent committee to consider it, and see how far its processes answered, what was intended, how far it could be improved, and how far in some cases they could be eradicated." "They might be content the first year with organising a system of efficient workers at a comparatively small expense, directed by a competent person filled with sufficient enthusiasm for the work, and rendering themselves useful not only to the members of the Society and the public, but also to the public at large. If such a project could be carried out with spirit the Pharmaceutical Society might in the future be referred to on all matters connected with the analysis and impurities of drugs. He did not mean that they should undertake ordinary analysis of drugs, but the work under the superintendence of the Council, to produce an effect on the public which would be of extreme value, and the benefit in the improvement effected in pharmaceutical processes must produce an effect on the medical profession and on the Medical Council which could not fail to be beneficial."

If this were done "the general result would be that after ten years the amount of weapons which would be necessary in the shape of drugs and preparations for the cure of disease would probably be materially reduced to nothing, whilst the potency, applicability, and value of those remaining would be proportionately increased. In the case of new preparations, their value would be discovered, and to what extent they were of value, and thus the compilers of the National Pharmacopoeia, and the Pharmacopoeia of this country, would be placed at their command which they could not afford to neglect." After a long discussion the following resolution was passed:—

"That the Library, Museum, and Laboratory Committee be instructed to consider and report by what means, if any, systematic research in pharmacy can be promoted by the Society, and report to the Council." In December, 1885, six months afterwards, the Committee reported to the Council that the question of the encouragement of systematic research in pharmacy had also been considered. The President, in moving the adoption of the report, said the investigations to be carried out in the laboratory must consist of two parts: the research to be conducted on the natural history, chemistry, and pharmacy of drugs now sold, in a complete research on the aconites or belladonna, as well as the complete investigation of new drugs which had acquired a certain amount of reputation, but which had not been scientifically investigated. Second, by second means of verifying and practically testing the various formulæ of the British and other pharmacopoeias. This was just an outline of the way in which such a laboratory would be useful. He would remind the Council that there was no authoritative decision as to what citrate and iron and quinine was, and other matters of the same kind, which I will not enter into. The result of that was that the report and recommendations were referred back to the Committee for further consideration. In March, 1886, the President, in moving that the report and recommendations be received and adopted, said "he had on a former occasion pointed out some of the advantages which he thought would accrue from such a laboratory, amongst others that there would be an opportunity of repeating, from the point of view of pure pharmacy and chemistry, experiments having for their object, amongst other things, the improvement of the formulæ of the British Pharmacopoeia." Mr. Hampson said that the money of the Society could scarcely be spent for a better object if a commensurate result could be assured, but he was not satisfied that that would be the result. If pharmacists had the preparation of the Pharmacopoeia once more in their hands then they might begin work at once; but the Society had not as yet received recognition by the Medical Council or the Government in dealing with the Pharmacopoeia. Perhaps starting this laboratory might be a means to that end, and if so he should be very glad to support it. Mr. Schacht said "it occurred to him there was scarcely a word on the subject about publication; there was a limit as to what should not be published, but there was scarcely a sufficiently strong declaration that all the work of the laboratory should be published." The motion was then again referred back to the Committee.
because in the Pharmacopoeia some of the more active preparations had been standardized; but the conclusion remained that whenever a research laboratory was thought of, it was necessary to be thoroughly assured in the minds of all that the project was distinctly pharmaceutical. There were other bodies from whom they could get valuable biological, chemical, botanical and other facts; which might be deeply interesting to them; but as pharmacists, in their own laboratory, they should take care to spend their material in their own business. At the Presidential dinner the President reminded the Council that this subject had been under consideration between two and three years.

"The intention of the resolution was to work on the lines of the scheme which Mr. Crose preferred."

This was the resolution that the sum of £300 a year be granted for the next three years to a committee to be appointed annually, and that arrangements be made which will enable advanced students and others to undertake pharmaceutical research. The scheme was drafted as to the lines on which research was to be carried out. Pharmaceutical research should be directed to promoting scientific knowledge and would consist of the following duties:—The revision of all existing pharmaceutical preparations; and, conjointly with this—first, how far various preparations represent the drugs from which they are derived; what are the qualities of the drugs and the relative value of leaves, roots, seeds, etc., with many other matters of a similar kind.

I have given you now a short history of what the Research Laboratory was established for—pharmaceutical research. The resolution which was passed was a resolution to establish a laboratory for pharmaceutical research. I will now point out to you how much of that work has been done. In March, 1889, the Research Laboratory Committee reported to the Council, and they began by stating that the laboratory was established to undertake pharmaceutical research. Then in February, 1890, the Committee again reported on the same subject. In February, 1891, the Research Laboratory Committee reported to the Council, and gave a résumé of their work for the previous three years. Twenty papers were referred to in that report. Of those thirteen only were obtained from the Research Laboratory, seven being obtained from the Chemical Society, and eleven only were read at evening meetings, one before the Royal Society, and one before the Chemical Society. In the first three years the Society voted £300 a year, and in addition to that, for a portion of the rates, rent, and taxes, water, gas, depreciation, and so on, you may easily add another £300 a year to the amount. Now we come to the second period, the last four years, during which the Research Laboratory has ceased to be a pharmaceutical research laboratory, and become almost entirely a chemical research laboratory. The papers have not been read before the Chemical Society. The Research Laboratory publishes such very eminently scientific papers that they are not fit for the ears of ordinary pharmacists. They have to take them to some other place where a more appreciative audience can estimate their value. Out of a total of twenty-five papers only four were then read, and none of them were very few reported in the Journal. Thirteen were referring to aconitine; five, I think, had reference to purely chemical subjects, and I understand had been for by a grant from the Chemical Society. I do not think the Research Laboratory was established to do the Chemical Society's work; it is not for that purpose. The Research Laboratory is not a worker, and we cannot afford to keep an ornamental individual with the title of Director of the Research Laboratory who does nothing but misdirect. What we want is a person who has a knowledge of pharmacy, who knows what the requirements of pharmacy are, and who has sufficient chemical knowledge to secure enthusiasm for his work to conduct our Research Laboratory on the lines on which we have always supposed it would be conducted. We want a man who has not fifty other engagements, or even twenty, but a man who will devote his time to the work for which he is paid, and not have those engagements to discharge in the evening meetings. Subsequently for the last four years they have been all read before the Chemical Society, as I mentioned before. If the work which has been done in the Research Laboratory of the Pharmaceutical Society had been pharmaceutical research, the proper place to have read those papers, and to have commented on them would have been in this room. The circulation of the Journal of the Pharmaceutical Society is considerably larger than that of the Journal of the Chemical Society, and not only that, but the work done there and for which we are paying would have gone to those who would benefit by it.

The work which has been done during the last seven years has been of no value whatever to the Pharmaceutical Society, with one or two very trifling exceptions. The Research Laboratory, has been carried on during the last three or four years at very heavy cost in some respects. The money expended at the present time directly and indirectly is not less than £1000 a year. Now, if the Director of the Research Laboratory had thought proper to fit out an expedition to the North Pole and had discovered that very interesting object and brought back a full account of the fauna and flora of that interesting region, no doubt they would have obtained a very great amount of kudos, but I should have said, and I think you will all agree with me, that the money of the Pharmaceutical Society had been appropriated to purposes for which it was not intended. The way in which the money has been appropriated for the last four years has been equally a misappropriation. No doubt a certain amount of kudos has been received, and I do not mean to say a word, or very little, against the work which has been done, but it has been done in a wrong direction; it has not been pharmaceutical research, but chemical research. The case is precisely the same as if the new Council most strongly to take the very first opportunity to remove the present Director of the Research Laboratory from the post which he holds, and replace him by a person more competent and capable of doing the work for which that laboratory was established. The President said, when it was proposed that the Research Laboratory should be established, that in ten years we should accumulate a sufficient amount of facts so that the Medical Council could not afford to ignore us. How many facts had we accumulated in the last seven years? Not one, and if we had not the work of the Pharmaceutical Society is published, whether it be in seven, or ten, or twenty years' time, we shall not have accumulated one more fact than at present, and the editors of the Pharmacopoeia will not derive one atom more benefit from the work of the Research Laboratory in the future than they have in the past seven years. If I may, I say you must remove your Director, and replace him by a person more competent to do the work.

There is one other matter which I am sorry to have to refer to, the question of the reliability of the work which has been done in the laboratory. I have very great doubt whether the work which is there carried out be of that character which we are in a more or less careless, slipshod, perfunctory manner— that the Director himself knows little about the
work which is done, but is dependent entirely on what he is told by those who work under him. I will give you one or two instances. With regard to the papers on piperoxane and pellotoline. I had great difficulty in finding out what the professor was really after seeing an abstract; and, instead of giving definite results, the Professor reported—"Piperoxane appears to possess an alkaloidal character." We do not want to know what anything "appears" to possess; we want some definite conclusion. With regard to pellotoline, he said most of its chemical and physical properties closely resembled amylic alcohol; in order to reach this conclusion he exhibited certain small differences, which may possibly disappear when the substance has been further purified." Why waste time, gentlemen, and allow your Director to waste time on research on impure substances! Purify your substances before you commence your research, and then probably you will come to some definite conclusion. But if you are dealing with an impure substance, how can you arrive at any definite conclusion? Anyone can work on impure substances; it does not want a research laboratory for that. We want from a laboratory the Society of the Royal Society.

Another question taken up is that of aconitine. Thirteen papers were read on aconitine, and the work done, as I believe, has to a considerable extent been paid for by the Royal Society. Groves worked at that many years ago; Mr. Williams, our late President, worked on it; Wright and Luff worked on it; Dunstan has worked on it. And what is the result? Have you discovered one single thing in the whole history of the research which is of the very slightest benefit to the medical profession or to the dispensing chemist. You may have, from a scientific point of view, discovered certain facts which may be very interesting to chemists. And yet, so far as I know, no researches are reserved for bodies like the Chemical Society or the Royal Society, if they choose to establish research laboratories of their own. It is not work of ours; we cannot afford to waste four years of our time in investigating one substance, and then arrive at no conclusion except a controversy. I was speaking just now about the reliability of the work. In the report for 1892, there is this very distinct and definite statement:—"Napelline or isaconitine possesses the same chemical composition as isaconitine, and furnishes the same hydrochloride as the latter. We believe the statement is wrong, or else a statement that has been published recently is wrong. They do not agree. We are distinctly told now that aconitine, when hydrolysed, loses acetyl and what was known as isaconitine is formed, which is an entirely different process.

Into this aconitine controversy I will not enter; it is very much too long and very much too difficult a subject for us to understand. Whether Professor Wyndham Dunstan has stolen Freund and Beck's thunder, or whether they have stolen his, is more than I can tell, but of one thing I am absolutely certain, and that is that Professor Dunstan wrote to the Chemical Society of Berlin in February of last year, claiming priority of the discovery that the constitution of aconitine was acetyl-benzoyl-aconine, and the so-called isaconitine was benzoyl-aconine. He said this had already been published by him, and when he was asked at the first stage how he had now arrived when you should pass him on, and the sooner you pass him on the better. At the last Council meeting—I am going to trouble you with only a very few words more—someone was enquiring about the expense of the Research Laboratory, and particularly with reference to a grant from the Chemical Society, the President said: "With regard
to the special chemical paper, a grant was made to Professor Dunstan by the Chemical Society, and he asked the Committee whether they would like the name of the Research Laboratory used in connection with it, and it was thought desirable that it should be so connected; otherwise Professor Dunstan would have to find the money. He has no time whatever to carry out investigations on behalf of the Chemical Society, excepting in our Research Laboratory, and at the expense of this Society. I want this Research Laboratory conducted on proper lines where we shall do our own work, and will have the benefit of the research work of other people. Last year it was my intention to have brought this subject before the meeting, but on speaking to two or three of my friends I was deterred from doing so. I was deterred on the ground that it was not fitting to wash pharmaceutical dirty linen in public. But there has been so much pharmaceutical dirty linen washed of late, and hanging in rags and tatters on the line, that nothing I can say can add anything to the laundry bill. I thank you for having listened to me so patiently.

Mr. MACKENZIE said he had attended during the last twenty-three years a number of the annual meetings, but he had never attended one that had been led off in the way the present one had been, or where the members had been entertained in the way they had been on the present occasion. The first speaker began by eulogising the President, but ended very differently, in fact, he (Mr. Mackenzie) thought they ought not to have listened so long as they did to an attack on a man who was not present to defend himself. When a gentleman was not present to reply to an attack, it was not honourable conduct on the part of any one to attack him in the way it had been done. Leaving this subject, he should like to say a few words upon the report, and in doing so would touch upon what had been said, though he would not occupy the time of the meeting at any great length. As one of those who had stated on many occasions hard things against the Council, he was present that day to state how much he appreciated their worth. The Council had realised that if they did well for Scotland they would do well for themselves. He would not say that the Council had cast bread upon the water, but he would say that they would reap a rich harvest before long. He was glad to think that the examinations were now being conducted on good lines, and he was glad they had nothing to be ashamed of in Scotland, and he hoped the time would come when they would react, so as to be a great benefit for the future of the Society. He could only assure the members that those in Scotland appreciated what had been done for them by their friends in London. He hoped the Council would never lose sight, in any bills which they might be promoting, of the fact that only those who were upon the Register ought to reap benefit from trading. This was the axe which lay at the root of the whole tree. In his opinion they were clutching at straws while letting whole bundles of sticks go by. At the present time stores and limited companies were doing what only qualified persons should be allowed to do. Not long ago there was a talk of the great advantage of clumping trees, and he fancied this idea might be held of the present way of drawing up the balance-sheet, for many of the items were so clumped together that it was impossible to understand them. With regard to the Research Laboratory, he thought as business men they were not prepared to spend a large amount of money without obtaining some result. He had every confidence in those who established that Research Laboratory, believing their aim was right in the beginning and that they intended well, and he felt sure the time would come when the result of the labors of the Committee would turn out valuable and be applicable to things of daily life. If humble things were dealt with he believed great things would be achieved.

Mr. CAMPIN: If I am in order I should like to ask a question on the section of the Report which refers to the Pharmacy Bill. I should like to ask the Council, although it has been described to-day as being in a "moribund" condition, to give some indication as to when we may look for further action or for anything in connection with legislation during the forthcoming Session of Parliament. It is well known to those who have anything to do with Parliamentary Committees in their own towns or corporations that in order to secure attention to a bill it must be deposited by the latter part of the year. Of course, legislation is out of the question in the present Session of Parliament, that we quite understand, but at the same time I should like to know that the present Council have not lost sight of the necessity probably for legislation, and assuming they believe in further legislation, do they believe that inasmuch as a draft bill was submitted to us at our last annual meeting, upon which no further action was taken; but assuming they are of opinion that that draft bill should be continued and supplemented, as many chemists in various parts of the country think, although the bill was good as far as it went, still it might be considerably supplemented. In such event it might be necessary to consider the question forthwith, in order that a draft bill might be submitted at the end of this year, which would be considered in Parliament next year. If that be so, would the Council of the Pharmaceutical Society be prepared to bring members thereof into their confidence previous to submitting the bill, because there are very many important questions that are vexing the pharmaceutical mind throughout the length and breadth of the country and with which the draft Bill of last year did not probably deal. I believe that Bill dealt to a large extent with the formation and the reorganisation of the Society, or the Council of the Society more particularly, but there are other matters upon which legislation is believed to be necessary. Legislation with regard to the Council of the Society is probably necessary, and he would to that extent, if good classes of the members thereof upon the Council of the Society, because at the present moment the more numerous body of members are practically not in a position to be directly represented, and I believe that alteration was contemplated by the draft Bill. But it is not only a question of the representation of the Society, but other matters, in order to secure that position which the Pharmaceutical Society should attain in the country generally; it should be made far-reaching, and I think that in any effort for legislation we should be able to say that we represent the entire trade. Then perhaps we could go to Parliament, knock at the door of Parliament, and that door may be opened to us. At the present time it may be that the Society, although considered a representative Society still, is not sufficiently inclusive. We want in any legislation to get the representatives of the Pharmaceutical Society inclusive of the whole of the trade at large. That opens up the large question of the question of proportion (and we have heard so much this morning of the Research Laboratory) for the trade itself with regard to higher examinations. That opens up a very wide question. And the question is being asked from one end of the country to the other,—When
you have secured this higher education, and assum-
ing that every future entrant to the Society becomes fully qualified in every exam-

Maior certificat, what is to be done with him then? 

At present a gentleman with a Major certificate has 

very little protection indeed, and in view of existing 

company trading he is no better off than the grocer 
or the stationer who sells drugs, or the gentleman 

who is a capitalist and invests his money, 

although he is a graduate of the University of 

Cambridge, and who have no business and are ordi-

nary business entirely disconnected with pharma-

cy, and though he can put his money into a 

concern, and by that means amass a considerable 

fortune for himself and those who think fit to join 

him to the eventual utter ruin and annihilation of the 

members of the craft. It is not for me to foreshadow 

in what way you, or those who are associated with 

you—because you will be called upon to take part in 

future legislation with regard to the Society—or to 
dictate to you as to what course you shall adopt; 

but there is a great and general outcry on behalf of 

pharmacists throughout the country at the present 
time on account of the utter absence or protection 

for them after they have gone through this long, 
tedious, and expensive course of training. They do 

claim that in any future legislation they should 
have the same protection as is afforded to members of 

other professions. We know perfectly well that the 

members of the Incorporated Law Society have 

nothing to fear from outsiders; and the mem-

bers of the medical profession, who after all obtain 

their degree and other qualifications at no greater 

cost in proportion than the members of our own profession, because it is a question of 

degree after all, are protected, and we ask that 

in future legislation the chemist should be pro-

tected. At the present time, after the Major qualifica-

tion is obtained, what is the position of the holder 
in many of our districts? A young man goes down 
to take a business, where he is under the necessity 

of selling oil, colours, paint, and many other things quite out-

side pharmacy, for the very reason that he has not 
an opportunity of doing much else; he is over-

shadowed by the great stores conducted by 

utterly irresponsible persons who are outside the pale 
of the trade itself, and who just bring themselves 

with the degree and no qualification into the 

stores who has the necessary qualification. Of course the question is, what is to be asked of those 

who lend themselves to that position, who sell themselves to that position — to those who have obtained the Major or Minor cer-

cificates? I would ask this question: In so doing and 

in furthering as they have done the store 

question—because the drug department of the store 
could not possibly be carried on under existing cir-

stances unless a qualified person were there— 

from what they are now sowing what do they intend 
to reap in the future? They are sowing undoubtedly 

for the destruction of the ordinary retail trade. The 

only question is, have they to bear the loss? In 

their latter days that advantage which they may 

hope for. They have a present prospect, in lending 

themselves to these stores, of shorter hours and of 

slightly augmented salary, as compared with 

what they would obtain at the hands of the retail 

chemists—latterly to the drug department, but I would urge upon qualified men the necessity of con-

sidering their position before they accept any of the 
situations thus offered by the stores. The question is 

a very large one and, of course, in any legislation we 

shall never get what we want, for legislation is, after 

all, only the end, and to obtain the end we all desire we should employ all the means; and if we have not 

out our whole body. With that unity we may be able 

to obtain what we require at the hands of Parliament. 

We may then be able to administer it in such a way 

as to place us in the position of other professional 

bodies, and to the satisfaction perhaps of the com-

nunity at large. Major Certificate must be a future 

and not a past question. After all we do not claim to be 

protectionists in every sense of the word, but we do 

claim that our members, especially as they have to 

undergo a special training, should have the assist-

ance of Parliament in this matter, in order that we 

can retain our position of responsibility, and not be 

overdone by those who are quite outside the profes-

sion, and who have no business to be in the pharma-

cy. I am quite sure that the Council in any future action will 

not lose sight of this view of the question, which I 
hope before we close the proceedings to-day will be 

spoken to by others in more fitting language than I 
have been able to use.

Mr. Taplin: I have only a few words to say, but, 
in the first place, I wish to point out, as Mr. Mac-

kenzie has already done, that the pecuniary benefit 

derived from the sale of drugs should not be received 

by anybody but those persons who are upon the 

register. The medical profession is protected to a 

large extent, although I think, when I stated this before you 

objected to my so doing.

The President: There is no protection in the 

medical profession in law. It is no use beating about 

that bush.

Mr. Taplin: All the training which people have 
to undergo in order to qualify themselves to trade as 

chemists and druggists is utterly useless unless it 

gives us some protection. All over the country shops 

are selling things which ought only to be sold by 

chemists and druggists. So long as an outsider can 

put his money into a concern and sell articles which 

really should only be sold by chemists and druggists, 

I consider that it is no use whatever to put money 

into this Society.

Mr. Lomas: I shall not trouble you with any ob-

servations about the Research Laboratory, because I 

think we have had quite enough of that already, 

but I do wish to say a few words to the Society as 

prosecutors. I remember, sir, some few years ago in an 

address which you delivered to the members you 
said the time would come when the Society would 

cessate to be prosecutors under the Pharmacy Act. 

I do not know whether you remember that, but I do. 

I, for one, think the time is very near when the 

Society would do well to shift their ground from 

Government Department, and that the Society 

should cease to be prosecutors under the Pharmacy 

Act. What do you get by it? Nothing. But the 

loss is considerable. I have looked through the 

report which I have in my hand, and I fail to find any-

thing about the expenses connected with the prosecu-

tions that have been undertaken by the Society. But, 

anyhow, you may rest assured of this, that if there was 

a considerable sum to the good you would not be able 

to retain it, but would have to hand it over to the 

Government department. But it seems to me that if 

the amount has been on the wrong side, the loss you 

have to bear is far better than the valuable time given 

to these prosecutions could be far better utilised in 

strengthening the position of the Society, as your 

members have been telling us to do—to protect us 

against outsiders. You have a Parliamentary Com-

mittee—what have they to do? They have to 

look out for prosecutions which do no good to one. 

On the contrary, they do us harm in every possible 

way. Some time ago I stated that they might do good 
in this respect, that they would make the Society 

known, as it would be talked about by the 

public. But times have altered now. The only 
effect of instituting prosecutions is to raise the 

tension between the Society and the Government, 

and let the Government undertake the prosecutions, we shall 

find that they will be far more active than you will in 

the matter. I think you said before that the Council
was fully occupied; and that being so, I would suggest that the Parliamentary Committee should cease prosecuting, and devote their attention to legislation to protect the members. You have Scotch members, they are long-headed; if Englishmen cannot do it, bring in Scotchmen and let them do it. I would say, bring in Scotchmen to protect the members. Get Members of Parliament to look after our interests in the House of Commons. It is in that way that you will be able to strengthen the position of the Society. I do not see any other way in which you can do it. I have often touched upon this. I have no objection to it. Mr. Carteighe has been too long idle; I think it should be neglected no longer; and I hope the new blood that comes in will take this matter into consideration. Now just a few words upon the Library. Upon one occasion I went to the Library, and after groping about in darkness among the magazines I was able to get what I wanted. But when I got it I wished to make a few notes, and going to the table for that purpose I found that the tables were fully occupied by students. If that occurs very often I think you should provide more table accommodation in the Library, and a little more light where the magazines are. Upon a former occasion I said a few words about the "lawyers". What is there in this—Take your stand upon this: no matter what the quantity, so long as the article contains a scheduled poison it comes within the Act. Never mind what the lawyers say—you know what they are—stick to all; get all you can, and if you cannot get all, get as much as you can.

Mr. Atkins: It is some years, I think many years, since I spoke at an annual meeting, as we have an unwritten law amongst us that the representation of the Council at this meeting should be left in the hands of the President, and I think a very wise understanding it is; but I wish for one moment, and only for one moment, to depart from that practice to-day. I do feel it incumbent upon me to utter a very emphatic word with regard to the remarks made by my excellent and worthy friend Mr. Butt. What I want to say is this. Personally I have all along very largely shared with him, and I know with others, the desire that the Research Laboratory should have a very much more direct pharmaceutical bearing that it has hitherto had. I quite believe with the different speakers that the area and department of practical medicine, the thing with which the ordinary rank and file of the public are and will be interested, is present to the Medical profession for the next hundred years or more if the Research Laboratory exists, it will find abundant material in pharmacy. But having said this, what I want to take upon myself to-day as a member of the Council is a share of the responsibility in the conduct of that Research Laboratory. I must confess that with very deep regret I have heard the somewhat personal attack made upon the President. Now, gentlemen, I have in days gone by in this room uttered very warm eulogies of the President, and I have said little of late, because I know he knows my heart and my esteem for him, but I do wish it to be placed on record to-day emphatically that it is my own conviction that we have in Mr. Carteighe a man who has devoted the splendid powers which God has given him, and for which he might be well thankful and we thankful, too, with no undue generosity. The worst you can make this remark emphatically at this meeting, because a rumour is in the air, and it may have some substance, that this is the last year of Mr. Carteighe's presidency. I offer no opinion upon that point here. It is not for me to say whether it shall or shall not be, except if I am re-elected as an individual member of the Council. But for the first four years of his Presi- dency I was his Vice-president, and I then knew the amount of work which he gave to this Society. Of course I am perfectly conscious that, as his Vice-president having a strong man as President, with strong judgment and a marvellous tenacious memory, my work was a very humble one, but I wish to say that those of us who have been privileged to serve under Mr. Carteighe gave an enormous amount of his time to the business of this Society, and I believe that the work since has largely grown. Do not let this, if it be the last year, for one moment be overshadowed by any sense of depreciation whatever. I do wish to say eventually that Mr. Carteighe may be so long in the darkness that has served us to the very best of his light and ability. Just one more word, which I will touch with the lightest hand, because I speak of Mr. Butt as a valuable friend of mine whom I greatly esteem. I do deeply regret that he has touched in the closing part of his remarks upon a much vexed controversy. I think that the less we say here upon that matter the better. The Council did take wisely and properly an action with regard to that matter, and there the question I think may rest. It is not for me to attack the character or the ability—for both I consider have been attacked of a man who has always borne his name and made himself heard. We have always felt, in going through life, that when the character of a public man is attacked, if the attack is vindicated and justified that England is the poorer. It is a big word to utter. I say this emphatically, I have strong political convictions which I never express in ordinary assemblies. I do not care who is the leader, whether it be of one party or the other, but if I hear that man's character traduced, and he is represented as being not an honest or moral man, I say whoever makes the charge, and he can prove it, that England is the poorer. I say the character of every man upon the Council for honesty and integrity is the dearest thing we have. If you steal my purse you take trash, but if you take my good name from me you take God's greatest gift. I say let us hold our judgment in suspense. Great questions, purely technical and scientific, must come before tribunals composed to deliberate with them, and the final Court of Appeal scientifically has pronounced its judgment upon integrity of work I shall bow most loyally to it. I have shadowed out my ideas. I came into this room with the absolute intention of not saying one word, but I do feel I shall not depart this room red-faced, save it is for what Mr. Michael Carteighe has done for the Society, and my desire with regard to the much vexed question of a particular controversy that we should hold our judgment in suspense.

Mr. Erskine: I think with Mr. Atkins that the less said upon this matter the better; in fact, I almost wish that Mr. Butt's speech had been left severely alone. I do not like to question what you do in the chair, but I must confess that I was astounded that you let him go on for the length of time you did. It is impossible to enter into the controversy in this room. I am sure Mr. Butt must have done it unconsciously, but he has given an absolutely unfair and garbled account from beginning to end. This matter has been sat in judgment upon by several men who have given a considerable amount of time to the consideration of it, and the charge that has been brought against this Society has been proved to be absolutely untrue. I am sorry to hear Mr. Butt's speech in this room. Mr. Butt makes unfair insinuations; he said you were seen coming out of the archway of Burlington House, and if that means anything it means, I suppose, that we had a committee meeting in the rooms of the Royal Society. All I can say is it is absolutely untrue. I suppose the inference was
that meeting there we should be more or less under the influence of Professor Dunstan. It was merely for the convenience of Professor Dunstan and the members that we met in the rooms of the Royal Society, and Professor Dunstan was only there for a short time to answer our questions. Any attempt to show bias is absolutely out of place. I will say this of Professor Dunstan, that we are all agreed that the Pharmaceutical Society is in better hands than before, and that his influence has increased. The Council has had that under their consideration, the Research Laboratory has had it under theirs as to whether it would be possible for him to continue his work. But his work in the past has been thorough. One great thing which has not been mentioned is his enthusiasm in teaching the students. This is the first time in our history where there has been any possibility to teach students higher research. I am almost afraid to mention the word, because some gentlemen seem to think that we are doing too much, and so forth. As to the aforesaid research, that was started by our friend T. B. Groves. He carried it up to a point and said I can carry it no further, and the Research Committee are aware how it has grown and monopolised time; in fact, we have considered whether we should pull it up or not, though up to the present when it is done, it must go on. It has given the appearance that the Research Committee has been alive to more pharmaceutical requirements. The equipment of the laboratory with men who are now qualified to make proper and necessary investigation is considerable, and if we are to take an active part in the formation of the Pharmacopoeia, I think the Research Laboratory will redound to the credit of the Society, and be of much help. I could not leave this meeting without saying something in favour of Professor Dunstan, who, I consider, has been attacked behind his back. It is only justice to him to say that, so far as the Research Committee is concerned, Professor Dunstan's labours have been worthy of all praise. Of course, the time may come—perhaps it is already come—when Professor Dunstan will have to elect what work he will carry on. We, as a Society, ought to be proud of a man who has raised himself to the position he has. It is no accident, or result from the stimulus of a single person in the Society. He is our own product, and instead of crying him down I think we ought to be proud of him.

Mr. Giles: The motion before the meeting is the adoption of the report and the accounts, and it would be extraordinary if no one asked a question on the accounts. Although I am perhaps the last person entitled to ask it, I think it is desirable that a question should be asked by this meeting. I have only had the accounts in my hand for a few minutes before the meeting; but they appear to show an excess of expenditure over income of between £1600 or £1700. That is not a material thing if it is exceptional, and will not occur again; if this is a thing which has to be accepted as the perpetual condition of things it is somewhat alarming; and I simply rose to call your attention to it that you might give some information which might be encouraging on that point.

Mr. Mackenzie: I should like to ask whether it is competent for a person to make personal attacks upon anyone when he has not ended it with a motion? It is no part of the report which is before us, and if that is so I hope we shall not consider it. I think it is the rule of the house to confine the debate to the report itself as to the questions with regard to accounts and like, as they are not in the report, and have not been followed by a motion, that they ought not to have been mentioned.

Mr. Butt: It is in the report of the Research Laboratory Committee.

Mr. EWING: I should like to express on behalf of my friends in the northern part of the country, our thanks for the hospitality of this Society. We have had provided by you, and by your Council, a set of rooms for examination purposes, and a hall which is a credit to the Society, and I have not the slightest doubt, as my friend Mr. Mackenzie said, it will go far to strengthen the hands of the Pharmaceutical Society in its investigations. I do not believe, however, that it is my duty and my pleasure to thank you all for your kindness and for your untinted liberality. I do not wish to enter into this unfortunate and much vexed question of the Research Laboratory. Like Mr. Atkins I wish to withhold my judgment in the matter, if it is not possible to have the matter settled in a manner in which the public approval of the members of the Society can be obtained; I can only say that I thank you all on behalf of the Executive of the Northern Branch for your kindness to us.

The President: Gentlemen, I do not feel particularly under a cloud—and yet in a sense I am under a cloud, because people accept garbled statements of what has been going on in the Council chamber, which should be private, as being true representations of such statements. That is what I am suffering from; that is all. I am not going to refer further to the observations of Mr. Butt. It is very good of him to take the opportunity of pronouncing a funeral oration upon me. It is well timed; it is the proper time. Of course, I have been a great nuisance; that is not my fault, it is the fault of other people; but I know one thing, and that is that there is more than one officer of this Society who would be glad if Michael Cartheige were here. If you want an officer of the Society who is not like a strong President. I consider that is possible, and in this particular instance I think it quite time for me to make my bow. When I say that I am obliged to Mr. Butt for giving me this funeral oration, I mean exactly what I say, neither more nor less, I am not saying that it is fit to do, everything he has said. He has made a number of statements which are incorrect to say the least of them; these statements refer to something which is not before us, something which is private and confidential, and forms part—I was going to say almost a quarrel—which is not before us, though if it were I should have something to say about it, and I think possibly there might be a difference of opinion as to whether several officers of this Society might not be talked to seriously. It is not fair for you in a meeting of this sort or for anyone to bring forward a statement of this kind. The general question may be raised fairly enough, but a personal question in a body where we cannot speak freely and which is in the hands of the Council, and it is unwise to bring forward. I hope Mr. Butt will not consider I am disrespectful to him. I know him very well; I know his power of occasionally saying things which he does not intend to wound, but which do wound; and I know that more than once we have felt how useful Mr. Butt would be upon the Council if it were not for his over-frankness perhaps, and his over- desire to state the naked truth in a somewhat brutal way. The reference that he has made to certain
gentlemen who are associated with the President and Vice-president in certain work is, I think, unfortunate. Whenever the Council asks men to join a committee for specific work, it ill becomes a person who has not the responsibility of a Councillor upon his shoulders to criticize the move, especially when a number of honorable and not only honorable, but distinguished men—men who are doing good to the Society by coming to its dinners or entering its portals—men who do good to the Society whenever they come in contact with the President. What do we want? We want to extend our power and usefulness. What has been done by the President? Now, how is that to be done? Not by talking to each other. Some of us want to go to Parliament, and that is right enough. How do we want to make the work of the Society known? It is no use talking to ourselves in our Journal. You want to spread the news far and wide, and everything that is published from our Research Laboratory, which goes all over the world into the hands of people who are not pharmacists is, to put a vulgar phrase on it, a good advertisement for this Society, and it brings with it a respect which you cannot make up for by going to Parliament. In my journey in the States, there was not a single professor of chemistry that I met who did not pay the highest compliment with regard to the work which has come out of the Research Laboratory. But I will let that pass.

Mr. Mackenzie has referred to company trading, and the clumping of expenditure, and so on, and so has my friend, Mr. Campkin. The Council has referred a number of things for early consideration to the Parliamentary Committee, which will no doubt be reappointed when the new Council meets. The question whether you should have a Bill, that is to say, the number of things which should be submitted to the members before we go to Parliament, has not yet been decided upon. There are others who think the consolidation of the Society might be the best thing to do per se—I mean to say, consolidation such as we drafted a year or two ago, which would give the rights and privileges which are now not obtainable under the Act by associates in business—I say such a Bill as that would tend to consolidated the Society and encourage the great mass of the trade to come into our ranks. If we could do that we should be doing so much with. I must admit that the difficulties surrounding this subject are very serious. There is a good deal of work which is done by the Council in Committee, which is done by your officers in connection with Government departments, which sometimes promises to give hope of getting some alleviation, and the Council, through the President, have been acting during the last few months in more ways in connection with this grave subject. There is more than one way of attacking this kind of bogus company trading—namely, the direct way and the indirect way, and both processes have been considered by the Council. The direct attack upon what most people would call ordinary company trading is excessively difficult. With the immense amount of capital at command, anybody ready to lend money at a small rate of interest, it is no wonder that every kind of occupation should now have a tax of 5, or 6, or 7, or 8 per cent, and so suffer more in proportion because of the very smallness of our returns, but it is a serious matter for the nation as a whole. It is a big question—it is a question of national importance. I do believe that before long a department of Government will have to face this thing and will probably deal with it in some way which will be at least a slight benefit to us and to every small tradesman. On the other side, if I were to give evidence before a Select Committee as to the injury done to chemists and druggists, I think the chairman would probably point to the number of candidates coming up. How it is that with this dreadful condition of business, the numbers who wanted to come into this craft, which we say is not worth coming into, is so great. I am bound to be frank with you. I have to carry to others the opinions which you utter in this room. I have to fight your battles before the councils of the trade, and I have to be on sound ground. With reference to the question of what is the good of the Act, I think we may congratulate ourselves upon the fact that whatever the defects of the 1888 Act, we certainly should have been worse off in the great struggle if there had been no Act at all. I feel certain if we have done nothing that the educated man has been able as a chemist and druggist in many cases to save himself from absolute ruin, to say the least of it, he has been able to exist. If the chemist and druggist had not been registered, the condition of the whole of their profession would be worse than it is now. It is not much protection given in this country to any form of professional occupation. There is very little of that real protection, though there are certain indirect ways of getting protection just as there is in our case. We have the exclusive right in a sense to sell and dispense poisons. In an individual sense that is correct, but in another sense, that is in the case of a company trading, it is incorrect.

The only properly constituted professions that I know of in this country are those of the Bar and Solicitors. The solicitors have a perfect system of trading and examination and a proper set of restrictions governing all calling in that way, but with that they are responsible to a big authority; they have to be on the rolls. They pay nine guineas every year to have their names properly kept on the register, and they are amenable to be brought before the Incorporated Law Society for any slight deviation from the strict duty. So are the Bar. Where does that come in with the chemists and druggists? If we run on the professional line or up the professional ladder we must be prepared to take the responsibility, and it is not everybody who will undertake to do that. We have not the power to be responsible to a big authority. There is no serious offence. We are only part of the way on to a profession, and the question is whether, if we go the whole way, and desire to be so registered, whether we must not follow either a compulsory or voluntary code of ethics which many of our men are at present unable to bear. When I speak about medical men not being protected, I am quite aware that under the Apothecaries Act prosecutions may take place, but the power of prescribing or of doctoring is practically open to everyone except a chemist and druggist. We are referred to in the old Apothecaries Act. It is the chemist and druggist the prosecutors have gone for when they think he is prescribing, but as a matter of fact as long as a person does not use the title he can carry on the greater part of what is called medical practice. Theoretically he cannot sign a certificate of death legally, but I can put my finger upon a place in the United States where the doctors of law who were signed by persons who were not registered, and the certificates were never questioned. We are badly off, and some of our medical friends are not much better. We who live, some of us by dispensing the prescriptions of the shining lights of the profession are apt to look upon them as being representatives of the whole medical art, but I think there is almost as
much struggling in the medical profession, or if not there soon will be, as there is in our case. They are suffering from the effect of capital. Great bodies got men to do work for a small pay, and so the wheel goes round, and the personal increment is reduced year by year. Whether that is on the principle of greatest good to the greatest number I do not know, but some say it is. Then Mr. MacKenzie referred to clumping. The fact is, we have a Committee to draw up the form of our accounts, and there is great inconvenience sometimes in giving details for the purpose of criticism. We do not object to criticism, but it would be impossible for your President to answer many of the questions put to him, if we gave many details in these accounts, without doing some damage to our own interest. I must appeal to you as men of business, for many of you, when you go to company meetings, know that the Directors always consider what they shall publish in the shape of accounts. I do not think that a Society like ours, at the annual meeting, need go into too much detail with regard to the accounts. You may criticise the total expenditure in a department, but there is a positive disadvantage about it, and we have thought it wiser with regard to the law and sundry other accounts, to put the balance on whichever side it is. We have thought it wise with regard to the Journal to put the total on one side as against the total upon the other. We are not ashamed of our accounts in any way, but there are reasons why, when we are carrying on in some department a business, we do not care to disclose every little detail. It is not that we are afraid of criticism. I am afraid the custom of giving a statement of receipts and expenditure was begun in the early days of the Society when it was comparatively poor, when a question of £10 on one side or the other was a matter of moment. That custom grew up and we followed it, but I know of no other incorporated body which goes into so much detail in presenting the report as we do. With regard to the question put by Mr. Giles, I must refer him to the first paragraph of the report, where he will see we refer to the fact that we have paid £2000 out of revenue for the enlarged premises in Edinburgh. It is not the revenue for the year, but that which is just over. Out of the income of 1893 and 1894 combined we have paid £2000. We do not hope that that will go on. Our friends in Scotland will no doubt be at us before long, but we cannot afford to let them have many more thousands. There is some balance due to them at the present moment, and we hope to pay that out of revenue this year. The resolution for the adoption of the report was then put and carried unanimously.

APPOINTMENT OF SCRUTINEERS.

The President then read a list of names of gentlemen who had been nominated to act as scrutineers, and their appointment was unanimously agreed to.

APPOINTMENT OF AUDITORS.

The following gentlemen were appointed to act as auditors:

Butt, Edward Northway, 77, Hamilton Terrace, N.
Leitcher, Frank Harwood, 60, Bartholomew Close, E.C.
Stacey, Samuel Lloyd, 22, Great St. Helens, E.C.
Umney, Charles, 50, Southwark Street, S.E.
Yates, Francis, 64, Park Street, Southwark, S.E.

The President then called attention to the fact that the following registers had been laid upon the table in compliance with the provisions of the Act:

Register of Members, Associates, and Students of the Society.
Register of Pharmaceutical Chemists.
Register of Apprentices and Students under the Act of 1862.
Register of Chemists and Druggists under the Act of 1868.

The President: Gentlemen, I have now to move that the meeting adjourn until 3 o'clock to-morrow. Mr. Butt: Gentlemen, before we leave I think we ought to propose a vote of thanks to the President. I should like to say this much, that Mr. Carteigh is a personal friend of mine, and if I have said anything with regard to him which is outside the range of proper criticism, I much regret it. The motion, having been seconded, was carried, and the meeting then adjourned.

ADJOURNED GENERAL MEETING,
Thursday, May 23.

Mr. Michael Carteigh, President, in the Chair.

The adjourned meeting for receiving the report of the Scrutineers was held on Thursday, May 23. The Chairman of the Scrutineers, Mr. E. N. Butt, read the following report:

SCRUTINEERS' REPORT.

We, the undersigned Scrutineers, appointed at the Fifty-fourth Annual General Meeting of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following:

Voting papers reported by the Secretary to have been issued.... 3800
Voting papers received...... 3249
Voting papers issued but not returned 1751
Voting papers received...... 2049
Voting papers disallowed:
Informal........ 20
Received by post too late.... 85 85
Voting papers registered 1894

Result of the Poll.

Martindale 1749
Carteigh 1734
Atkins 1672
Hills 1661
Bottle 1617
Newbolme 1596
Allen 1593
Hampson 1591
Southall 1559

W. K. Hopkin.
Albert Fellows.
R. F. Young.
Wm. Fletcher Gadd.
Herbert Cracknell.
S. A. Stuart.
Robt. H. Jones.
J. R. Wretts.
W. Prior Robinson.
Jas. Spilsbury.
J. C. Hyslop.

Edward N. Butt, Chairman.

W. C. Birch.
J. H. Shacklock.
A. E. Tanner.
Edward B. Stamp.
D. R. Jacks.
P. J. Robbins.
F. Bascombe.
John Holding.
James H. Gradidge.
W. Metton Holmes.
P. Davidson.
C. H. Fairrow.
The New Council.
The President, as Chairman, then declared that the following gentlemen would constitute the Council for the ensuing year:

Allen, Charles Bowen, 20, High Road, Kilburn, London, N.W.
Atkins, Samuel Ralph, Market Place, Salisbury.
Bottle, Alexander, 57, Townwall Street, Dover.
Carter, Michael, 180, New Bond Street, London, W.
Cross, William Gown, Mardol, Shrewsbury.
Corder, Octavius, 31, London Street, Norwich.
Gostling, Thomas Preston, Dids, Norfolk.
Grose, Nicholas Male, 8, Temple Street, Swansea.
Hampson, Robert, Knole Paddock, Sevenoaks.
Harrison, John, 33, Bridge Street, Sunderland.
Hills, Walter, 225, Oxford Street, London, W.
Johnston, John, 45, Union Street, Aberdeen.
Martin, Nicholas H., Northumberland Road, Newcastle-on-Tyne.
Martindale, William, 10, New Cavendish St., London, W.
Newsholme, George Thomas Wilkinson, 74, Market Place, Sheffield.
Savory, Arthur Ledsam, 143, New Bond Street, W.
Schacht, George Frederick, 1, Windsor Terrace, Clifton, Bristol.
Southall, Alfred, 17, Bull Street, Birmingham.
Storrar, David, 228, High Street, Kirkcaldy.
Warren, William, 24, Russell Street, Covent Garden, London, W.C.
Young, John Rymer, 42, Sankey St., Warrington.

The President next thanked the Scrutineers for their services, and, Mr. Butt having briefly responded, the latter gentleman was specially thanked for acting as Chairman of the Scrutineers, after which the meeting terminated.

Proceedings of Societies in London.

Western Chemists' Association (Of London).

At a meeting of the above Association, held on Wednesday, May 15, the President (Mr. R. H. Parker) in opening a discussion on "The Present Phase of the Poisons Law," drew attention to the serious anomalies existing in the law as recently interpreted; first, in the matter of labelling various dilute preparations "Poison" while carbolic acid is under no restriction; secondly, in the matter of selling poisons, a competent assistant of six or eight years' experience; not being legally allowed to sell a packet of oxalic acid without supervision; and lastly, in the matter of keeping open shops, for while a pharmacist is subject to all the pains and penalties of the Pharmacy Act, a limited company is declared to be outside the operation of the Act, and consequently free from many of its restrictions. The law, therefore, harasses the qualified chemist and gives outsiders a loose rein. Mr. Parker pointed out that the existence of these anomalies was not the fault of the Pharmaceutical Council, nor was the remedy at present in their hands.

The fault lay in the blind rigidity of legal interpretations, and the remedy consisted in the united demand by chemists for a rational construction or amendment of the Pharmacy Act. Clearly trade protection pure and simple, and the prohibition of company pharmacies which are under the management of a qualified chemist, were neither necessary nor possible at present. The fundamental principles of an effective Pharmacy Act might be included under two headings; (1), The public must be protected from the untrained and incompetent medicine vendor; and (2), The trained and competent pharmacist must be protected from unfair competition. These desiderata might be secured by the following regulations:—Every shop or place open to the public for the sale of articles enumerated in the poisons schedules, or for the dispensing of medical prescriptions, should be registered, together with the name of its bond-fide manager and of its owner or owners. The manager must be a qualified chemist, and must give his whole time and attention to one pharmacy, must be held responsible for the proper conduct of that pharmacy, and may have his management certificate (his Minor diploma) suspended or cancelled for gross inattention or misconduct. Any pecuniary penalties incurred should be borne by the manager, or, in default, by the owner or owners. An assistant's qualification (which may be a portion of the Minor) should permit dispensing of prescriptions and sale of scheduled poisons in a registered pharmacy during temporary absence of the manager, the latter being responsible for the assistant's conduct. All poisons and dangerous substances should be scheduled for sale in registered pharmacies only. The phrase and "its preparations" to appear in Part II. only. The use of the "poison label" for articles in Part II. to be left to the discretion of the manager.

The following resolution was submitted to the meeting: "That this meeting, while supporting the policy of the Pharmaceutical Council in its administration of the Pharmacy Act under recent interpretation, is of opinion that future legislation should be directed towards the joint regulation of every pharmacy with the names of its qualified manager and its owner or owners, the manager to be held responsible for its proper conduct, and, together with the owners, for any pecuniary penalties that may be incurred. That the qualifying examination should be divided to admit of an assistant's qualification, and that the matter of labelling poisonous substances should be largely left to the discretion of the manager or the pharmacist." Mr. Andrews agreed with most of Mr. Parker's suggestions, and referred to the existing impossibility of supplying every chemist with a qualified assistant.

Mr. Tapslov thought that a clear rule for labelling poisons should be established, leaving no doubt as to the chemist's procedure. Mr. Marsh considered it very desirable to insist upon the principle of a separate manager for each shop, and that the manager's name should appear on all labels.

Mr. Hyslop said that there were a great many good points in the present Pharmacy Act, and he thought it would be better to amend it rather than commence de novo. He suggested a section of the "Poisons Schedule" for sale in licensed places other than pharmacies, but Mr. Marsh pointed out that such would form a dangerous precedent.

Mr. Gulliver drew attention to the difficulty that would be involved in supplying outlying districts with pharmacies, sold only in registered pharmacies.

Mr. Andrews said that the proposition before the meeting was most important one, requiring careful consideration and an extended expression of opinion, he therefore proposed that the discussion be continued at a next meeting, the meeting adjourned until June 19.
Notes and News.

Revision of the British Pharmacopoeia.—The British Medical Journal announces that nearly 5000 answers have so far been received to the circular (ante, p. 1018) recently sent out by the Therapeutic Committee to members of the British Medical Association in reference to the revision of the B. P.

Dental Hospital of London.—The thirty-seventh report of the governors of this institution shows that the probable cost of the site and building for the new hospital will be £40,000, of which £14,000 is yet required, and friends of the hospital are asked to assist in covering this amount.

Practical Botany.—Summer schools for the practical study of botany are conducted in the United States, and Nature announces that several will be held this season—those in connection with Cornell University and the University of Wisconsin from July 8 to August 16, and that in connection with the Cambridge Botanical Supply Company for five weeks, beginning July 5. Home universities might well make a note of the fact and do likewise.

The Isolation of Argon.—Attempts by H. Moissan to produce argon compounds with rare elements which unite with nitrogen have failed completely—titanium, boron, lithium, uranium, and fluorine all yielding negative results.

Practical Photography.—The London Technical Education Board is said to be contemplating the establishment of a school of practical photography, mainly for the purpose of training workmen in the production of process blocks, half-tone work, photolithography, collotype, photogravure, and other substitutes for wood engraving now largely used by the illustrated press. Most of the skilled workers at these processes are foreigners, and the Board is anxious to establish a school that may be able to exert an immediate and direct effect on an important industry and to benefit a large class of skilled workers.

Dr. Thorne Thorne and the Medical Council.—Dr. Richard Thorne Thorne, C.B., F.R.S., the principal medical officer of the Local Government Board, who succeeds Sir John Simon as a member of the General Council of Medical Education and Registration, was born at Leamington in 1841, and educated at Mill Hill Grammar School, at the Lyceé St. Louis, Paris, and at St. Bartholomew's Hospital. He took his M.B. degree at London University in 1865, and qualified as a F.R.C.P. in 1875.
